9583. GIAJA, J. Sur la production de chaleur de quelques homéothermes dans la lutte extrême contre le refroidissement. [In Serbian, with French summary.] *Bull. Acad. Roy. Serbe Sci. Arts, Belgrade* 135(64): 23-31. 1929.—From a certain number of comparative measurements of the peak and basal metabolism of animals, both mammals and birds, of varying size, the following conclusions may be drawn: The peak metabolism is no more directly proportional to body mass than is basal metabolism, but varies inversely therewith. In relation to body surface the peak metabolism exhibits differences between species that are often quite marked, but less marked than those that are found when peak metabolism is related to body mass. Although it is not possible to formulate a law governing the relationship between body surface and peak metabolism it is plain that surface area is one of the most important factors governing this upper limit of metab-

olism. The same conclusion is thus reached as in a previous memoir on basal metabolism. The ratio between the peak and basal metabolism of different animals varies generally within fairly narrow limits. From this it follows that the peak metabolism is not related to the ability of the homeotherm to resist cold. Similar values were found for the swallow, the sparrow and the duck. The hedge-hog has a peak metabolism of the same order as other non-hibernating homeotherms, showing that hibernation does not influence thermogenic capacity.—*From author's summary (transl. by J. R. Earp).*

9584. GLOVER, EUGENE C., GENEVA A. DALAND, and HENRY L. SCHMITZ. The metabolism of normal and leukemic leukocytes. *Arch. Internal Med.* 46(1): 46-66. 1930.—For the study of O consumption of the white blood cells, white blood specimens from 14 patients with myelogenous leukemia, 8 patients with lymphatic leukemia, suspensions of leukocytes from 18 patients with myelogenous leukemia, 10 patients with lymphatic leukemia, 6 patients with leukocytosis from various causes and 7 normal persons were studied. For the study of glycolysis, suspensions of leukocytes in plasma were prepared from blood specimens of 16 patients with myelogenous leukemia, 15 patients with lymphatic leukemia, 4 patients of an unclassified type of acute leukemia, and 11 persons with normal blood. The leukocyte metabolism of the leukemic blood was found to vary according to the degree of maturity of the cells. The O consumption is greater, the more mature the cells, whereas the sugar consumption (glycolysis) tends to be smaller. When calculated on the basis of weight, the rate of sugar consumption of lymphatic white blood cells does not differ from that of myelogenous cells of approximately the same degree of maturity. The metabolism of normal white blood cells is similar to that of relatively mature cells from patients with leukemia, but more active, as regards both O and sugar consumption. Slight degrees of cell injury exert a marked effect on the rate of O consumption, much less on the rate of sugar consumption. When measured under aerobic and anaerobic conditions (in the presence of 95% O and 95% N, respectively) the sugar consumption of normal white blood cells and mature myelogenous cells from leukemic blood resembles that of cancer tissue, whereas the sugar consumption of immature myelogenous cells and of both mature and immature lymphatic cells is of the type considered characteristic of embryonic tissue.

9585. GROEDEL, FRANZ M., und RUDOLF WACHTER. Über den Gasstoffwechsel im Süsswasser-, Sole-, Luft- und kohlensaurem Wasser- und Gasbad. *Veröffentl. Zentralstelle Balneol.* Neue Folge Heft 16. 56p. 8 pl. Richard Schoetz: Berlin, 1929. Pr. 4 M.—The technic of determining O consumption in the various baths is given. Numerous curves illustrating the results of O used, CO_2, respiration and respiratory quotient in healthy people are shown, as well as tables giving the effects of the baths. There is a discussion of the results, a brief discussion of the literature and extensive summary. There is a short section on the effects of these baths in patients with circulatory disturbances.—*E. A. Baumgartner.*

9586. HAHN, AMANDUS, und W. HAARMANN. Über Dehydrierungsvorgänge im Muskel. *Zeitschr. Biol. [München]* 89(6): 563-572. 1930.—*In vacuo,* and without the addition of an H acceptor, it has been shown by experiments with muscle-brei of warm-blooded animals that succinic, fumaric, malic, lactic and citric acids are dehydrogenated to pyruvic acid. Whence it is concluded that H acceptors exist naturally in muscle. The dehydrogenations take place also in the presence of HCN, a fact which excludes the possibility that they are the results of O remaining behind in the muscle preparations.—*A. Hahn (transl. by C. D. Snyder).*

9587. HEILMEYER, LUDWIG. Klinische Farbmessungen. VIII. Mitteilung. Die Harnfarbstoffausscheidung beim Morbus Basedow, sowie im Thyroxinversuch, zugleich ein Beitrag zur Frage der Beziehungen zwischen Stoffwechsel und Harnfarbe. *Zeitschr. Ges. Exp. Med.* 72(5/6): 545-560. 1 fig. 1930.—In 12 cases of Basedow's disease the urinary coloration was determined, and, in 3 cases (which also showed enlarged liver or other signs of thyrotoxic circulatory damage), was found above normal. No relation could be established between urinary coloration and heightened metabolism. Even cases with +130% heightened metabolism showed no increase in urinary coloration so long as circulation remained normal. Thyroxin and thyroidin in therapeutic and distinctly effective doses produced no change in urinary coloration or in the fecal or urinary urobilin. Thus these observations do not sustain Drabkins' hypothesis of a relation between heightened metabolism and increased urinary coloration.

9588. IRVING, LAURENCE, and H. C. FOSTER. The respiratory quotient of resting mammalian muscle as shown by the eviscerated decapitated cat. *Amer. Jour. Physiol.* 95(2): 429-445. 1930.—After evisceration of a decapitated cat there is a tendency toward over-ventilation. When the ventilation is reduced, the preparation may be kept in a state of balanced CO_2 equilibrium with R.Q. near 0.80. The balance of the CO_2 equilibrium can be controlled only by establishing the fact that the CO_2 content of muscles does not change. Arterial and venous blood are not reliable indicators of CO_2 balance in the eviscerated preparation. The R.Q. is not much greater than that of the entire animal, and shows that resting muscle oxidizes about the same substances. Intravenous administration of glucose causes a slight elevation of R.Q. to an average level about 0.85. The tendency toward over-ventilation is relieved, and the muscles even gain CO_2. With massive doses of insulin and glucose the tendency toward CO_2 retention in the muscles is more marked. The average observed R.Q. was 0.88, and the correction for CO_2 retained in the muscles raised the R.Q. to 0.94, indicating diversion of oxidation to the principal use of carboyhydrate. The correction of the R.Q. for the amount of CO_2 lost from muscle during slight over-ventilation indicates that only muscle is appreciably altered in CO_2 content. The action of insulin and glucose, in addition to increasing carbohydrate oxidation and glycogen storage, affects the CO_2 equilibrium of muscle, probably by increasing its capacity.—*Authors' summary.*

9589. JAKOWENKO, W. A. The effect of sun and air and air baths on the respiratory gaseous exchange in man. *Amer. Jour. Hyg.* 10(1):165-182. 1929.—The height of the respiratory gaseous exchange in man during sun baths and air baths depends upon temperature, humidity, air movement and intensity of solar and skylight radiation. Rate of air movement is of greatest importance. Climatic factors may be divided into 2 groups according to their effect on the gaseous exchange in man, (1) those increasing the gaseous exchange, such as low temperature and air movement, and (2) those factors which decrease the gaseous exchange such as high air-temperature, absence of air movement and excess of heat produced by solar radiation.—*W. C. Russell.*

9590. KAGAN, E. M., und P. M. KAPLAN. Untersuchung der dosierten und maximalen Arbeit bei Personen von verschiedener physischer Leistungsfähigkeit. *Arbeitsphysiologie* 3(1/2): 61-119. 5 fig. 1930.—The object of the investigation was to determine in what manner limited and maximum work would give knowledge of the differences in the physical capacity for work. Three groups were studied, porters, mental workers and an intermediate group. The work consisted of lifting a load of 20 kgm. from a level of 0.5 meters to a height of 1.5 meters 16 times per min. The respiratory exchange was determined with Douglas bags and analyses of the expired air by the Haldane method. The first series was a study of work of 1200 kilogram-meters in 3 min. and 20 sec. The respiratory exchange was measured during the period of work and during the recovery periods of 1.5, 1.5, 3, 3, 6, 6, min. successively and until recovery was complete. In the 2nd series the

same rate of work was continued to complete fatigue. The 3rd series was the same as the 2nd but the work as well as recovery was measured in fractions. The duration of the working period to complete fatigue averaged 25 min. with the trained porters and only 6.4 min. with the untrained mental workers. With the work of 1200 kilogrammeters the O debt was 31.5% of the total O required for the work with the porters and 38.1% with mental workers. In work to complete fatigue the O debt was 9.9 and 37.8% of the O requirement in the 2 groups respectively. The duration of recovery with 1200 kilogrammeters was 15 min. with porters and 26 min. with mental workers. With work to complete fatigue the recovery period was 35 and 45 min. respectively and in relation to the period of work was 1.97 and 7.50 times as long. A man without training spent 23% more energy in the work of 1200 kilogrammeters and 54% more in work to complete fatigue than did the porters. The efficiency fell off with the untrained worker whereas with the trained worker the efficiency remained unaltered or increased when the work was carried to complete fatigue. The R.Q. rose during the work after a preliminary fall with the porters to a higher level, which however did not reach unity, and remained at this level during the work. With untrained subjects the R.Q. continued to rise during the entire period of work going occasionally above 1.0 when the time of work was long. During recovery the R.Q. rose in the first min. over 1.0 and with the untrained workers went as high as 2.0. The R.Q. then fell to below the rest value and continued so even when the O was reestablished at the original level. The total R.Q. of the work and recovery period and also the R.Q. of the excess metabolism was higher than that in the resting condition and with mental workers higher than with load carriers. It rose with the latter when the work lasted longer.—*T. M. Carpenter.*

9591. KÚTHY, A. von. Resorption, Blut NH_2-N und spezifisch dynamische Wirkung nach Fleischnahrung. *Pflüger's Arch. Ges. Physiol.* 225(4): 567-571. 1 fig. 1930.—In experiments on 18 ♂ rats a close connection appeared betwen rapidity of resorption of raw meat, increase of the NH_2-N of the blood and the increase of O-consumption or specific-dynamic action. The O-consumption rose and fell parallel with the change in NH_2-N content, furnishing evidence for the rôle of amino-acids as the cause of specific-dynamic action.

9592. LIPMANN, F., und O. MEYERHOF. Über die Reaktionsänderung des tätigen Muskels. *Biochem. Zeitschr.* 227(1-3): 84-109. 1930.—By manometric methods it has been shown that under anaerobic conditions the reaction of muscle is conditioned by the splitting of creatin phosphate on the one hand and by lactic acid production on the other; eventually there is also a slight effect due to ammonia production, esterification, etc. During the first part of the anaerobic fatigue period there is a general shift toward a greater alkalinity, which is followed by a greater acidity. In the iodoacetic acid poisoned muscle there is only the alkalinization. Both in the normal and in the poisoned muscle the chemical and the manometric methods of establishing the change in the acid-base balance agree.—*Authors' summary (transl. by M. B. Visscher).*

9593. LUCIA, P. de. Ricerche sul metabolismo dell'acido ossalico. VIII. L'eliminazione dell'acido ossalico nel digiuno e nella rialimentazione. [Studies on oxalic acid metabolism. VIII. The elimination of oxalic acid during fasting and re-alimentation.] *Boll. Soc. Ital. Biol. Sperim.* 5(4): 473-475. 1930.—Oxalic acid is eliminated even after 2 weeks of absolute fasting. During re-alimentation the oxalic acid is increased. When the diet has a rich protein content the increase is almost double that with carbohydrate diet. The increase seems to be less with a mixed diet than with unbalanced diets. —*M. Comel.*

9594. MATTERS, REGINALD FRANCIS. The influence of menstruation on gaseous metabolism. *Australian Jour. Exp. Biol. & Med. Sci.* 6(2): 133-135. 2 fig. 1929.—Observations on 2 subjects confirmed the findings of previous investigators that a rise in the basal metabolism occurs immediately before menstruation followed by a fall during the period.—*M. Dann.*

9595. MEYER, FRITZ. Über die vermehrte Produktion spezifisch-dynamischer Wärme im Anschluss an muskuläre Höchstleistungen. (Nach Versuchen am Hunde.) *Arbeitsphysiologie* 2(5): 372-386. 2 fig. 1930.—The measurements were made by means of a Benedict respiration apparatus. The effect of the ingestion of 500 gm. of raw beef containing 3% N and 2.4% fat was to increase the metabolism 47 calories over that found at rest with no food. After an 8.5 hr. run of 35 km. at 9° 30′ grade, the same amount of meat resulted in an increase in metabolism of 72% over that found with the same amount of meat after rest. The author's interpretation is that the greater specific dynamic action after work was due to the extra chemical work which the organism performed in order to transform the ingested protein into materials suitable for the metabolism of the muscles.—*T. M. Carpenter.*

9596. MASSONOV, DIMITRY. Über den Einfluss der Oxydationsprozesse auf die Verteilung von Vitalfarbstoffen in der Zelle. *Zeitschr. Wiss. Biol. Abt. B, Zeitschr. Zellforsch. u. Mikrosk. Anat.* 11(1): 179-217. 1 pl., 15 fig. 1930.—Frog intestine was used for all experiments recorded. Duodenal epithelial cells of a summer frog contain numerous protein granules which have become infiltrated with inorganic ferrous and ferric salts. Other parts of the intestine (except the rectum) do not have any permanent inclusions. The mucous membrane of all regions contains numbers of macrophages, which are packed with Fe-containing granules. The acid and basic dyes (neutral red, methylen blue, Janus green acid fuchsin, trypan blue) could be made to accumulate in the cells in the same way. In the epithelial cells they form new structures; in the macrophages on the other hand they stain preformed granules. If a frog is placed in an atmosphere of H the intestinal mucous membrane assumes a pH of 12-13, this is shown by a reddening of the Janus green particles and a partial fading of the methylen blue. When O is lacking vital stains are differently distributed than under normal conditions. Normally the dye is condensed in granules in the cytoplasm, leaving the nucleus unstained; the phagocytic inclusions are strongly stained. When O is lacking no dye granules are formed; the cytoplasm and phagocytic inclusions are diffusely and the nucleus deeply stained. This stain distribution may be fixed by formalin. Vital staining of the nucleus is a reversible reaction; when O is added the color disappears and cytoplasmic granule formation begins. Cells whose nuclei have been vitally stained do not lose their function; they are able to absorb fat. The raising of permeability of the nuclear membrane in a H atmosphere cannot be explained by a change of its properties. Nuclear staining is associated with a reversible gel formation. The results given suggest a possible "physiological" and "physical" division of material in the cell. The former is present during periods of energy expenditure and O abundance; when O is lacking a physical division of cell material takes place. Energy is required for the formation of heterogeneous plasma granules, but no energy is required to maintain this condition. The cytoplasm-nucleus heterogeneity, however, requires energy of maintenance. Energy which serves to form and maintain heterogeneity in a cell may be designated as "energy of distribution."—*Author's summary (transl. by F. R. Hayes).*

9597. OKSIUSOW, W. Über den Einfluss der Sauerstoffeinatmung auf die Nahrungsausnutzung bei Tuberkulosekranken in Sanatorien. Vorläufige Mitteilung. *Zeitschr. Tuberk.* 57(4): 240-252. 1930.—In 1928, 437 patients under O treatment were observed, and in 1929, 361; the weight curves and other data are given for 33. Oksiusow concludes: The inhalation of pure O through a respirator in the suggested dose according to the method we have worked out increases in many in-

stances the assimilation of food by tuberculous patients who suffer from undernutrition and who can not assimilate the often unnecessarily large sanatorium diet. Such a method of treatment should be continued during a 2-3 week period of observation of the patient and certainly with those who are not gaining weight under the sanatorium régime. The treatment with O inhalations is not technically difficult and can readily be carried out in any sanatorium. By such a procedure for fighting the undernutrition of the tuberculosis patient in the sanatorium, the conviction of the patient can be strengthened that the diet in the sanatorium is to be considered a therapeutic measure. It is felt that if instead of the enormously large ration which all patients in the sanatorium are given without choice, the question of the alteration of the diet in the sense of its content of fat, carbohydrate and protein according to the assimilability of each were considered, the allowance of food might be decreased. Probably the inhaled O stimulates the islet-apparatus so that the patient rapidly develops a hypoglycemia. This causes an increase in the function of the islet-apparatus. The variations of the blood sugar value of tuberculosis patients are within normal limits. It would be desirable to test these observations on a larger number of sanatorium patients. —*Author's conclusions (transl. by G. T. Lewis).*

9598. PRIKLADOWIZKY, S., und A. APOLLONOW. Muskeltätigkeit und chemische Blutveränderungen. II. Mitteilung: Gesamte CO_2 und Zucker im Blute (reduzierte Stoffe). *Arbeitsphysiologie* 3(4): 322-329. 2 fig. 1930.—Four adult dogs were caused to run, 6-18 hrs. after previous feeding, 6.6 kms. on a treadmill in 30 min. Blood samples were taken from the femoral artery before and 1, 30, and 90 min. after the run. Control experiments at rest resulted in no changes in the blood CO_2 and sugars. There was a drop of total CO_2 and a rise in the blood sugar at 1 min. after the run. The sugar rose from 100 mgm. per 100 cc. of blood before the run to 129 mgm. maximum at 1 min. Both total CO_2 and sugar returned to nearly normal at 90 min. after the run. The injection of 250 cc. of isotonic NaCl solution produced no noticeable changes in either total CO_2 or sugar. The injection of 10 cc. of lactic acid in 250 cc. of isotonic NaCl solution and of 250 cc. of 2% HCl produced even more marked lowering of the total CO_2 and rise in sugar than did the muscular activity. One of the essential factors in the production of hyperglycemia as the result of strenuous muscular activity of short duration is the decrease in the alkalinity of the blood due to the accumulation of acid products in the organism.—*T. M. Carpenter.*

9599. RADLOFF, ELLEN M. The oxygen pulse in athletic girls during rest and exercise. *Amer. Jour. Physiol.* 96(1): 126-131. 1931.—O consumption during rest and exercise correlated with the pulse rates in 20 athletic girls showed 2 or 3 times as much O used per systolic discharge of the heart during exercise as compared with rest. The stroke volume was distinctly increased during exercise. After 2 min. of maximal or nearly maximal exercise, the pulse returned to the resting rate by the end of 5 min. The rate of O consumption was also nearly that of the previous rest period within 5 min. A close correspondence exists between the values for the O pulse of the girls during the exercise and those of men at similar pulse rates when doing 500 kgm.-m. work per min.

9600. ROESE, H. F. Ammoniakbildung und Zuckerverbrauch des künstlich durchbluteten Säugetierdarmes. *Pflüger's Arch. Ges. Physiol.* 226(2): 190-197. 1930.—The denervated heart-lung-intestine was used, 15 experiments being made. When the bowel was empty (animal previously starved) ammonia content of perfusing blood rose steadily, exceeding 3 times its initial value at the end of 2 hrs. Amino-acid content of blood remained unchanged or rose slightly. Addition of glycocoll to blood did not accelerate the rise in NH_3 content; after introduction of glycocoll into the lumen of the bowel similar negative results were obtained, though absorption was proved by estimations of amino-acid content of blood. Urea content of blood fell steadily during course of perfusion, but not in proportion to the rise in NH_3; urea was probably retained by the bowel wall, not transformed into NH_3. The increase in NH_3 during the course of perfusion is therefore referable to bacterial activity in the lumen of the bowel. Sugar consumption was calculated by applying to observed values the known sugar consumption by the heart-lung preparation, giving average figures of 1.75 gm. dextrose per kgm. intestine per hr. for 30 min. perfusion, and 1.94 gm. per kgm. per hr. at 90 min., the error probably not exceeding 10%. Applying these to figures for O consumption it is calculated that at least 80% of the glucose presented to the bowel wall becomes available for other uses.—*C. F. Schmidt.*

9601. ROSENBLUM, D. E. Fehler der respiratorischen Gaswechselmethode bei dosierter Muskelarbeit. *Zeitschr. Klin. Med.* 111(2): 191-197. 1929.—A human subject lifted a 5 kgm. weight from the shoulders to a height of 0.55 meters, 20 times per min. during an experimental period of 3 min. O consumption was measured during the work and recovery periods. From 7 to 10 days' training were required to bring the energy requirement for this work down to a constant minimum. Failure of other investigators to include training effects and data of recovery periods has lead to errors in indirect calorimetry.—*W. N. Berg.*

9602. ROSENBLUM, D. E. Zur Frage der Beständigkeit des Grundumsatzes. *Zeitschr. Klin. Med.* 111(2): 198-204. 1929.—Basal metabolism was determined in 3 young men from 5 to 8 times in 45 days and found not to vary by as much as 10% from the usual tables.—*L. Irving.*

9603. RUOTSALAINEN, ARMAS. Zur Kenntnis der Kohlensäureproduktion bei finnischen Mädchen im Schulalter. *Skand. Arch. Physiol.* 60(5/6): 225-243. 1930.—CO_2 production of 150 girls, while sitting and reading, was determined. In girls 9-19 yrs. old, CO_2 production increased with age. The averages, per person, per 2 hrs., were for 9 yr. olds, 10.7 gm., and for 18 yr. olds, 15.1 gm. CO_2. Corresponding values obtained by Olin were 11.6 and 17.6 gm. CO_2 production per kgm. body weight, per 2 hrs., was at 9 yrs., 0.39 gm. and at 18 yrs., 0.26 gm. Per sq. m. body surface, per 2 hrs., the CO_2 production was at 9 yrs., 9.76 gm.; and at 18 yrs., 7.71 gm. Corresponding figures by Olin on boys are a trifle higher.—*Author's summary (transl. by W. N. Berg).*

9604. [SHATERNIKOV, M. N., O. P. MOLCHANOVA and M. TH. TOMME.] ШАТЕРНИКОВ, М. Н., О. П. МОЛЧАНОВА и М. Ф. ТОММЕ. К вопросу о дыхании жировой ткани. [Respiration of fatty tissue.] [German summary.] *Jour. Biol. et Méd. Exp. [Moscow]* 7(18): 375-384. 1927.—See B. A. 3(4/6): Entry 5910.

9605. SHATTUCK, GEORGE C., and FRANCIS G. BENEDICT. Further studies on the basal metabolism of Maya Indians in Yucatan. *Amer. Jour. Physiol.* 96(3): 518-528. 1931.—During a medical expedition to Yucatan in 1930 the basal metabolism was measured of a group of 26 ♂ Mayas at Chichen Itzá. These observations were made to supplement the earlier measurements on Mayas by Williams in 1927, and in 9 instances the same subjects were studied that had been measured during the earlier expedition. The respiration apparatus employed was especially devised for racial studies in the field. These 2 separate expeditions have both presented data that suggest that the Mayas may have a high basal metabolism associated with low heart rate and low blood pressure. In those cases in which observations were repeated on the same subject there was a general, although not invariable, tendency for the metabolism to be slightly lower in the 2nd measurement. This fact suggests that by repeated observations a metabolism figure might be reached that could not be considered abnormally high, although evidence in general shows these people to be quiet, phlegmatic, and nontemperamental. There was no indication, so far as the

pulse rate was concerned, of psychic disturbance.—*Authors' summary.*

9606. SILANDER, O., und H. VIRI. Der Stoffwechsel beim Barrenturnen. *Skand. Arch. Physiol.* 60(5/6): 247-250. 1930.—The subjects were all young men of 20 to 22 yrs., first yr. students in the gymnastic institute of the university. Subjects I and II were particularly good, III, IV and V were good gymnasts. The average figure was 566 calories per hr. The highest value was 697 calories (subject I); the lowest value 480 calories (subject II); the variation of the results was, therefore, considerable. In the same subject the values varied, e.g. subject I, one observation 697 calories, and another 522, a difference of 175 calories. Since the average weight of the subjects was relatively small (65.0 kgm.), the increase of the metabolism was extraordinarily great. The metabolism at complete rest was 1 calorie per kgm.-hour and rose during exercise upon the parallel bars to 8.7 calories per kgm.-hour. The highest value was 10.6 calories and the lowest 7.5 calories, a difference of 3.1 calories. The values in the same individual (subject I) also varied considerably, the range in several experiments being 2.6 calories.—*Author's summary (transl. by I. I. Lemann).*

9607. SOKHEY, S. S. Normal basal metabolism of Indians. *Far East. Assoc. Trop. Med. Trans. 7th Cong. Brit. India* 3: 321. 1928[1928].

9608. WANG, CHI CHE, SOLOMON STROUSE, and EDITH SMITH. The metabolism of obesity. VII. The after-effect of muscular exercise on the production of basal heat. *Arch. Internal Med.* 46(1): 40-45. 1930.—A total of 41 experiments consisting of 4 tests each were conducted on 35 women, 13 of whom were obese, 15 normal and 7 underweight. The average values for the production of heat 15 min. after muscular exercise were +6.5, +3.1 and +6.8% above the basal value for the obese, normal and underweight subjects, respectively. The corresponding values 30 min. after the exercise were +0.9 and +0.8 and −0.1%. The lowered production of heat after exercise was accompanied by a lowered respiratory quotient. Based on the authors' observations, a 30 min. rest is an adequate fore-period in measuring basal heat production.—*Authors' summary.*

WATER BALANCE

9609. BOSCH, OSKAR. Über den Einfluss der Nahrung auf Wasserhaushalt und Wasserausscheidung im Säuglingsalter. *Zeitschr. Kinderheilk.* 50(1): 96-112. 1930.—Healthy ♂ infants (number not stated) in the 4th and 5th month, weighing about 5 kgm. were placed first on a normal diet, then on one of high H_2O content, and one of low. When no food was given renal and extrarenal excretions were reduced; when the diet was high in H_2O, extrarenal and renal excretions were increased; when low the extrarenal excretion was increased and renal decreased; the highest renal excretion occurred at night. Carbohydrates led first to a reduction in excretion by both routes, followed by an increase which resembled that following the high water diet. Protein led to less diuresis and increased extrarenal outgo, resembling the dehydration type of excretion. Since this type was never attained with a carbohydrate or a normal diet it would appear that the dehydration form of exc. is due to the protein content of the food. Partial replacement of protein by sugar mitigated the specific protein reaction.

9610. CALDWELL, G. T. Studies in water metabolism of the cat. The influence of dehydration on blood concentration, thermoregulation, respiratory exchange, and metabolic water production. *Physiol. Zool.* 4(2): 324-359. 1 fig. 1931.—Cats acclimated to the semi-arid conditions of Tucson, Arizona, were dehydrated by water deprivation in circulating air from which all moisture had been removed. Acute starvation was prevented by feeding lean, cooked meat at 12 hr. intervals. Determinations were made of all water received by the animals from food and all water given up by the animals. The average water intake-output ratio was 1: 4.78 and the negative water balance averaged 26.8% of the original body weight. Dehydration increased the blood concentration 45% for all experiments, and an increase of 75% was recorded without fatal results. The variations in body temperature of the dehydrated cats did not exceed the variations of control cats kept at room temperature; there was no indication that a reduction of free water results in an increase in body temperature. At certain stages of dehydration the average respiratory exchange of the cats was increased 30%. The minimum metabolic water production averaged 5.94 gm. per kgm. per day. Increased severity of dehydration had no appreciable effect on metabolic water production.—*Author (courtesy Wistar Bibl. Serv.).*

9611. JACKSON, C. M., and V. D. E. SMITH. The effects of deficient water-intake on the growth of the rat. *Amer. Jour. Physiol.* 97(1): 146-153. 1931.—Of 12 young rats 23-47 days old (1 litter of 5 ♀ albinos, 1 of 4 ♂ hybrids and 1 of 3 ♀ hybrids), 2 were used as normal controls, receiving unrestricted food and water, and remaining active and healthy throughout the 223 days of experiment. The 7 experimental rats were held at nearly constant body weight for several mos. by a restricted water intake, food being unrestricted. The water requirements decreased up to the 2nd or 3rd mo. of the experiments, after which they tended to increase slightly; the food consumption was roughly parallel with the water intake. These rats became emaciated and the organs became dehydrated and dystrophic. The remaining 3 rats were used as "restricted food controls," being given the same amount of food as that voluntarily consumed by the corresponding experimental rats, but unrestricted water; they gained 33-98% in weight; they became emaciated and dehydrated, but to a less degree than the corresponding test rats, thus demonstrating the importance in growth of the water intake, independent of the food consumption.

CARBOHYDRATE METABOLISM

9612. ARNOLDI, WALTER. Der Glykogengehalt der Leber nach Zufuhr einer Glauberquelle. *Zeitschr. Ges. Exp. Med.* 73(3/4): 452-457. 1930.—Of 13 rabbits, 7, and of 20 rats, 11 received Na_2SO_4 water, while the remaining rabbits and rats received plain water. The glycogen content of the liver tended to rise in both rabbits and rats on Na_2SO_4 water, the difference between experimental animals and controls increasing with continued treatment, and also with feeding to the experimental animals of a carbohydrate-rich (instead of a protein and fat-rich) diet.

9613. BAUKE, E.-E. Wird Milchzucker von der Haut resorbiert? (Ein Beitrag zur Frage der perkutanen Ernährung.) *Deutsche Med. Wochenschr.* 56(44): 1869-1870. 1930.—Stejskal has reported resorption of lactose through the skin, evidenced by demonstration of mucic acid in the urine after rubbing a lactose salve on the skin. Bauke was unable to find mucic acid in the urine of any subject (presumably human, number not stated) after application of 160 gm. lactose to the skin as salve. After subcutaneous injection of 5 cc. of a 20% lactose solution, however, the lactose and mucic acid resulting from the oxidation of lactose were demonstrated in the urine. Bauke concludes that the skin is altogether unadapted to the resorption of nutrient material.

9614. BLOCH, JOSEF, und MARIA WEISZ. Reflex- oder Resorptions-hyperglykämie? *Zeitschr. Ges. Exp. Med.* 69(3/4): 453-461. 1930.—The rise in blood sugar after oral administration of galactose is due at first to dextrose which is discharged from the liver as a result of reflex action. Later the hyperglycemia is due in part to the galactose absorbed. When galactose enters the blood, the discharge of dextrose from the liver decreases so that the dextrose level with galactosemia becomes lower than in the fasting state. With slight liver damage there may be increased discharge of dextrose into the blood. Galactosemia begins earlier and reaches a higher level. If the liver is seriously damaged, the reflex discharge of dextrose may not appear because of

the low glycogen storage: there may be higher galactosuria with less hyperglycemia.—*F. N. Allan.*

9615. BORNSTEIN, SIEGBERT. Über den Einfluss der intravitalen Speicherung auf den Kohlenhydratstoffwechsel. *Zeitschr. Ges. Exp. Med.* 66(5/6): 810-816. 1929.—11 rabbits were intravenously and intraperitoneally injected with diluted india ink, using in some cases 50 injections during 17 weeks. Fasting blood sugar values after these injections and those obtained after the ingestion of glucose were compared with the corresponding values obtained with 7 uninjected controls. No appreciable differences could be observed. The blood sugar values after the administration of insulin were obtained, and here likewise there was no appreciable difference between the 2 groups, thus indicating that storage of the carbon particles did not change the capacity of the liver cells to store glycogen.—*L. G. Wesson.*

9616. CAMPANACCI, D., e C. NEGRI. Glutatione e ricambio idrocarbonato. *Ateneo Parmense* 2(3): 184-187. 1930.—In the venous blood of non-diabetics glutathion was found in the proportion of 16 mgm. %; in diabetics, 13 mgm. %. To forestall the objection that this change might be due to anemia (since all the glutathion in the blood is contained in the erythrocytes) he adds that in non-diabetic and non-anemic persons the glutathion/erythrocyte quotient in normal persons and that in diabetics are as 4:3. In necropsy on a diabetic the glutathion was found lowered in almost all the organs below the figures for non-diabetics. In 12 non-diabetic pancreases no remarkable or constant differences were found between the glutathion content of the head, body and tail of the pancreas; but in the 1 case of diabetes examined the reduction of glutathion was greater in the pancreas (1/7) than in any other organ, while the glutathion in the tail was ½ that in the head.

9617. COLWELL, A. R. **The use of constant glucose injections for the study of induced variations in carbohydrate metabolism. I. Methods and controls. II. The effects of insulin, pancreatectomy and nervous manipulations of the pancreas.** *Amer. Jour. Physiol.* 91(2): 664-678; 679-689. 1930.—I. When cats under the uniform influence of amytal anesthesia are supplied continuously with glucose by vein at constant rates, the chief characteristics of their response are as follows: (1) Abnormal glycosuria occurs on the average when the rate of supply exceeds 0.35 gm. per kgm. per hr., increases with advancing rates of supply and tends to approach but not exceed 50% of the supply with administration rates above 1.5 gm. per kgm. hr. The response of any individual animal may vary as much as 15% either way from these averages. With any individual injection rate the glycosuria is fairly constant, after a preliminary period of 2 or 3 hrs., for as long as 19 hrs. and probably longer. The blood-sugar concentration bears no such definable relation to the supply or the excretion of sugar in various animals. In any individual animal under constant conditions (especially of water supply) it is very constant. Increased muscular activity (shivering), with consequent increased consumption of sugar, is reflected ultimately as a distinct reduction in the quantity of sugar excreted. It may be concluded, therefore, that the use of these experimental conditions constitutes a reliable method for estimating the total utilization of sugar in acute experiments on unconscious animals.—II. The administration of insulin diminishes, and of epinephrine increases, the excretion of sugar resulting from the constant injection of glucose by vein. With proper dosage these responses may occur with no corresponding changes in the blood-sugar concentration. Complete removal of the pancreas causes virtually all of a constant supply of glucose to be excreted in the urine. The effect appears gradually over a period of 4-8 hrs. Under amytal anesthesia the ability to utilize glucose is not impaired by stimulation of the major splanchnic nerve after removal of the corresponding adrenal gland and section of the hepatic nerves, by denervation of the pancreas, or by bilateral vagus section.—*Author's summaries.*

9618. CORKILL, A. B., and H. P. MARKS. The effect of adrenaline on muscle glycogen. *Jour. Physiol.* 70(1): 67-85. 1930.—The spinal cat was used, with the abdominal alimentary tract and the kidneys removed, the liver being excluded from circulation though its vessels were still open to the inferior vena cava through the hepatic veins. Satisfied, in a number of control experiments, that it was possible to obtain a balance within fairly narrow limits, and that the muscle glycogen remained practically constant, while the lactic acid showed no tendency to rise, the authors proceeded to experiments in which adrenalin was administered. In 8 complete experiments the epinephrine caused a discharge from the resting muscles of glycogen, none of which appeared in the form of glucose, and only a part as lactic acid, while the sum of the lactic acid so formed and the glucose equivalent of the O used (carbohydrate accounted for) was substantially less than the total of carbohydrate disappearing from the system. In 7 of the 8 experiments the last carbohydrate unaccounted for amounted to 1.6-2.5 gm. A similar discrepancy was observed in experiments in which insulin and epinephrine acted together. It is suggested that the "lost carbohydrate" in the action of insulin on the normal animal is, in part, due to a secondary action of adrenalin.

9619. EGGLETON, M. GRACE, and C. LOVATT EVANS. Lactic acid formation and removal with change of blood reaction. *Jour. Physiol.* 70(3): 261-268. 1930.—Experiments of the authors called for data as to whether changes in the lactic acid content of the blood, consequent on its changes in H-ion concentration, could also be effected by other tissues, particularly by the muscles. Some experiments to answer this question were carried out on heart-lung preparations, 1 on the isolated perfused lung, and the remainder on isolated hind legs, perfused with oxygenated defibrinated blood at 37° C. by the Dale-Schuster pump [1928]. All the experiments were performed on the tissues of dogs. Results with the heart-lung preparation agreed with those of Anrep and Cannan, that the lactic acid content of the circulating blood could be caused to rise and fall with its pH. The experiment with isolated lungs further showed clearly that the lungs alone, even in the presence of a considerable concentration of CO_2, were not competent to reverse, or even completely to check, the accumulation of lactic acid, presumably due to glycolysis in the blood. Perfusions of hind-limb-lung preparations, however, showed that these behaved in very much the same way as the heart-lung preparation, the lactic acid rising and falling with the pH of the blood. It is presumed that the lactic acid removed by the muscles is dealt with in the same manner as that removed after exercise. The importance of avoiding over-ventilation in experiments in which variations in the lactic acid content of the blood are being studied is emphasized.

9620. EGGLETON, M. GRACE, and C. LOVATT EVANS. **The lactic acid content of the blood after muscular contraction under experimental conditions.** *Jour. Physiol.* 70(3): 269-293. 1930.—The experiments were performed on dogs and cats, some decerebrate, others anesthetized. While the average lactic acid content of superficial venous blood runs closely parallel to that of the arterial blood, yet individual samples show variations, the direction or magnitude of which cannot be foreseen or readily explained. The lactic acid content of tissues in general is somewhat less than that of the blood plasma, both at rest and during recovery from exercise, this difference being less readily observable in muscle owing to production of lactic acid during the removal and killing of the tissue. Up to about 10% difference, this could be accounted for on the basis of the higher water content of the plasma. The lactic acid content of muscles which have been given a short period of severe exercise does not come into equilibrium with that of the blood and other tissues until at least 10 min. after the end of the exercise. In the equilibrium then reached

the muscle lactate is lower than the arterial blood lactate. The lactic acid content of the venous blood returning from muscles which have been contracting remains higher than that of the arterial blood throughout recovery, while that from unexercised muscles is lower. The lungs play no part in the removal of lactic acid during recovery. The blood returning from the liver contains less lactic acid (av. 12 mgm. per 100 cc.) than the arterial blood, throughout recovery. Hence the liver removes lactic acid from the blood. Under the conditions of experiment the average rate of disappearance of lactic acid from the blood during recovery was about 2 mgm. per 100 cc. per min. In the eviscerated animal this rate was reduced only to about ½ of that value; hence the liver is not solely responsible for lactic acid removal. The lactic acid content of the blood of the resting eviscerated animal does not rise during the 4 hrs. following the evisceration. Glycogen re-synthesis occurs to a considerable extent in muscles during recovery from exercise, using amytal as anesthetic. The recovery is almost as great in the eviscerated as in the intact preparation. The source of the glycogen is uncertain. Amytal anesthesia as compared with decerebration has no depressing influence on the uptake of lactic acid by the liver during recovery from exercise, nor on the rate of disappearance of lactic acid from the blood stream in general. In the resting condition the blood sugar and lactic acid content of the blood are normal in the animal under amytal anesthesia, but abnormally high in the decerebrate preparation. Perfusion of the hind limbs of frogs with lactate led to no appreciable synthesis of glycogen by the muscles.—*Authors' summary.*

9621. **GLASS, JERZY, und IS. BEILESS. Chlorhaushalt und Kohlenhydratstoffwechsel. I. Einfluss hypertonischer Kochsalzlösung auf den Blutzucker bei Diabetes.** *Zeitschr. Ges. Exp. Med.* 73(5/6): 801-816. 1930.—The influence on the blood sugar of the intravenous and oral administration of NaCl was studied on 16 diabetic and 3 healthy persons. The injection of 20 cc. of 15-20% NaCl solution caused in diabetes a fall which was most marked in the first 2 hrs. This averaged 47 mgm. % for all the cases, which represents, when compared with the normal blood sugar, a percentile fall of 25. The hyperglycemic curve following ingestion of glucose was similarly influenced by hypertonic NaCl. In healthy persons these depressing effects of NaCl were less marked (20 mgm. %). Oral administration of 12 gm. NaCl to 2 diabetics also depressed the blood sugar and retarded the hyperglycemia due to glucose ingestion. Dilution of the blood could not be responsible for these effects on its sugar percentage, since the extent to which this could lower the latter is much less than that actually observed. Lack of correspondence between the curves for sugar and NaCl in the blood showed that osmotic phenomena were not responsible. It appears as if the hypoglycemic effect is due to the Cl-anion rather than the Na-kation.—*Authors' summary (transl. by J. J. R. Macleod).*

9622. **HAYASAKA, ENAJI. Über die Störung der Milchsäureresynthese bei nebennierenlosen Tieren.** *Tohoku Jour. Exp. Med.* 14(4): 359-384. 1929.—The lactic acid and CO_2 in the blood of 22 decapsulated rabbits, as well as their O consumption, was followed for a week after operation. Seventeen animals received injections of Ca lactate intravenously, 2 animals protracted injections of adrenin, and 3 both treatments together. Decapsulation is followed by increased lactic acid in the blood. This excess is reduced by adrenin injections. Adrenin is, therefore, an essential factor in lactic acid metabolism and the fatigue toxin in the blood of decapsulated animals is lactic acid.—*J. C. Donaldson.*

9623. **HIMWICH, H. E., and M. A. ADAMS. Studies in glandular metabolism. I. The source of the lactic acid produced on incubation of the testicle and the submaxillary gland.** *Amer. Jour. Physiol.* 91(1): 172-177. 1929.—After having observed that the percentages of total carbohydrates were approximately the same in each of 3 pairs of testicles and 4 pairs of submaxillary glands of dogs, a study was made of the effect of incubation on the glycogen, intermediary carbohydrate, and lactic acid contents of these glands. Sixteen pairs of excised testicles and 4 pairs of excised submaxillary glands were compared, 1 gland being subjected to glycolysis and the other frozen immediately upon removal. In most instances there was no change in intermediary carbohydrates following glycolysis. Experiments (5), however, offer evidence that incubation may increase the intermediary carbohydrate content to a slight though definite extent. In 5 cases a quantitative relationship was found between the decrease of glycogen and the production of lactic acid; in 9 experiments the decrease of glycogen, though marked, was less than the increase of lactic acid; in 4 other observations the glycogen, which was low in both glands, was unchanged on incubation; and in 2 cases the loss of glycogen was even greater than the increase of lactic acid. The fact that most of the observations showed a decrease of glycogen indicates that this substance is the source of part if not all of the lactic acid formed on the incubation of the testicle and the submaxillary gland.—*Authors' summary and conclusions.*

9624. **JOLLIFFE, NORMAN. The tolerance of normal subjects to levulose. Factors influencing the variations in rise in blood sugar.** *Jour. Clin. Investigation* 9(3): 363-380. 1930.—Levulose tolerance tests (91) and 12 glucose tolerance tests were performed on normal subjects under a variety of conditions. Results have been tabulated according to the fasting blood sugar level with the following conclusions: In normal subjects the maximum blood sugar following administration of 30-50 gm. (based on body weight) of levulose by mouth rarely exceeds 115 mgm. %. A rise in blood sugar to 125 mgm. % or over should be considered an abnormal response to the oral administration of levulose. In the group of convalescent subjects included in this study the levulose tolerance was the same as in the normal subjects studied. Triplicate levulose tolerance tests performed on normal subjects 7 or more days apart show no significant variation in their blood sugar curves. In normal subjects the rise in blood sugar above the fasting level following the oral administration of levulose varies inversely with the height of the fasting blood sugar level. It seems probable that there is a level of blood sugar varying from 95 to 110 mgm. %, which when exceeded stimulates the sugar storage mechanism to clear the blood rapidly of its excess sugar. A period of 10-15 min. elapses after this excitatory ceiling is reached before the sugar storage mechanism begins to cause a significant fall in blood sugar. The rise in blood sugar above this level depends upon the rapidity of absorption of the sugar administered. The rapidity with which the blood sugar falls from its peak probably depends upon the glycogen forming ability of the sugar tested.—*Author's summary and conclusions.*

9625. **KIMURA, KOTARO, und KATSUTAKA KATO. Über den zeitlichen Verlauf der Milchsäureresynthese nach Muskelarbeit.** *Tohoku Jour. Exp. Med.* 14(5/6): 569-579. 2 fig. 1930.—The time course of the resynthesis from lactic acid was studied in relation to the changes in O consumption, blood velocity and blood sugar in the dog gastrocnemius in situ, by measurements on an artery to and a vein from the muscle, before, after, and at periods of 5, 20, and 30 min. following a 5 min. period of electrical stimulation through the nerve. (See following abstract.) In 3 of 5 dogs, the O and sugar consumption, blood velocity, and lactic acid output of the muscle, which definitely rose at the end of the work period, decreased strikingly after 5 min., and again increased at the 20 min. period, while at 30 min. they tended to return to the resting values. The lactic acid output thus showed a parallelism to the oxidation curves of Barcroft and Kato. The 2 maxima in the various quantities are ascribed to effects of a transient local acidosis. The muscles of 2 of the 5 dogs used failed to exhibit the 2nd maximum.—*F. F. Heyroth.*

9626. KIMURA, KOTARO. Milchsäureumsatz im Muskel bei Nierenschädigung. *Tohoku Jour. Exp. Med.* 15 (1/2): 153-176. 1930.—The blood velocity and O consumption rate in the gastrocnemius in situ, together with the sugar and lactic acid content of an artery supplying and a vein draining it, were determined in resting normal dogs and again immediately and 30 and 60 min. after a 5 min. period of electrical stimulation at a rate of 150 contractions per minute. The observations of Hayasaki and others that stimulation increases blood velocity in, O and sugar consumption, and lactic acid output of the muscle, were confirmed. The normal state was restored in 60 min. Forty hours after bilateral nephrectomy, while both the vein and arteries showed greatly increased lactic acid, the difference between these values was subnormal. O consumption by resting muscle was increased, but blood sugar utilization was practically unaltered. Activity increased O consumption and lactic acid output of the muscle less than in normal dogs; the increase in blood velocity was very small. Increased sugar utilization in the muscle was lacking, indicating a disturbance of the carbohydrate metabolism of the muscle. Even after 60 min. the resting state was only approximated. In uremia, the lactic acid produced by muscular activity enters the circulation only slowly and the course of the resynthesis from the lactic acid is disturbed. Similar results were also obtained 60 hrs. after bilateral ureteral ligation, but at 42 hrs. after the ligation there was only a slight deviation from the normal. In nephropathy due to cantharidin, the resynthesis from lactic acid formed by muscular activity was considerably retarded. After uremic poisoning there was no outspoken deviation of intermediary lactic acid metabolism from the normal.—*F. F. Heyroth.*

9627. LISS, G., C. PI-SUÑER BAYO, und T. OSUKA. Weitere Untersuchungen über den Einfluss der Fütterung mit Hefe auf den Ernährungszustand von Muskel und Leber beim Training. *Zeitschr. Ges. Exp. Med.* 74 (5/6): 750-756. 1930.—Of 18 rats on a corn-wheat-casein-glucose diet and subjected to daily exercise, 9 received yeast and 9 did not. The dry weight of liver and muscle, the liver glycogen content, and the lactic acid and P of liver and muscle were considerably higher in the yeast-fed rats than in the controls; there was little difference between the muscle glycogen of the 2 series.

9628. LOEPER, M., et J. TONNET. Production d'acide oxalique par le Taenia. *Compt. Rend. Soc. Biol.* 106(9): 716-717. 1931.—*Taenia* (washed) were tested for glycogen, oxalic acid and glucose content before and after incubation for 24 hrs. The oxalic acid and glucose content increased while the glycogen decreased.

9629. LOEPER, M., R. DEGOS, et J. TONNET. La formation d'acide oxalique dans certaines tissus glycogènes. *Compt. Rend. Soc. Biol.* 106(9): 717-718. 1931.—Two rabbit livers were tested for oxalic acid content, incubated for about 24 hrs. with aseptic precautions, and then retested. Oxalic acid was found before treatment. It increased after incubation proportionately with increase in glucose and is due to the destruction of glycogen. Fresh calf heart gave a similar result.

9630. MASAYAMA, TATSUNORI, und OTTO RIESSER. Über die Beziehungen des Glykogens zu Kreatin und Kreatinphosphorsäure im Kaninchenmuskel. *Biochem. Zeitschr.* 234(1/4): 323-340. 1931.—The ratio phosphagen: glycogen in per cent was the same for the identical animal (rabbit) in different skeletal muscles (white and red), although the absolute values might differ considerably. If within a few days the absolute values of glycogen and phosphagen changed, the quotient remained unaltered. Isolated muscles in an O-containing Ringer's solution lost considerable phosphagen and glycogen when irritated till fatigued. Here, too, the quotient phosphagen: glycogen remained the same. Without addition of O, the isolated muscles decreased their phosphagen content more than the glycogen, lowering the quotient. Fasting animals, especially when treated with epinephrine, lost more glycogen than phosphagen, thus increasing the quotient. Tetrahydro-β-naphthylamine and caffeine caused, within a short period, a great loss of glycogen, while phosphagen underwent little or no decrease. Always the creatine content of the muscles was raised. Under the action of the above mentioned toxins the per cent of total creatine which was bound to phosphoric acid decreased more or less markedly. On the average, in normal muscles 55% of creatin is bound to phosphoric acid; in the muscles of intoxicated animals, 31%.—*From author's summary (transl.).*

9631. MISCHNAT, H., H. SCHOENEN, und P. JUNKERSDORF. Untersuchungen über die chemische Zusammensetzung der Lunge; ein Beitrag zur Stoffwechselphysiologie der Lunge. *Pflüger's Arch. Ges. Physiol.* 226 (3): 448-463. 1930.—Analyses were made of lungs from dogs kept either with constant diet, varying diet, starved or treated with phloridzin, phloridzin and insulin or with adrenalin. Estimations were made of the relative weight of the lungs in proportion to body weight, and of water, glycogen, fat, total N, total P, lipid P and Ca content. The weight of the lungs was between 0.82 and 1.05% of the body weight except with starvation of long duration when it rose (highest 1.93%). The weight of the right lung was some 24% greater than that of the left. Water content was between 77.31 and 79.77% except after long starvation. Glycogen content was very low—mean 0.137%. The highest averages were seen in starved phloridzinised dogs 0.176% and in starved phloridzin-insulin animals 0.174%; the lowest values 0.09% after adrenalin. The greatest variations were seen in the starved animals. The fat content was on the average 12.27% (excluding starved animals); a value of 4.71% was obtained after starvation for 43 days. In animals fattened on carbohydrates the glycogen content of the lungs was somewhat raised, the fat content somewhat lowered. The total protein content was about 12%. Total P estimated as P_2O_5 was 0.777% and lipid P 0.105%. Calcium content was on the average 0.042%.—*H. C Bazett.*

9632. MIYAMOTO, DENZABURO. Über den Einfluss wiederholter Zufuhr überschüssiger Glucose auf den N-Stoffwechsel, die Zuckertoleranz und die Zuckerausscheidungsschwelle. *Japanese Jour. Med. Sci. IV. Pharmacol. Trans.* 4(3): 249-259. 1930.—Repeated daily oral administration of excess of glucose to rabbits causes a decrease in N excretion and an increase in sugar tolerance. The process of deamination as well as that of urea formation is also disturbed. When the daily excess of glucose is given by subcutaneous or intravenous injection, the tolerance for sugar is at first increased but then decreases, the sugar threshold becoming gradually lower. Later still, the sugar tolerance again rises until finally the animal dies. Histological changes in the islets of Langerhans (hyperplasia) are described after the excessive sugar administration.—*J. J. R. Macleod.*

9633. NÉMETH, L. Untersuchungen über die Wirkung der Brenztraubensäure auf die Drosophila melanogaster. *Biochem. Zeitschr.* 231(4/6): 385-392. 1931.—Pyroracemic acid on sugar-free agar in the presence of yeast was an adequate source of food and energy, since the entire life cycle was completed in the plates. The animals soon died on agar without sugar or pyroracemic acid. Similar experiments with chemical combinations chemically and biologically related to pyroracemic acid and the products of intermediary carbohydrate metabolism (acetic, tartaric, formic, lactic, and succinic acids) did not give comparable results. Pyroracemic acid is thus a specific source of food and energy for *D. melanogaster.*

9634. NIELSEN, NIELS A. Die Wirkung des Insulins auf den Glykogengehalt der perfundierten Kaninchenleber. *Biochem. Zeitschr.* 230(4/6): 259-268. 1931.—In perfusion of rabbit livers with defibrinated blood without insulin, a gradual decrease in the amt. of glucose in the perfusion blood occurred, with a corresponding deposition of glycogen in the liver. After perfusion the glycogen was very unevenly distributed. The addition of ½-20 international units of insulin produced a rise of the glucose in the perfusion blood and a decrease of glyco-

gen in the liver. No action occurred with less than this amt.

9635. **OCHIAI, KUNITARO. Über das Kernglykogen im Herzmuskel von Bufo vulgaris japonicus.** *Nagoya Jour. Med. Sci.* 5(2): 125-147. 1 fig. 1931.—Among 40 toads nuclear glycogen was found in the form of distinct granules in the cardiac muscles of 31, both in the ventricular and the auricular walls, but somewhat more frequently and abundantly in the former. It was found most frequently in summer; the other seasons presented no difference as to frequency. Injection of insulin had no influence on the presence of nuclear glycogen in cardiac muscle. The chromatin and nucleoli disappeared, in the glycogen-containing nucleus, only from the sites of the glycogen; the remainder of the nucleus showed no abnormal changes. No relation could be traced between the presence of nuclear glycogen and the fat content of cardiac muscle. Glycogen was as plentiful in the sarcoplasm of cardiac muscle fibers the nuclei of which contained distinct granules of glycogen as it was in other fibers. The nuclear glycogen in these toads was apparently formed from protein bodies by some chemical non-pathologic process the biologic significance of which remains to be explained.—*Author's summary (transl.)*.

9636. **SCHEIFF, W. Untersuchungen über die chemische Zusammensetzung der verschiedenen Leberlappen. Ein Beitrag zur Stoffwechselphysiologie der Leber.** *Pflüger's Arch. Ges. Physiol.* 226(4/5): 481-499. 1931.—The individual lobes of the liver in dogs, rabbits, and turtles, were studied in respect to their contents of water, glycogen, fat, total N and rest N. The different lobes of the same liver as well as the same lobes of different livers show considerable irregular variations in composition. The periphery of a lobe was generally slightly higher in glycogen than the interior. These variations suggest that doubt may be raised concerning conclusions drawn from analyses of portions of the liver in perfusion experiments. The variation in composition of the different lobes is thought to be due to functional variations in the lobes brought about by differences in the composition of the blood entering them.—*D. Wright Wilson.*

9637. **SCOZ, G. Ricerche sul metabolismo dei grassi. VII. Contenuto in glicogeno del tessuto adiposo dei ratti in varie condizioni di alimentazione. [Glycogen content of adipose tissue of rats in various conditions of alimentation.]** *Boll. Soc. Ital. Biol. Sperim.* 5(6): 1037. 1930.—As formerly shown in dogs, in rats no marked difference is present as to the glycogen content of subcutaneous adipose tissue and of omentum. Re-alimentation after fasting is followed by a marked increase of glycogen—*M. Comel.*

9638. **TSUKADA, S. Über den Zuckergehalt in Haut und Blut bei normal gefütterten Kaninchen.** [In Japanese, with German summary, p. 58-59.] *Japanese Jour. Dermatol. and Urol.* 30(6): 561-568. 1 pl. 1930.—The skin sugar content in 25 ♂ and 20 ♀ white rabbits on ordinary diet was calculated from 9 pieces of skin simultaneously snipped from the back of each; samples of blood, 6 in all, were taken from the ear vein of each rabbit at 2-hr. intervals. No sexual differences were found. The values obtained were: skin, min. 73-164 mgm. %, av. 133 mgm. %; blood, 84-139 mgm. %, av. 105 mgm. %; the averages are fairly close to those obtained by Urbach. Apparently he is right in declaring that the skin plays an important part in carbohydrate metabolism.—*From author's summary (transl.)*.

9639. **WIERZUCHOWSKI, M. [et al.]. Intermediärer Kohlenhydratstoffwechsel. VI. M. WIERZUCHOWSKI, W. PIESKOW, und E. OWSIANY. Zuckerassimilation, Phosphor- und Wasserstoffwechsel bei intravenöser Dauerinjektion der Glykose, Fructose und Galaktose. VII. M. WIERZUCHOWSKI, und M. ŁANIEWSKI. Milchsäureproduktion bei intravenöser Dauerinjektion der Glykose, Fructose und Galaktose. VIII. M. WIERZUCHOWSKI. Respiratorischer Gaswechsel der Glykose, Fructose und Galaktose bei ihrer intravenösen Injektion.** *Biochem. Zeitschr.* 230(1/3): 146-172; 173-186; 187-224. 1931.—VI. The total reduction in deproteinized blood ("blood sugar") of 3 well-nourished, fasting dogs was 91-104 mgm. %, of which 54-67 mgm. % was glucose, and 34-40 mgm. % residual reduction. In continuous glucose injection for 3 hrs. (2 gm. an hr.), the amt. of glucose in the blood rose during the 1st hr. to about 300 mgm. %; in the 2nd hr. it sank. Such a 2-phase reaction was found with no other hexose injected. Two hrs. after the injection ended, the glucose sank below its original value and only traces were present in the urine. During the experiment 10.50% of the quantity injected was excreted in the urine, the glycosuria and the glycemia curve showing the 2 phases. With injection of fructose, the concentration rose from hr. to hr. It disappeared from the urine 2 hrs. after injection ceased; 10.3% was excreted. The galactosemia curve rose rapidly during injection, attaining 800 mgm. %. Only 9 hrs. after injection were blood and sugar free; 69.6% was excreted in the urine. The 2-phase glucose reaction disappeared when insulin was given; assimilation was slightly increased. Fructose assimilation was not increased. Galactose with insulin disappeared from the blood more rapidly, and only 58.0% was excreted. During fructose or galactose injections the glucosemia did not increase. When insulin was also injected the glucose concentration of the blood decreased; the simultaneous fructosemia or galactosemia increased. The residual reduction was unchanged during the injection of glucose or fructose. Only that sugar which was being injected showed an increase in the blood. There was apparently no relation between the blood and urine phosphates and the sugar metabolism. The blood was most diluted with galactose, least with fructose. Insulin had an anhydremic action in those cases where it increased assimilation. The amt. of urine was related to the amt. of hexose excreted.—VII. The lactic acid content of the blood in fasting dogs was 7-25 mgm. %; the amt. excreted in the urine hourly was 1.4-5.1 mgm. With injection of each of the 3 sugars, as in VI, the lactic acid curves were characteristic, and the excretion in the urine was similar. Under the influence of insulin, excretion was greater with all 3 sugars. Lactic acid production was as high during sugar injection as during heavy, muscular work. There was also agreement between the drop in the CO_2-combining power of the blood and the increase in lactic acid concentration.—VIII. The av. increase of respiratory, non-protein, quotients during the sugar injection without insulin was: glucose 0.23, fructose 0.24, galactose 0.13; with insulin it was 0.26, 0.30, and 0.18 respectively. The specific dynamic action was 9.7, 13.8 and 17.3% respectively of the caloric content of the assimilated sugar. The greatest increase in heat occurred during the 2nd and 3rd hrs. of injection, being 51, 63 and 32% over basal. Divided into hyperglycemic periods, with insulin the caloric production rose 21, 38, and 23% in comparison to similar periods without insulin, the greatest increases being 57, 85 and 32%. In the hypoglycemic periods in the 7th and 8th hrs. of the experiment, the heat was increased 36%. One half gm. per kgm. was the most sugar an animal could oxidize in an hr. Of the total amt. assimilated, 34% of the glucose, 41% of the fructose, and 56% of the galactose underwent oxidation. Carbohydrate calories furnished the source of specific dynamic increase in heat, giving up to 32% in glucose experiments, 41 in fructose, and 37 in galactose. When 1 mol sugar was oxidized 235 cal. were obtained in each. The oxidation quotient was 3.04 for glucose, 2.48 for fructose, and 1.82 for galactose. On the basis of the first 4 hrs. it was 3.98 for all glucose and fructose experiments. In controls with physiological saline the increase was only 1.87 kgm.-cal. above the average basal metabolism. The heat and the increase in the respiratory quotient during the 2nd and 3rd hrs. were inversely proportional to the concentration of the hexoses injected into the blood. Thus the period of excess sugar in the tissue juices and the specific dynamic action were in general parallel. In many instances the heat curve and the lactic acid in the blood were not

parallel. The specific dynamic action and the oxidation seemed to be greater, the more lactic acid formed.—*From authors' summaries (transl.).*

FAT METABOLISM

9640. **ANDRÉ, EMILE, et HENRI CANAL.** Contribution à l'étude des huiles d'animaux marins. Recherches sur l'huile du Centrophore granuleux (Centrophorus granulosus Müller et Henlé). *Bull. des Trav. Publ. Stat. Agric. et Pêche de Castiglione* 1928(2): 47-64. 1928.—The oils of the egg and of the livers of the fetal, young and adult animals were analysed. The unsaponifiable portion of the oil increases gradually from 50% in the egg to 91% in the liver of dog-fish adults and is composed of highly unsaturated hydrocarbons. Study shows these hydrocarbons to have their origin from glycerides containing fatty acids of the clupanodonic series. The alcohols of the cholesterol group appear to be an intermediate stage as they are much more abundant when the glycerides are present in greater quantity. This agrees with previous studies made upon the livers of young and adult peregrine falcon. This biological reaction is reversed when the oil passed from the liver of the gravid female to the egg.—*Authors' summary and conclusions (transl. by A. G. Mulder).*

9641. **BECKMANN, KURT.** Leber und Mineralhaushalt. V. Die Wasser- und Ionenabgabe der Leber an das Blut bei Blockierung des Retikuloendothels und nach Cholesterinfütterung. *Zeitschr. Ges. Exp. Med.* 67(1/2): 175-186. 1929.—Rabbits were injected with collargol on several days before the experiment; this compound accumulated chiefly in the stellate cells of Kupffer without observable functional damage to the liver. Cholesterol was fed in sunflower seed oil for 4 mos. before the experiment; fat then accumulated in the Kupffer cells without cirrhosis. The concentrations of protein, water, 3 cations and 3 anions were determined in serum drawn before, and 2 min., 10 min., and 15 or 20 min. after, the injection of 20 cc. of an isotonic solution of some one salt into the portal vein. As compared with control rabbits, no differences in blood dilution were found, but various ions appeared to exchange with the liver more or less quickly. Considerable anion deficits were set up in the serum. It is concluded that the reticuloendothelium, as well as the liver parenchyma, is concerned in the regulation of ionic concentrations by the liver.—*E. F. Adolph.*

9642. **BEUMER, H., und F. HEPNER.** Zur Frage der Herkunft des Ergosterins im Organismus. *Biochem. Zeitschr.* 222(1/3): 204-210. 1930.—The results here given are based on "repeated" studies on rats, guinea-pigs and mice. Experiments on 24 mice are tabulated, and a protocol of an experiment on 5 mice given. The animals were fed ergosterol in one or another of 3 ways: dissolved in oil, melted with cholesterol and dissolved in oil, or dissolved in oil with cholesterol and cholic acid. After being fed with cholesterol in one of these forms for 6 days, the animals were killed. The ergosterol in the body was estimated chemically and biologically. The chemical method, based on the fact that irradiated ergosterol loses the power to precipitate digitonin, was carried out by separating the animal extract into 2 portions, one of which was exposed to strong sunlight, the other not, and both then tested against digitonin, the differences in precipitability, affording a basis for estimating the ergosterol content. The results indicated the resorption of ½ the part of the combined ergosterol, but less than 1/300 of the ergosterol fed alone. Analysis of the feces by the difference method showed excretion of large amounts of unresorbed ergosterol though not enough to account for the difference between ingested and resorbed ergosterol, a fact which may, in the authors' opinion, be accounted for either by loss of feces or destruction of ergosterol. This method was not, however, sufficiently delicate to exclude the possibility of the resorption of exceedingly small amounts. For this purpose the extract of an ergosterol fed animal was activated by irradiation and fed to a rachitic rat, in quantity such that, assuming the resorption of 1 mgm. of ergosterol, an anti-rachitic action must have been seen in the rat; no such action was ever seen in repeated experiments. The question remains open whether ergosterol is drawn from the nutrition of the body or is synthesized within it. Until this is answered, Beumer and Hepner believe, the discussion as to whether rachitis is an avitaminosis or not is an empty argument over words.

9644. **BLOOR, W. R., and RUTH H. SNIDER.** The neutral fat of beef liver and other tissues. *Jour. Biol. Chem.* 87(2): 399-413. 1930.—The neutral fat of beef liver was found to be considerably more unsaturated than the fat of the fat depots or of the other organs examined. This finding is in agreement with that of Kennaway and Leathes and supports Leathes' conception of the liver as a desaturating organ for the fatty acids. However, the possibility cannot be excluded that the presence of more highly unsaturated fats in this organ may be due to selection of these substances from the blood, possibly as part of the protective function of the liver. The percentage of fat in most of the livers examined was variable and small both absolutely and in relation to the phospholipid content, and for this reason the phospholipid to fat ratio was high (average about 86: 14). Occasional high fat values in normal samples of all tissues emphasize the normal variability of the fat of the liver and other organs. While the fat content of the organs was variable the phospholipid content was quite constant for each organ and characteristic of the organ. The I number of the liver phospholipid was lower than that of the other organs examined.—*Authors' summary.*

9645. **BOUCKAERT, JEAN J., and E. SOLOMON.** Beta-tetra-hydro-naphtylamine hyperthermia and fat metabolism. *Amer. Jour. Physiol.* 95(2): 417-421. 1930.—No constant relation was discovered between the fat content of the liver and the hyperthermia induced by injection of β-tetra-hydro-naphtylamine in dogs. In some cases the fat content is increased, in other cases it is decreased and in some experiments it does not change. The exchanges of fat between the liver and the tissues thus seem to be independent of the hyperthermic reaction of the animal. Consequently the animals which are poor in glycogen do not use up the stored liver fat to increase their caloric production during the β-tetra-hydro-naphtylamine hyperthermia. It is probable that the increase of metabolism in this condition is due to using up of the protein after the carbohydrates have been depleted.

9646. **BROWN, J. B., and A. L. RAWLINS.** Effect of feeding whale oil on the depot fat of the white rat. *Proc. Soc. Exper. Biol. & Med.* 26(8): 704-705, 1926.—Rats were fed on diets containing 10% and 20% of whale oil for from 2 to 10 weeks. Equilibrium between the food fat and the depot fat is established within 4 to 6 weeks. The highly unsaturated fatty acids of whale oil, including acids with 4, 5, and 6 double bonds, are apparently deposited as such in the depots. When once stored, these highly unsaturated fatty acids are removed only slowly.

9647. **BROWN, J. B., and S. G. MORRIS.** The effect of varying amounts of menhaden oil in the diet on the composition of the body fat of the white rat. The storage of highly unsaturated fatty acids. *Jour. Nutrition* 2(5): 509-515. 1930.—The characteristic highly unsaturated fatty acids of menhaden oil are deposited in the body fat of the white rat when these acids are included in the diet. Diets containing 5-30% of menhaden oil resulted in a deposition of highly unsaturated acids from 9.7-17.2%. In the diets studied, the content of highly unsaturated acids of the depot fat was always higher than that of the diet. The highly unsaturated acids deposited were more unsaturated than those from the original menhaden oil.—*Authors' summary.*

9648. BURR, GEORGE O., and MILDRED M. BURR. On the nature and rôle of the fatty acids essential in nutrition. *Jour. Biol. Chem.* 86(2): 587-621. 1930.—In a previous paper the authors described a disease due to the absence of fatty acids from the diet. This disease is accompanied by impaired growth and the rat declines in weight until death supervenes, usually caused by kidney degeneration. In the present paper it has been shown that the saturated fatty acids fail to cure the sick animals. Those fats which contain no appreciable amount of acids more unsaturated that oleic also fail. Butter and coconut oil represent this type of fat. It would seem, therefore, that oleic acid is also valueless as a cure. All fats which contain much linolic acid (lard, olive oil, corn oil, linseed oil, egg lecithin) readily cure the animals when doses of 100 mgm. daily are fed. Pure methyl linolate is likewise an effective cure, but the whole oils seem to be somewhat better. When the curative oil is fed rapid gains in weight take place and much new fat is deposited. From this and other evidence in the literature, it is concluded that warm blooded animals do not synthesize linolic or linolenic acids and they are dependent on plants for these essential body constituents.—*G. O. Burr.*

9649. CANNAVÒ, L. Contributo allo studio del metabolismo intermedio dei grassi. Influenza della somministrazione di alcuni acidi grassi della serie alifatica sulla chetogenesi e sull'equilibrio acido-basico dell'organismo nei diabetici e negli epato-pazienti. [Influence of some aliphatic fatty acids on ketogenesis and acid-base balance in diabetes and liver diseases.] *Boll. Soc. Ital. Biol. Sperim.* 5(6): 805-810. 1930.—Almost all fatty acids produced acidosis, whereas only those with even numbers of C atoms stimulated ketogenesis. Acidosis was accompanied by ammoniuria.—*M. Comel.*

9652. COSTA, ANTONIO, e GIANCARLO PARENTI. Ricerche sulla partecipazione delle vie sanguigne del polmone e del fegato all'assorbimento di grassi dalle cavità sierose del corpo. [Participation of blood vessels of lungs and liver in the absorption of fat from the serous cavities of the body.] *Lo Sperimentale* 84(4): 257-285. 3 col. pl. 1930.—After injection of vaseline or vegetable oil into the pleural or peritoneal cavities of rabbits the serosal cells showed no phagocyted granules or particles of fat but following a transitory exudation of granulocytes an intensive reaction of histiogenic origin. While the lymph channels mainly were active in absorbing the injected fat some of this was also taken up by the blood vessels since injections into the right pleura gave rise to thrombosis in some branches of the pulmonary arteries of both lungs and in the right bronchial veins, and injections into peritoneum resulted in the presence of fat in branches of the portal vein. The authors discuss the functional significance of lipid phagocytosis by the mesenchymal elements and especially the histiocytes of the lung. They believe that true destruction of fat takes place only in the liver and that the fat found in the other organs is merely arrested and fixed there but not destroyed.—*M. L. Menten.*

9653. DAM, H. Die Bestimmung von Cholesterin nach der Digitoninmethode, besonders in Hühnereiern und Hühnchen. *Biochem. Zeitschr.* 215(4/6): 468-474. 1929.—Upon heating cholesterol with other lipids at 109° the quantity of free cholesterol falls. Upon warm saponification in vacuo and subsequent drying of the saponified extracts at temperatures below 50°, one cannot determine any loss of cholesterol. It is important in determining total cholesterol in hen's eggs and chicks that the fluid be made to 60% KOH concentration before shaking out with ether since one thereby may effect a complete splitting of the cholesterol esters. In the process of splitting sterindigitonins with boiling xylol it must be borne in mind that certain specimens of xylol give non-volatile substances upon long heating.—*H. Dam (transl. by M. B. Visscher).*

9654. DAM, H. Cholesterinstoffwechsel in Hühnereiern und Hühnchen. *Biochem. Zeitschr.* 215(4/6): 475-492. 1929.—It is not definitely known whether or not the cholesterol content of hen's eggs changes during incubation. In agreement with J. H. Mueller it was found that the ester cholesterol increased from 10% to 40% of the total cholesterol during incubation. As a result of feeding cholesterol palmitate (3 gm. daily) the ester ratio increased in one experiment from 0.08 to 0.16, with a fall to 0.12 on discontinuing. Of the cholesterol in egg yolk at most a trace is so bound to protein that it can be extracted with ether only after coagulation or hydrolysis of the protein. In 2 chicks raised to an age of 2 mos. on a diet of known sterol content, the difference between the sterol in the animal and feces, and in the food consumed was more than twice the sterol content of the egg. The Lifschutz reaction for oxycholesterol was either negative or only faintly positive with sterol from eggs or 20 day old chick embryos.—*H. Dam (transl. by M. B. Visscher).*

9655. DAM, H. Cholesterinbilanz des Hühnchens in den ersten zwei Lebenswochen. *Biochem. Zeitschr.* 232 (4/6): 269-273. 1931.—Half of each of 2 hatchings of chicks were killed at once, the others in 11-19 days after normal or special diet, and the cholesterol ester and cholesterol determined. The ester ratio decreased; the total cholesterol decreased, partly by excretion as sterols, partly by internal transformation or by change of the cholesterol in the lumen of the intestine.

9656. DAS GUHA, KARUNA, T. P. HILDITCH, and J. A. LOVERN. The composition of the mixed fatty acids present in the glycerides of cod-liver and certain other fish-liver oils. *Biochem. Jour.* 24(2): 266-290. 1930.

9657. DAVIS, RUSSELL E. The metabolism of tributyrin. *Jour. Biol. Chem.* 88(1): 67-75. 1930.—The average digestibility of tributyrin as determined by 7 trials with 5 hens was 86.9%. If two trials are excluded the average of the first trials was 91.9%. The toxicity of tributyrin is believed to be the cause of the decrease in digestibility when the same hen is used for a second trial. There was some storage of tributyrin in the depot fat when it was injected subcutaneously or intraperitoneally. The saponification number of the depot fat from injected rats was about 285, that from control rats was 195. No tributyrin was stored in the depot fat after tributyrin was fed. It is believed that the fat was transformed in part as it passed through the intestinal wall. The remainder probably was oxidized rapidly. The amount of acetone bodies excreted by both normal and phlorhizinized rats increased when carbohydrate was removed from the diet. When tributyrin was fed the excretion of acetone bodies increased, provided the diet used was very low in carbohydrate; otherwise tributyrin had no such effect. These facts are in agreement with the theory of β-oxidation of the fatty acids and the antiketogenic effect of carbohydrate metabolites. The quantitative relations between carbohydrate oxidation and fat oxidation that fix a maximum ketogenic-antiketogenic ratio for man beyond which acetone bodies appear in the urine in large amounts do not hold at all for the rat.—*Author's summary.*

9658. GAISSINSKY, B. E. Entnervung der Leber und Cholesterin der Galle. *Zeitschr. Ges. Exp. Med.* 62(5/6): 678-687. 1928.—In 2 dogs a bile-duct fistula was produced which diverted all the bile from the digestive tract to the outside through a canula; in a 3d dog a partial fistula was produced. In all 3 the sympathetic innerva-

tion of the liver was severed. In a 4th dog a complete bile-duct fistula was produced and the hepatic vagus communications severed. The collection of daily bile excretion began 5-8 days after operation. In the 3 dogs in which the sympathetic communications were severed the cholesterol content of the bile underwent sharp daily fluctuations not present in normal dogs nor in the one with the hepatic vagus innervation severed. There appeared to be no consistent relation between the cholesterol content of the blood and that of the bile; a lowered cholesterol content might exist in the blood along with a bile containing increased cholesterol, or an unchanging cholesterol content of the blood on days showing wide fluctuations in the cholesterol content of the bile. This fact bears on the question whether the section of hepatic nerves has a local or a general effect. In the dog with hepatic vagus innervation severed, the cholesterol fluctuations of the bile were approximately normal, the total amount being slightly below normal.

9659. GLUSKER, DAVID. Plasma lipid levels in normal dogs in the post-absorptive state and in fasting dogs. *Jour. Biol. Chem.* 88(1): 381-387. 1930.—In each of 10 dogs the 15 hr. postabsorptive plasma levels varied for total fatty acid by the standard deviation of ± 7.0%. The total cholesterol varied by the standard deviation of ± 6.0%, and the ratio between total fatty acid and cholesterol by a standard deviation of ± 5.8%. The total fatty acid plasma levels in each of 10 dogs over a period from the 15th to the 23rd hr. postabsorptive varied by the sigma of ± 4.1% and the total cholesterol by a sigma of ± 3.7%. The total fatty acid plasma levels in 10 dogs under controlled conditions varied from 205 mgm. % to 348 mgm. % with a mean of 271 mgm. % ± 13.0%. The total cholesterol plasma levels varied from 68 mgm. % to 188 mgm. % with a mean value of 115 mgm. % ± 28%. The highest values for total fatty acid and total cholesterol were obtained from an old dog, and the lowest values were given by young dogs.—*Author's summary.*

9660. MACALLUM, A. B. The significance of ketogenesis. *Canadian Med. Assoc. Jour.* 22(1): 3-11. 1930.—A concept of ketogenesis is presented based on the Knoop theory of β-oxidation of fatty acids. Hydroxy- and oxy-acids are produced step by step in the breakdown of the chain, but none are diffusible until the butyric molecules are reached. Hence, these only are found in the blood. The oxidation of glucose is "anti-ketogenic" only in the sense that it consumes the available O to such an extent that only a small part of the fatty acids are burned, not too much to be completely oxidized. When sugar is unoxidizable, or is wanting, "nearly all the O of the metabolizing cells is devoted to the oxidation of fats, and relatively large amounts of the 2 ketone acids are formed, the diffusion pressure of which is so great that they pass into the blood and eventually into the urine."—*W. W. Herrmann.*

9661. MARKOWITZ, CECILE, and FRANK C. MANN. The rôle of the lung in the metabolism of fat. *Amer. Jour. Physiol.* 93(2): 521-527. 1930.—Experiments were performed on dogs in an attempt to evaluate the rôle of the lung in the metabolism of fat; the analysis for fat in the blood was carried out by Bloor's method and for fat in the blood and tissues by Leathes' method. Specimens of lung were removed for analysis under aseptic conditions, and the experiments were performed after the animal had fully recovered. The fat administered was a measured amount of 30% cream, which the animals drank voluntarily. In some experiments, jejunostomy was performed aseptically at the time the specimen of lung was removed, and the fat was administered through the stoma after the animal had recovered from the immediate effects of the operation. To ascertain whether the fat was actually absorbed, the amount of fat in the lung and bowel was estimated at necropsy; the fat in the lung had not increased, nor was there any appreciable difference in the amount of fat in the blood proximal and distal to the lung, as stated by various previous workers. The results were checked histologically. It was not possible to demonstrate that the content of fat in the lung increased following the intravenous injection of citrated chyle obtained from a dog fed on fat. However, in 1 experiment, in which a highly emulsified preparation of fat was injected intravenously, there was a huge increase of fat in the lung, and a definite diminution of fat in the blood from the femoral artery as compared with blood removed from the right ventricle. The results do not support the supposition that the lung plays an especial rôle in the metabolism of fat.—*Authors' summary.*

9662. MEYER, ALICE. Vergleichende Gesamtsterin- und Sterinesterbestimmungen der Haut des wachsenden und erwachsenen Organismus. [Total sterol and sterol ester determinations in the skin of the growing and mature organism.] *Zeitschr. Kinderheilk.* 50(5): 596-607. 1931.—Skin from 36 cadavers examined for sterols with Windaus' digitonin method showed a pronounced percentage decrease with age (in other tissues there is a percentage increase). In the fetus 100 gm. dry skin contained an av. of 1.2 gm. total sterol; in the newborn, 0.65 gm.; in children, 0.49 gm.; in adults, 0.37 gm.; desquamation from scarlet fever, 0.83 gm. Of this 8.2-40.3%, usually 20%, was present as ester, without relation to age. The absolute sterol of the skin increased with age; a premature infant of 1115 gm. wt. showed only 0.19 gm. total sterol, a newborn of 3300 gm. wt., 0.58 gm.; by estimation, a 6 yr. old child had 1.7 gm., a 70 yr. old adult 4.5 gm.

9663. MORUZZI, G. Contributo allo studio dei meccanismi regolatori della colesterina esogena nell'organismo animale. [Mechanisms regulating exogenous cholesterol.] *Ateneo Parmense* 2(6): 629-646. 1930.—Cholesterol was intravenously injected into 15 normal and 15 splenectomized dogs and 1 normal rabbit. Neither in the normal nor in the splenectomized dogs did increase in blood cholesterol follow the injection (which indicates that the spleen is not the repository or regulator of cholesterol); but when (in 5 splenectomized dogs) the reticuloendothelial system was blocked with colloidal Ag or with saccharated Fe oxide, 26.6-65% of the injected cholesterol appeared in the blood of 4 of the 5 dogs.

9664. MOSSE, KARL, und R. BUSSEL. Der Einfluss der Ernährung auf die Zusammensetzung des Fettpolsters. III. Der Einfluss des Ernährungszustandes auf den Eiweissgehalt des Fettgewebes. *Jahrb. Kinderheilk.* 130(3/4): 166-171. 1931.—The fatty tissue of 31 infantile cadavers (along the linea alba) was examined for water, N, and P. By estimation per gm. dry wt., N was found to be constant at 4.1-5.8 mgm.; toxicoses or the nutritive status did not influence it. The decomposition of fat in illness did not alter the proportion of fat to fatty supporting tissue. The water could not be determined accurately because of postmortem evaporation. P was negative in all but 2 cadavers.

9665. NAIR, JOHN H. Lipase in raw, heated, and desiccated milk. *Indust. & Eng. Chem.* 22(1): 42-45. 1930.—A true lipase is a normal constituent of raw cow's milk, as indicated by increase in titratable acidity of high butterfat cream preserved with sucrose and by the development of rancid odors. Pasteurization inactivates lipolytic enzymes, the completeness of destruction depending on the time and temperature of holding. No lipase could be detected in powdered whole or skim milk desiccated by a drying system in which the fluid milk had undergone a preliminary pasteurization at 63-64.5° C. for 30 min. Rancid odors and flavors may be expected to develop in manufactured milk products if the fluid milk is not subjected to sufficient heat treatment for inactivation of lipase.—*Author's summary.*

9666. NESDWEDSKY, S. W., und A. K. ALEXANDRY. Das Verhältnis der verschiedenen Organe zu dem Cholesterin, dem Fett und den Lecithinen nach Versuchen an angiostomierten Hunden. *Pflüger's Arch. Ges. Physiol.* 219(5/6): 619-625. 1928.—The adrenals of fasting dogs of average size produce about 8 mgm. % of cholesterol. After feeding milk and egg-yolk the

transformed cholesterol is held back from the blood by the adrenals. The adrenals do not participate in fat metabolism to any extent. The kidneys do not take up fat. Since the blood from the hepatic vein shows the highest content of any venous blood, it is concluded that the formation of lecithin takes place in the liver.—*Authors' summary (transl.)*.

Zeitschr.* 222(1/3): 214-220. 1 fig. 1930.—Studies on the cholesterol composition of several livers of year-old cattle show a high content of oxycholesterol and esterified cholesterol, ascribed to the excretory function and the esterifying ferments of the liver. Among the various sources of liver cholesterol is that set free by the normal destruction of erythrocytes.—*Author's summary (transl.)*.

9670. **PINCUSSEN, LUDWIG.** Über Veränderungen des Stoffwechsels unter Bestrahlung. IV. Untersuchungen über den Fettgehalt der Organe. Von Eugen Zuckerstein. *Biochem. Zeitschr.* 207(4/6): 426-431. 1929.—Guinea pigs on a mixed diet were radiated with a mercury arc lamp for varying lengths of time when the stomach was empty, and killed 30 min. later, the percentage of ether-soluble substances of the serum was thereby increased over that of controls (from 0.355 to 0.548%); that of the heart and liver was decreased (2.60 to 1.55% and 6.16 to 2.03% respectively); while that of the kidneys and muscles was not greatly affected (2.58 to 2.34% and 0.86 to 0.89% respectively). The cholesterol content of the liver and kidneys was increased by radiation (0.185 to 0.226% and 0.208 to 0.300% respectively); while that of the serum, heart, and muscles was not changed. An appreciable increase in blood esterase was found after radiation. The effect of the injection of eosin prior to radiation was also studied in each of these cases with an inconstant result.—*L. G. Wesson.*

9671. **REED, LUCILLE L., FUMIKO YAMAGUCHI, WILLIAM E. ANDERSON, and LAFAYETTE B. MENDEL.** Factors influencing the distribution and character of adipose tissue in the rat. *Jour. Biol. Chem.* 87(1): 147-174. 4 fig. 1930.—In every case more fat was stored by rats ingesting rations rich in fat than by those on a diet rich in the carbohydrate, corn-starch. The proportionate distribution of the stored fat was similar for rats of the same sex and weight, regardless of the type of diet fed. As the rats of both sexes upon both diets increased in body weight, they stored more fat in proportion to body weight (with the single exception of rats of 150 gm. body weight ingesting the corn-starch diet which showed no increase over the rats of 50 gm. body weight). The proportion of subcutaneous fat was largest in small rats (50 gm. body weight). Male rats of 250 gm. body weight stored more fat in the perirenal fat depot than female rats; the latter tended to store more fat in the genital fat depot. The distribution of reserve fat in the ♀ rat of 180 gm. body weight, selected as representing the end of the period of most rapid gains in weight, was approximately: Subcutaneous, 50% of total fat; genitalia, 20%; perirenal fat, 12%; mesenteric fat, 10%; intermuscular fat, 5%; omental fat, 3%. The distribution of reserve fat in a normal rat was independent of the type of diet fed; however, the amount of fat stored by a rat was greatest in rats fed a ration rich in fat. No change in the distribution of fat was observed under any condition except forced exercise, voluntary running at night, and undernutrition. Forced activity and nocturnal activity increased the proportion of intermuscular fat. A decrease in the proportion of genital fat in the rats ingesting the starch diet followed either forced activity or undernutrition. The degree of saturation of the stored fat was dependent upon the diet of the rat. Fat stored in different depots showed slight variations only in degree of saturation; differences in chemical nature were not coincident with the location of the fat. In general, the chemical nature of the fat in any one depot was not changed by activity or the amount of food eaten. The single exception was the group of rats ingesting the coconut oil diet, fasted until their body weight decreased 30%.—*Authors' summary.*

9672. **REWALD, B.** Über den Phosphatidgehalt der Organe bei Verfütterung grosser Mengen von Phosphatiden. II. *Biochem. Zeitschr.* 208(1/3): 179-184. 1929.—The feeding of 30 gm. of phospholipid per day for 15 mos. to a dog resulted in an increase in the phospholipid content of the organs over the normal but in no further increase over the values found in a dog fed these large amounts of phospholipid for 6 mos. The phospholipid was completely absorbed.

9673. **REWALD, B.** Über Lipoide. VI. Lipoidgehalt in Fischorganen. Lipoide in Heringen. *Biochem. Zeitschr.* 206(4/6): 275-281. 1929.—Acetone is not adapted to the quantitative separation of the phospholipids from other lipids of fish oil because of the solubility of the phospholipids in acetone. Ethyl acetate is to be preferred. Herring muscle contained 3.6% phospholipid; roe, 13.9%; milt, 10.3%; liver, 12.6%, calculated on a dry basis.—*L. G. Wesson.*

9674. **RIBADEAU-DUMAS, L., et [E.] ANDRÉ.** De l'emploi de l'aleurone des graines oléagineuses dans l'alimentation de l'homme. *Bull. Acad. Méd.* [*Paris*] 101(18): 620-623. 1929.—The press cake of oily seeds is considered. A representative analysis, that of the aleurone of helianthus, is given. Ash content is high. Feeding trials with human infants were made. The aleurone can meet the body's need for protein. It is not a perfect food, however, but requires supplementing with a source of vitamin A, cod liver oil being used in these experiments.—*G. R. Cowgill.*

9675. **ROSENTHAL, SANFORD M., and RALPH D. LILLIE.** Functional and histologic studies of the effect of fat ingestion upon the normal and damaged liver. *Amer. Jour. Physiol.* 97(1): 131-141. 3 fig. 1931.—Experiments on 13 dogs show that lipemia (spontaneous or experimental) causes a slight impairment of liver activity as shown by a retention of bromsulphalein in the blood. This amounts to 5-11% 15 min. after injection of the dye. There is no increase in urobilinogen excretion in the urine and no elevation of bilirubin in the blood. If lipemia is produced in a dog whose liver has been previously damaged with chloroform or CCl_4, the retention of bromsulphalein amounts to 20-40%. Splenectomy and reticulo-endothelial cell blockade produce negligible disturbances in the removal of bromsulphalein from the blood. This is further evidence that this dye is removed from the blood almost entirely by the liver. Varying degrees of sustained lipemia were produced by feeding large amounts of cream to 8 dogs for 1-20 days; no appreciable amount of fat was taken up by the Kupffer cells. There are normally present in dogs considerable accumulations of fat in the biliary epithelium, both in the intrahepatic ducts and in the gall bladder. No correlation could be made between the quantity of fat in the bile duct epithelium and diet, in dogs on a high fat diet, dogs on a low fat diet, or dogs starved for 1-4 days.

9676. **SCHÖNHEIMER, R., H. v. BEHRING, und R. HUMMEL.** Über die Hydrierung des Cholesterins im

Organismus. [Cholesterol hydrogenation in the organism.] *Naturwissenschaften* 18(7): 156-157. 1930.—The cholesterol taken in food appears, in part, in the feces in the form of 2 hydrogenated isomers, koprosterol and dihydrocholesterol. A new and more sensitive method of detection reveals the presence of these hydrogenated sterols in cholesterol preparations, from all organs tested. The hydrogenated sterols in the feces are believed to arise thus, since they were not found in the sterols from the thoracic duct. Dogs in which the small intestine was severed from the large, and caused to void through an anus praeternaturalis, the large intestine leading, as a blind organ, to its own anus, excreted the hydrogenated sterols through the large intestine.

9677. SCHUETTE, H. A., and RALPH W. THOMAS. The composition of the fat of the silver black fox. *Trans. Wisconsin Acad. Sci. Arts and Lett.* 25: 113-116. 1930.—A quantitative analysis is reported (from animals bred in captivity). Glycerides of palmitic, stearic, oleic and linoleic acids are present. The fat has a composition similar to, but not identical with, that of the wild fox.

9678. SCOZ, G. Ricerche sul metabolismo dei grassi. V. Il glicogeno nel connettivo sottocutaneo e nell'omento. [Studies on fat metabolism. V. The glycogen content of subcutaneous connective tissue and of the omentum.] *Boll. Soc. Ital. Biol. Sperim.* 5(4): 472-473. 1930.—During fasting and feeding with carbohydrates and fats the glycogen content was found to vary correspondingly in the subcutaneous connective tissue and in the omentum.—*M. Comel.*

9679. SCOZ, G. Ricerche sul metabolismo dei grassi. VI. Il contenuto in glicogeno del tessuto adiposo sottocutaneo di animali alimentati con carne. [Studies on fat metabolism. VI. Glycogen content of subcutaneous adipose tissue in animals fed with meat.] *Boll. Soc. Ital. Biol. Sperim.* 5(4): 479-481. 1930.—The glycogen content of adipose tissue of dogs kept fasting or on a low diet did not vary with the kind of food. On overfeeding or refeeding with bread, the glycogen content was 500-3000 mgm. per 100 gm. tissue, whereas it was less than 200 mgm. if the dogs were fed with meat. The glycogen content shows thus an increase during alimentation when bread is given but not with a meat diet.—*M. Comel.*

9680. SINCLAIR, ROBERT GORDON. The metabolism of the phospholipids. 1. The influence of diet on the amount and composition of the phospholipid fatty acids in various tissues of the cat. *Jour. Biol. Chem.* 86(2): 579-586. 1930.—The degree of unsaturation of the phospholipid fatty acids in the liver, heart, kidneys, smooth and skeletal muscle, intestinal mucosa, and probably the brain was consistently higher when cats were fed on an exclusive diet of beef kidney than when fed on hashed beef muscle. This fact may indicate either that phospholipid is intermediary in the metabolism of fat or that the tissue phospholipids undergo continual wear and tear and replacement at the expense of food fat. The amount of phospholipid fatty acids in all tissues except the liver was the same for both diets; in the liver there was a greater content of phospholipid when beef kidney was fed than when the diet consisted of beef muscle.—*Author's summary.*

9681. SINCLAIR, ROBERT GORDON. The metabolism of the phospholipids. 2. The influence of growth of the phospholipid (and cholesterol) content of the white rat. *Jour. Biol. Chem.* 88(2): 575-587. 1930.—A study of the content of phospholipid fatty acids and unsaponifiable material in the entire bodies of white rats during the first 4 mos. of life has shown: That the phospholipid content, expressed in relation to the tissue solids, decreases rapidly after birth, the period of most rapid decline in the phospholipid content coinciding with the period of most rapid growth. On account of the rapid decrease in the water content of the tissues of the rat as a whole during the first few weeks of postnatal life, the phospholipid content of the moist fat-free tissues increases rapidly after birth, reaches a maximum in about 3 weeks, and then declines throughout the remainder of the period studied. The ratio phospholipid fatty acids: unsaponifiable material remains practically constant during the first 3 mos. of life.—*Author's summary.*

9682. STIRPE, GIULIO. Sulle variazioni del tasso colesterinico del siero di sangue nell'uomo nel regime alimentare ipercolesterinizzante in condizioni normali e patologiche. [Cholesterol content of human blood serum, normal and pathologic, during the use of a high cholesterol diet.] *Policlinico [Sez. Pratica]* 37(45): 1625-1630. 1930.—A high cholesterol diet, given in the form of 4-8 eggs a day for 4-10 days to each of 30 persons (10 normal, 10 hypertonics, 10 with hepatic calculi) produced no perceptible changes in blood serum cholesterol. The 20 pathologic cases were more or less distinctly hypercholesterolemic.

9683. SUSSO, BIONDI G. Sull'incapacità dell'organismo degli uccelli di condensare l'urea coll'acido glicerico. [Inability of birds to conjugate urea with glyceric acid.] *Boll. Soc. Ital. Biol. Sperim.* 5(6): 980-981. 1930.—Administration of glyceric acid and glycerol per os to chickens and geese was not followed by increased uric acid excretion, even when in the meantime urea was administered. Most of the urea was excreted as such, a minimal portion being converted into ammonia.—*M. Comel.*

9684. TAKAHASHI, W. Über die Tributyrinspaltung im Blute und Serum verschiedener Tiere. *Pflüger's Arch. Ges. Physiol.* 225(1): 42-48. 4 fig. 1930.—The method of Rona and Michaelis was used. With the defibrinated bloods of animals the following series was obtained, in order of their hydrolyzing power: rabbit, cat, horse, man, dog and ox. This order does not agree with that obtained by Galehr and Plattner for acetylcholin. In cat and horse blood the serum contained all of the hydrolyzing power while in the other animal bloods studied the formed blood constituents contributed to this power. Urethane anesthesia decreased this hydrolytic power of rabbit blood.—*Author's summary (transl. by A. G. Mulder).*

Internat. de Physiol.* 26(3): 295-300. 1926.—Dog blood, drawn aseptically and preserved in hermetically sealed tubes at 37° for about a year, showed no change in either total fatty acids, unsaponifiable, or cholesterol.

9686. THIERFELDER, H., und E. KLENK. Die Chemie der Cerebroside und Phosphatide. viii+224pp. (Bildet Bd. 19 der "Monographien aus dem Gesamtgebiet der Physiologie der Pflanzen und der Tiere.") [(Vol. 19 of "Monographs of the entire field of plant and animal physiology.")] J. Springer, Berlin, 1930. M. 19.60.

9687. TIMON-DAVID, J. Recherches sur les matières grasses des insectes. *Ann. Fac. Sci. Marseille* Sér. 2. 4(2): 29-207. 4 pl. 1930.—This work is a comparative biochemical study of the composition of the fats in a number of species of insects, of the metabolism of these fats, and of the factors that may influence the latter. The fatty substances were extracted with ether or petroleum ether. Oils, liquid at ordinary temperatures, were obtained from *Pyrausta nubilalis* Hübn. and *Ergates faber* L., solid fats from *Rhynchophorus palmarum* L., and "butters" with a crystalline aspect from *Pemphigus utricularius* Pass. and *Aphis rumicis* F. The waxes were left entirely out of consideration. The fat content of a species is constant, but varies greatly among species of different groups. In larvae the fat content is sometimes considerable. On a live weight basis *Pyrausta nubilalis* Hübn. yields 26.5% fat, *Balaninus elephas* Gyll. 28%, *Cossus ligniperda* F. 27.5%. In other species the yield is less; e.g., 13% in *Ergates faber* L. In still others it is low; e.g., 1.5% in *Lymantria dispar* L., 0.94% in *Lycophotia margaritosa* Haw. The chemical properties of the substances extracted vary considerably. The iodine number ranges from 164.5 in *Saturnia pyri* Sch. to 7.5 in *Pemphigus*. Intermediate values are 112 in *Thaumetopoea pityocampa* Sch., 80.8 in *Pyrausta*

nubilalis Hübn., 39.8 in *Rhynchophorus palmarum* L., and 16.2 in *Aphis rosae* L. The saponification numbers are remarkable in the aphids where 255 is reached in *Pemphigus utricularius* Pass., and 265.7 in *Aphis rumicis* F. The content of unsaponifiable matter is generally low, being in no case as high as in the waxes. By Leys' method 0.75% was found in *Ergates faber* L., 1.68% in *Pyrausta nubilalis* Hübn., 8.5% in *Thaumetopoea pityocampa* Sch., and 10% in *Pieris brassicae* L. The content of non-saturated acids ranged from 82% in *Pyrausta nubilalis* Hübn., to 40.5% in *Rhynchophorus palmarum* L. It could not be determined in aphids, but it is certainly very low. Raising the temperature appears to lower the iodine number. The character of the food of the insect has a great influence on the fat content and on its chemical composition. The larvae that are richest in oil are those that feed largely on glucids (*Balaninus elephas* and *Cossus ligniperda* F.) or on lipids (*Docus oleae* and *Pachymerus acaciae*). In the latter case the composition of the oil depends partially on that of the oil ingested. Hibernation in *Pyrausta nubilalis* Hübn. does not lead to any diminution of the reserve of oil accumulated by the beginning of winter, but metamorphosis is accompanied by a considerable disappearance of fat. Saturated and non-saturated fatty acids are lost equally in *Pyrausta nubilalis* Hübn., but in *Pieris brassicae* L. the non-saturated acids suffer the greater loss. The fat content of females is often greater than that of males. The fats of species of the same family are generally of similar composition, which is explained in most cases by the similarity of their food. —*J. Timon-David* (*transl. by F. L. Campbell*).

9688. VERNE, JEAN. Démonstration histochemique de la formation de corps a fonctions aldéhydiques aux dépens des enclaves graisseuses et lipidiques. *Compt. Rend. Soc. Biol.* 99(22): 266-269. 1928.—Oxidation of the visible lipids of cells (stainable with Sudan) causes the formation of bodies which give the Schiff reaction for formaldehydes.

9689. ZAGAMI, V. De la cétogenèse en fonction de la nature de l'alimentation chez le porc. *Arch. Internat. Physiol.* 33(2): 159-172. 1930.—From experiments of which 3 are detailed Zagami concludes that on strict glucide diet, the pig excretes an abundance of ketone compounds; when either a strict protein or a strict fat diet (especially the latter) is substituted, the excretion of ketone bodies increases, the increase affecting only β-oxybutyric acid in the case of the protein diet, but involving all the ketone compounds in the case of the fat diet. Ammonia excretion is not parallel with that of the ketone bodies, being higher on a protein than on a fat diet, while ketone production is higher on the fat diet. Ammonia production depends both on the degree of acidosis and the amount of N metabolism.

9690. ZAKOLSKA, ZENOBJA. Badania histochemiczne nad ciałem tłuszczowem larw i poczwarek Tenebrio molitor. [Histochemical researches on the adipose tissue of larvae and nymphs of T. molitor.] [With French résumé, p. 794-797.] *Kosmos* [*Lwów*] 53(4): 779-797. 2 pl. 1928(1929).—This tissue surrounding the alimentary tract may contain neutral fats, fatty acids, albuminoid substances and glycogen; the peripheral fat body lacks albuminoids. The granules of the cells are termed albumino-fatty granules for they react as albumins as well as fatty acids. Neutral fats appear in very large amounts in the young larva (0.5 cm.) while only traces of fatty acids and albumins are found. These increase with the growth of the larvae. Maximum neutral fats are present in the pupa while the fatty acids and albumins reach their peak in the fully grown larva. Contrary to other writers, the quantity of albumino-fatty granules seems to remain constant during histolysis. There is a diminution in the amount of the granules present in certain cells at the close of metamorphosis. Glycogen appears in the larva of 0.7-0.9 cm. and reaches its peak in the larva with a length of 2.8-3 cm. It is reduced to a mere trace at the beginning of pupation, in the peripheral fat body and in the hypodermal cells, a diminution believed to be due to the reduction of metabolic processes. The reduction of glycogen in the adipose tissue is unquestionably due to the increase of reserve material in the oöcytes. Glycogen also has a specific rôle in molting for, while absent from the hypodermal cells prior to molting, it is present afterward. Its fluctuation in quantity is of significance in the formation of chitin.—*Author's summary* (*transl. by H. R. Hagan*).

MINERAL METABOLISM

9691. ARNOLDI, WALTER. Der Einfluss verschiedener Ernährung auf die Glauberquellwirkung. [Effect of different diets on the action of mineral (Na_2SO_4) water.] *Zeitschr. Ges. Exp. Med.* 73(3/4): 458-463. 1930.—Of 6 rats 3 were kept on a fat-and-protein diet and 3 on a carbohydrate-rich diet. During a preliminary period of 2-3 wks. the fat-and-protein diet increased weight more than the carbohydrate-rich diet. The administration to all the rats of Na_2SO_4 water reversed the relations. The rats on fat-and-protein now decreased in weight, and excreted more Ca, P and "Vakat-O." The rats on carbohydrate-rich diet tended to increase in weight, the urinary Ca and P excretion did not increase so much, and the oxidative processes judged by the "Vakat-O" were only slightly affected.

9692. BACHARACH, A. L. Effect of added iron on the haematopoietic properties of dried milk. *Lancet* 219 (5592): 957-958. 1930.—Hart, Steenbock technique was used on albino rats of the Wistar Institute Tyler strain; hemoglobin estimations were made on a Dare hemoglobinometer. Controls (3 ♂♂ and 2 ♀♀) were given unlimited fresh cow's milk; experimental animals (likewise 3 ♂♂ and 2 ♀♀) received dried milk plus Fe, reconstituted with 7 times its weight of water. The hemoglobin index was almost constant and normal in animals fed dried milk, but was rapidly lowered in control series. The food intake was found to be almost constant, above 40 gm. milk per rat per day. The controls grew more rapidly, average increases in weight in 60 days being 28 and 35 gm. Raw milk had 1.5-2.0 Fe and 0.4 Cu: dried milk 5 Fe and 0.23 Cu parts per million of liquid milk used. The author concludes "that the recognised low hematopoietic properties of milk solids can be materially enhanced by drying in the milk appropriate quantities of a suitable Fe salt, and that in this way a dried milk may be prepared containing sufficient Fe and Cu to allow normal hemoglobin formation in the young growing albino rat."

9693. BERTRAND, GABRIEL, et VORONCA-SPIRT. Recherches sur la présence et la répartition du titane chez les animaux. *Ann. Inst. Pasteur* [*Paris*] 45(1): 102-106. 1930.—Ti was found in tissues of the horse, calf, sheep, pig, rabbit, chicken, whiting, mackerel, carp, smelt, turtle, shrimp, snail (2 species), Portuguese oyster and 3 other shellfish.

9694. BERTRAND, GABRIEL, et Y. BEAUZEMONT. Sur les variations de la teneur en zinc des animaux avec l'âge: influence du régime lacté. [Variations in the zinc content of animals with age: influence of milk diet.] *Ann. Inst. Pasteur* [*Paris*] 45(2): 247-250. 1930.

9695. BETHKE, R. M., D. C. KENNARD, and C. H. KICK. The availability of calcium in calcium salts and minerals for bone formation in the growing chick. *Poultry Sci.* 9(1): 45-50. 1929.—Calcium in the form of carbonate, sulphate, lactate and phosphate salts, or as the commonly used minerals: limestone, steamed bone meal, rock phosphate, phosphatic limestone or oyster shells, was found to be equally available for bone formation in the growing chick. Best calcification was observed in one experiment in which $CaCO_3$ was used when the Ca level of the ration was 0.858% and P 0.442%.—*F. E. Mussehl.*

9696. BISHOP, WILFRID B. S. The occurrence of lead in the egg of the domestic hen. Part III. *Med. Jour. Australia* 1(24): 792-806. 13 fig. 1929.—Weights of eggs from a Black Orpington hen and a white Leghorn hen averaged, over 6 and 9 mos., 59.58 gm. and 55.70

gm. respectively, with an average loss during incubation of 0.573 gm. and 0.438 gm. The weights of embryos from White Leghorn eggs were found to be in good agreement with previous results as were also the ashes of the embryos. Absorption by the embryo of the Pb naturally present in the egg and of injected Pb compounds was studied. From 31.5 kgm. of yolk material, 0.0106 gm. of a twice precipitated substance which analysis suggests to be a lead lecithin compound, and 0.2860 gm. of lead oleate were obtained. Schemes for the separation of these substances are given.—*W. B. S. Bishop.*

9697. BOYCOTT, A. E., and G. R. CAMERON. Manganese in foodstuffs. Its possible relation to cirrhosis of the liver. *Lancet* 219(5592): 959. 1930.—Since Mn salts have been shown (Hurst) to be effective in producing cirrhosis of the liver (rabbits), a condition which is associated with but apparently not directly due to chronic alcoholism (man), the authors conjectured that in chronic alcoholism, abnormal appetites might lead to selection of a diet high in Mn. Shell fish, condiments, tea, coffee and cocoa were analyzed and were found in general to contain only traces or small quantities of Mn. It is concluded that "a vegetarian teetotaler will probably take in more Mn than a heavy drinker."

9698. BOYD, O. F., and J. F. LYMAN. Utilization of calcium soaps by the white rat. *Proc. Soc. Exp. Biol. & Med.* 27(8): 871-873. 1930.—Male rats, about 35 days old, on a diet consisting of: casein, 18%; mineral salts, 3%; sucrose, 35%; starch, 36%; various Ca soaps, 4 or 8%; yeast, 0.2 gm. daily; and cod-liver oil, 2 drops daily, utilized Ca palmitate to the extent of 38-66%; Ca oleate, 90%; Ca stearate, 25-45%; and mixed Ca soaps from lard, 70-75%.

9699. CHARIT, A. J. Phosphorstoffwechsel im Intermediärgebiet nach Versuchen an angiostomierten Hunden. *Pflüger's Arch. Ges. Physiol.* 218(5/6): 642-646. 1928.—Five organs take part in intramediary P metabolism. The intestine absorbs the inorganic P from the chyme; the liver holds back part and uses part of its P in forming compounds in response to hormones from the pancreas and the adrenals; the P that passes through the liver is in part held by the kidney and in part excreted.

9700. COMPERE, EDWARD L. The effect of phosphorus in rickets. II. Chemical changes in the blood in rickets following administration of phosphorus. *Amer. Jour. Dis. Children* 40(6): 1177-1192. 1930.—In the 2 papers of this series, Compere has reported the roentgenographic changes in the bones and the chemical changes in the blood of 10 rachitic infants and 1 nonrachitic patient following the administration of cod liver oil, elementary P or a combination of the 2. The results parallel roentgenographic studies. The reaction of the blood serum is not important in the healing of rickets in infants. P alone does not cause any significant change in the Ca or P content of the blood serum, or in the product of the 2, when administered in minute doses in cases of severe rickets in which there has been no initial stimulation from ultraviolet light or from the administration of cod liver oil, nor does it cause healing of the rickets. Cod liver oil administered alone to infants with severe rickets causes a definite increase in the product of the Ca content and P content of the blood. When P was administered together with cod liver oil the product of the Ca and P increased rapidly. The combination of P and cod liver oil appears to produce more prompt and more certain healing of rickets.

9701. DELBET, PIERRE, et PIERRE BRETEAU. Vieillissement et magnésium. *Bull. Acad. Méd.* [*Paris*] 103(10): 256-266. 1930; also in: *Rev. Internat. Med. et Chir.* 41(3): 30-35. 1930.—The ameliorating effect of halogen salts of Mg in certain diseases associated with old age suggested the possibility that Mg diminishes in the body with advancing age. The Mg: Ca ratio was therefore studied in the testicle and in the brain. In the testicle (number of subjects not stated) the Mg: Ca ratio in infants of 1 mo. and 3 mos. was 1, in adults (35-45 yrs.) 0.8, and in old people (over 65) 0.34. In 5 brains the ratios were 0.65 (40 yrs.), 0.8 (45 yrs.), 0.36 (68 yrs.), 0.2 (74 yrs.), 0.33 (75 yrs.). The absolute figures of Ca and Mg were more variable, but the ratios appeared to sustain the theory of a comparative accumulation of Ca and loss of Mg with advancing years.

9702. DUBUISSON, M., et J. van HEUVERZWYN. Nouvelles recherches sur la répartition du manganèse chez les mollusques. *Arch. Internat. Physiol.* 33(1): 86-91. 1930.—The lamellibranchs examined (*Tapes, Avicula, Mytilus, Pinna*) were relatively poor in Mn as compared with another mollusk of the same group, *Anodonta cygnaea*, in winter. In *Pinna* (as also in *Anodonta*) marked individual variations were found. The branchiae of *Mytilus* and *Pinna* (like those of *A. cygnaea*, in winter) were richer in Mn than the other tissues. The gastropods examined had variable Mn contents even when gathered at the same time and in the same submarine region. The high proportion of Mn in *Cerithium vulgatum* Brug and *Turitella communis* Risso is under histologic investigation.—*From authors' summary (transl.).*

9703. FOWEATHER, F. S., and C. J. POLSON. Iron storage in splenectomised rabbits. *British Jour. Exp. Path.* 11: 362-368. 1930.—Parallel experiments were done on intact and splenectomised rabbits. These were given 160 mgm. of Fe intravenously in divided doses and were killed in pairs at intervals ranging from 1 day to 2 mos. after the last dose. A series of controls not receiving Fe was also done. The organs of all the animals were examined chemically and histologically; iron was determined by the authors' method. The absence of the spleen does not affect the storage of Fe, its principal center being the liver. Failure to find a reservoir of Fe in the lungs precluded the possible function of the spleen in the transference of Fe from the lungs to the liver. The presence of a pigment was noted and yielded the staining reactions ascribed to hemofuscin by Mallory. Since the only new factor recognized in these experiments, repeating similar ones in which this pigment was not found, was the addition of mangels to the diet, these may be responsible for the pigment.—*J. Bland.*

9704. HAAM, EMERICH. Zur Frage des Einflusses der Milz auf den Eisenstoffwechsel. V. [Influence of the spleen on iron metabolism.] *Zeitschr. Ges. Exp. Med.* 73(1/2): 83-91. 1930.—The feces of 2 dogs, a ♂ and a ♀, were analyzed before and after splenectomy; also the feces of a ♀ non-splenectomized control. Contrary to the findings of Asher and Nakajama, but in agreement with the majority of authors, splenectomy did not increase the Fe in the feces.

9706. KALBERMATTEN, RUDOLF. Das Verhalten des Eisenstoffwechsels bei normalen und milzlosen Tieren in der Unterdruckkammer. (LEON ASHER. Beiträge zur Physiologie der Drüsen. Nr. 122.) *Biochem. Zeitschr.* 226(4/6): 429-440. 3 fig. 1930.—That the spleen is an organ concerned with Fe metabolism, has been amply demonstrated. Other organs (the liver or reticulo-endothelial system) may take over this function after the spleen has been removed. The author's plan was to ascertain the amount of Fe excreted in the feces of normal and splenectomized guinea-pigs when placed in a chamber under reduced pressure (300 to 350 mm. Hg). A description of the method, apparatus used, and the method for determining the Fe is given. In 3 animals there was an increase of 46, 30, and 10% in the excretion of Fe per day immediately after extirpation of the spleen. A second experimental period, 8 to 10 days later, showed an increase of 80, 12, and 0% in the excretion of Fe for the same animals respectively. The results for the 3rd animal demonstrate that some other

tissue in the body had compensated completely for the spleen in regulating Fe metabolism. In the 2nd guinea pig there was some compensation, while in the 1st the compensatory mechanism failed. These experiments uphold the theories that the spleen is an organ of Fe metabolism and that other body tissues gradually assume this function after splenectomy.—*P. E. Claus.*

9708. **LOEW, O. Das Calcium im Leben der Haustiere.** 64p. O. Gmelin, Munchen, 1930.—This monograph treats chiefly the application of $CaCl_2$ to the promotion of physiological functions and to the prevention and curing of various diseases of domestic animals. Calcium chlorid is directly useful as long as the urine of the animals shows an alkaline reaction. When, however, the feeding of animals is such that the urine becomes *acid* as is, e.g., the case with hogs fed chiefly on seeds of various kinds, $CaCl_2$ can have a favorable effect only when at the same time provision is made for raising the blood alkalinity necessary for Ca assimilation. Such is the case also when cows are fed with a great excess of protein in order to increase the yield of milk. Of special interest is the promotion of fertility by feeding $CaCl_2$. The author proposes a classification of food articles as physiologically acid or alkaline.—*O. Loew.*

9709. **LUNDSGAARD, EINAR. Weitere Untersuchungen über Muskelkontraktionen ohne Milchsäurebildung.** *Biochem. Zeitschr.* 227(1/3): 51-83. 1930.—The failure of lactic acid formation to occur during work by muscles poisoned by monoiodoacetic acid was confirmed. The ratio between phosphagen splitting and work during single twitches and tetany (expressed as $K_{mP}-$ and $K_{zP}-$) was determined. Simultaneous curarization does not alter the $K_{mP}-$ and $K_{zP}-$ values of muscles so poisoned. The chronaxie of iodoacetic acid-poisoned muscles was found normal and on simultaneous curarization was increased to the same extent as by curarization alone. Anaerobic phosphagen resynthesis does not occur after poisoning by iodoacetic acid. Muscles only moderately poisoned performed in O more work with a lesser diminution in phosphagen content than in N, indicating the occurrence of oxidative phosphagen resynthesis. The time course of the esterification as well as the nature of the esters formed was investigated. A splitting of pyrophosphate during work and rigor development was demonstrated.—*Author's summary (transl. by F. F. Heyroth).*

9710. **McCARRISON, R. Effect of manganese on growth.** *Far East. Assoc. Trop. Med. Trans. 7th Cong. Brit. India.* 3: 343-344. 1927[1928].—Manganese dioxide ingested by young rats to the extent of 0.889 mgm. daily, representing a concentration of 1 part of Mn to 12,600 parts of the food eaten, exercised a progressively retarding influence on growth. This retarding action was manifested only after 32 days' consumption of the salt, and appears to have been cumulative. Manganese chloride when ingested by young rats to the extent of 0.0327 mgm. daily, representing a concentration of 1 part of Mn in 617,700 parts of the food eaten, exercised a markedly favorable influence on growth. The conclusion appears justified that concentrations of Mn of the former order are harmful to the animal organism; while concentrations of the latter order are beneficial. And since a diet containing a fair proportion of whole wheat provides a concentration of Mn of the latter order, it may be concluded that the growth-promoting properties of whole wheat are in part due to the content of Mn in this cereal.—*Author's results.*

9714. **MATTERS, REGINALD FRANCIS. A study of calcium metabolism in the human female.** *Australian Jour. Exp. Biol. & Med. Sci.* 6(2): 119-125. 1929.—Calcium was determined in the blood, during various stages of the menstrual cycle, in 70 patients, 30 of whom were studied consecutively enough to give conclusive data. The blood Ca was highest 5 days before menstruation, falling rapidly until about the 3rd day of menstruation, and then rising gradually. Allowing for errors in the sampling and in the analysis, the variation was at least 5%.—*M. Dann.*

9715. **MELLI, GUIDO, et GUGLIELMO TASSO. Sur le sort du chlorure de sodium et d'autres sels injectés par voie intraveineuse.** *Rev. Belge Sci. Méd.* 2(3): 209-225. 1930.—A dose of NaCl several times the content of the entire blood mass was rapidly injected into the carotids of rabbits. In some the renal pedicles were tied, in others the stomach was excised, in still others both gastrectomy and ligature of the renal pedicles was performed, while in the last group nearly all the abdominal organs were removed. Some were bled to death in 5 min. after the end of the injection and the NaCl of the blood and organs determined; most of those not so killed survived for several hrs. with normal heart-beat and respiration. In all 4 groups the injected NaCl disappeared from the circulation as a rule in 5-10 min. It was evidently not eliminated, since the results were not influenced by removal of the stomach and kidneys, the principal chlorid emunctories. A rise of NaCl content was observed in the various organs and tissues, but particularly in the skin. The blood was found highly concentrated after injection of heavy doses of NaCl, apparently owing to the abstraction of water by the NaCl fixed in the tissues. The NaCl content of the blood returned almost to normal soon after the NaCl injection; but for some days there was a slight elevation of NaCl content, which may represent NaCl in transit from the organs and tissues to be eliminated. Exceptionally, in some animals, NaCl injection was followed by death in convulsions; in these animals a high NaCl content of the blood persisted for several min. Whether death was due to the inability of the organs and tissues to remove the NaCl from the blood, or whether the approach of death prevented the fixation of NaCl in the tissues is uncertain. Other chlorides (KCl, $CaCl_2$) behaved like NaCl. Therapeutic intravenous injections of NaCl in man gave a similar blood picture.

9716. **MORRIS, NOAH, and OLIVE MacRAE. Metabolic reactions to acidosis produced by ammonium chloride.** *Arch. Dis. Childhood* 5(27): 207-228. 6 fig. 1930.—The effect of prolonged administration of NH_4Cl on the metabolism was studied in 4 apparently normal children, in none of whom was produced any clinical manifestation of acidosis. The CO_2 content of blood was reduced; the reduction almost always reached its maximum early in the administration of NH_4Cl. The Cl content was moderately increased, but the increase did not exactly balance the deficiency in CO_2. The fixed base remained within normal limits except in 1 case where it was reduced by 15 milli-equivalents. Ca was slightly increased and P slightly diminished. Non-protein N was slightly increased but within normal limits. There was an increased output of Ca both by urine and feces and consequently a decreased retention. Evidence is adduced

in favor of the excretion of Ca through the bowel wall. There was an increased excretion of P by urine and feces and a diminished retention. There was a slightly increased retention of Cl. There were usually 2 peaks in the excretion of chloride: they occurred about the 2nd and 6th days. The 2nd peak usually coincided with the maximum output of NH_3. There was an increased excretion of fixed base both by urine and feces; the extra fecal base consisted chiefly of Ca. The metabolic reactions of acidosis are discussed, and it is suggested that the increase in the output of Ca and P is the result of the response of the osseous tissues and forms a reaction of prime importance in preventing acidosis.—*Authors' summary.*

9717. **MORRISON, DEMPSIE B., and THOMAS P. NASH, Jr. The copper content of infant livers.** *Jour. Biol. Chem.* 88(2): 479-483. 1930.—Analyses of the livers of 25 infants gave an average of 24.0 mgm. of Cu per kgm. of fresh tissue or 6 times the average value for 7 adults. The highest value for an adult was lower than any of the values for the infants, with the exception of 1 infant case with severe anemia.—*Authors' summary.*

9718. **MURDOCH, GEORGINA. A study of phosphorus absorption in normal and rachitic children.** *Arch. Dis. Childhood* 2(11): 285-301. 1927.—The level of the inorganic P in the serum in normal and rachitic children was followed for several weeks, during which alterations were made from time to time in the intake of Ca and P. The 1st part of the study was conducted on 3 rachitic children from 1¼ to 1¾ years of age and on 8 non-rachitic children from 5 mos. to 10 years old. A diet poor in Ca and rich in P gave rise to an increase in the P content of the serum, though not beyond normal limits. Subsequent addition of Ca in excess to the diet induced a fall in the serum P, more marked in the rachitic than in the normal children. The P absorptive power, as indicated by the rise in the inorganic P of the serum following the ingestion of 4 gm. of NaH_2PO_4, was separately investigated in 11 children, of whom 5 were normal, 4 had active and 2 healing rickets. It was found that in the cases of active rickets the average absorption was the same as in the healthy children, while in those with healing rickets it was abnormally high.—*T. C. Hempelmann.*

Res.* 40(2): 191-199. 8 fig. 1930.—It was found that the utilization of Ca in normal bone growth seemed to depend upon two factors, its assimilation, and its fixation in the bone cell itself. Adding 0.5% of Mg in the form of carbonate and sulphate to the basal mixture of corn, wheat, and milk proteins did not markedly affect the rate of growth of chicks, but rickets resulted from the $MgCO_3$ additions.—*H. W. Marston (courtesy Exp. Sta. Rec.).*

9720. **NATHAN, E., und FR. STERN. Über den Mineralgehalt der Haut unter normalen und pathologischen Bedingungen. VI. Über Schwankungen im Kalium-, Kalzium-, Chlor- und Wassergehalt der Kaninchen- und Meerschweinchenhaut bei gleichmässiger Ernährung und bei Hunger und Durst.** *Dermatol. Zeitschr.* 60(5): 299-313. 1931.—In 14 rabbits and 11 guinea pigs kept on a uniform diet and under identical conditions frequent examinations of small skin fragments, taken at various intervals, revealed more or less considerable fluctuations in the K, Ca, Cl, and H_2O content of the skin. In 4 rabbits fasted for 7 days, 7 guinea-pigs fasted for 4 days, 9 fasted for 3 days, and 3 fasted and thirsty for 3 days, the skin of most animals lost minerals and H_2O. The few exceptions indicate an exchange between the skin and other water and mineral reservoirs of the organism (subcutaneous cellular tissue, musculature, and bones). Considering the functional significance of the ionised part of the minerals in question, one must assume, in spite of the considerable mineral variations found in the skin, that the ionised part is more constant than the total, for otherwise regulation of the tissue's vital processes could not exist.

9721. **NEDSWEDSKY, S. W. Verhältnis zwischen Kalium, dialysierbarem und undialysierbarem Calcium im Intermediärgebiet nach Versuchen an angiostomierten Hunden.** *Pflüger's Arch. Ges. Physiol.* 218(5/6): 647-654. 1928.—K is absorbed faster than Ca by the intestine from mixtures of the 2. In the intestinal wall the absorbed Ca and part of the Ca that is present in the circulating blood is believed to be bound in colloidal form. The method of angiostomy has uncovered the Ca-binding function of the intestine. The quantitative relation between the dialyzable Ca is the reverse in the liver of what it is in the intestine. There the Ca that is in colloidal form is transformed into free Ca and with the K of the general circulation passes to different organs. During its passage through the intestine a part of it is again bound in colloidal form. The greater part of the K is excreted in the kidney; the quantity excreted (3.5 mgm. %) is nearly the same as the amount resorbed (3.9 mgm. %); the Ca excreted is very small (trace to 0.3 mgm. %) and comes entirely from the dialyzable fraction. The spleen holds back part of the K that the intestine furnishes but does not alter blood Ca.

9722. **NEWCOMB, CLIVE, and GANAPATI SANKARAN. A note on iodine metabolism.** *Far East Assoc. Trop. Med. Trans. 7th Cong. Brit. India* 3: 329-334. 2 graphs. 1927[1928].

9724. **OEHME, C., M. OEHME, und H. WASSERMEYER. Über Gesetzmässigkeiten des Mineralstoffwechsels.** *Deutsch. Arch. Klin. Med.* 154(2/4): 107-130. 1927.—The organism regulates its physiologically specific ionic balance just as it regulates the acid-base balance. In 2 diets of known mineral composition, addition of various salts (NaCl, KCl, $NaHCO_3$, $KHCO_3$), brings on antagonistic alterations of the added as well as of other ions present. There is evident antagonistic action between the kations (Na,K) and the anions (Cl,HCO_3). The deposition of Ca and P due to the intake of NaCl is dependent not only on the ionic mixture, but also on the absolute magnitude of the Ca and P intake, when this does not coincide with the absolute minimum. KCl may bring on a deposition in the presence of a diet deficient in Ca and P while NaCl produces a negative balance. The specific action of neutral salt ions interferes to a certain extent with the acid-base balance; it appears under certain circumstances to control it. According to the diet, NaCl influences the acid-base balance in different (opposite) directions. The same feature is at least probable in the case of KCl, although the conditions under which an acidotic or alkalotic effect appears are not yet clear. The action of $NaHCO_3$ and $KHCO_3$ on the Cl balance depends in the first place on the Na content of the food, that is, the magnitude of the quotient Na/K. The results permit an insight into the rules according to which the ionic mineral-exchange takes place in the body. The rôle played by the intestinal tract is briefly discussed. These balance reactions were observed on 3 persons, and were supplemented by findings from the literature. They depend on the pre-experimental period. The assumption is made that the ionic mixture of the trans-mineralisation stream of the food regulates all elements coordinated in mineral metabolism. From this a few conclusions are drawn regarding possible goals of a general mineral therapy.—*Authors' summary (transl. by A. Bolliger).*

9725. **ORR, J. B., and I. LEITCH. Iodine in practical agriculture.** *Internat. Rev. Agric. Pt. 1. Month. Bull. Agric. Sci. and Pract.* 21(6): 197-208. 1930.—This review of work on the influence of I on plant and animal nutrition shows a mass of conflicting data. There is little doubt however that under certain conditions and on certain diets, the administration of I to animals may be beneficial.

9726. **PARKER, HAYWOOD Jr., and FRANK C. VILBRANDT. The iodine content of shrimp waste.** *Jour. Amer. Chem. Soc.* 53(2): 633-635. 1931.—The wastes of shrimp fisheries showed a content of 16.9 parts per mil-

lion of I calculated on the dry basis. Alcohol extraction indicated that 44.14% is organic; ether extraction that 55.86% is lipid I. No thyroxine chould be detected in the extract of shrimp waste when tested by the Kendall method.—*Authors' summary.*

[Alkaline reserve, calcium and phosphorus in the blood of animals in which the bile is completely diverted.] *Arch. Ital. Chir.* 28(2): 163-174. 1931.—External cholecystostomy was performed on 4 dogs; 3 survived for 100-178 days and the 4th was killed 186 days after operation. X-ray examination showed an osseous decalcification. Blood examination showed a progressive acidosis, diminution of P and a normal Ca level, agreeing with the findings in human and experimental rachitis.

9728. **RASK, O. S., and E. V. McCOLLUM.** The biological significance of aluminum. *Jour. Maryland Acad. Sci.* 1(1): 38-42. 1930.—Aluminum is probably not a constituent of living material, and is therefore not essential to life. On the other hand, aluminum in the diet is not harmful when present in such concentrations as result from the use of aluminum-containing baking powders. —*O. S. Rask.*

9729. **RICE, HUGH A., and ARTHUR H. STEINHAUS.** Studies in the physiology of exercise. V. Acid-base changes in the serum of exercised dogs. *Amer. Jour. Physiol.* 96(3): 529-537. 1931.—From analyses of blood samples drawn from dogs [number not stated] and man before, during, and after various forms of exercise, the following conclusions are drawn: During strenuous exercise on a 22% grade, motor driven treadmill the serum of dog's blood shows a more alkaline pH coincident with reduction in the bicarbonate and CO_2 tension. These changes are related in time and degree to a gradually mounting body temp. Exhaustion in this form of exercise is characterized by alkalosis and overheating. Dogs exercised by swimming in water at temp. of 20° and lower show rising CO_2 tensions, more acid pH and lowering of the bicarbonates of the serum. An otherwise steady body temp. drops below normal as the animal nears the exhaustion point. While swimming at water temp. between 25°-30° C. a minimum of disturbance is noticed in the dog's acid-base balance and body temp. until just before the correspondingly postponed fatigue point is neared. Over-heating without exercise and swimming in water with temp. around 40° C. produce serum changes in dogs' blood similar to those found in treadmill running. The blood changes in man during ergometer exercise though quite opposite to those of the dog exercised by running, parallel closely those of the dog swimming in water at moderate temp. The greatest caution is needed in attempting to translate the results gained from the study of exercised dogs into human physiology unless the differences here described have been given full consideration. Therefore, swimming seems preferable to treadmill running when dogs are used in exercise experiments.—*Authors' summary.*

9730. **ROSSI, ALESSANDRO.** Distribuzione degli elettroliti nel latte e nell'ultrafiltrato. [Distribution of electrolytes in milk and its ultrafiltrate.] *Boll. Soc. Ital. Biol. Sperim.* 5(4): 475-479. 1930.—Up to 60% of the Ca in milk is in non-diffusible form; more than 60% of the P is also in non-diffusible form. 18% of the K is bound to colloids, whereas Cl is completely diffusible. Fresh milk does not differ from pasteurised milk in physico-chemical properties and in distribution of electrolytes; and only slight variations of pH were observed.—*M. Comel.*

9731. **SALTER, WILLIAM T., and JOSEPH C. AUB.** Studies of calcium and phosphorus metabolism. IX. Deposition of calcium in bone in healing scorbutus. *Arch. Path.* 11(3): 380-382. 1 pl. (col.) 1931.—Young adult guinea pigs were fed a diet deficient in vitamin C, the subsequent deposit of bone being marked by intramuscular injection of alizarin red. The animals died in the 4th week unless given orange juice. The results indicated that Ca fails to be deposited in bone when the diet, though adequate in Ca, is deficient in vitamin C. The subsequent addition of vitamin C to such a diet allows Ca to be rapidly deposited. This deposit is largely at the epiphyseal ends of the bone and in the trabeculae; hence the reserve supplies of Ca are involved by the pathologic changes in the bone cells.

9732. **SCHIERONI, CESARE, e GINO VIANELLO.** Il ricambio azotato e minerale nei cani alimentati esclusivamente con carne autoclavata, od integrata con lievito di birra. [N and mineral metabolism of dogs kept on an exclusive diet of autoclaved meat, and with addition of beer yeast.] *Biochim. e Terapia Sperim.* 18(5): 146-169. 1931.—Dogs kept on exclusive autoclaved dog or horse meat developed anatomical and functional lesions of the intestinal tract. The dogs showed a complex of symptoms due to intoxication and avitaminosis, and died after loss of body weight. The N metabolism showed variations only during the terminal stage of the illness; the balance of N being then negative. This was due in part to vomiting. The P and Ca metabolism showed on the contrary an early disturbance. The autoclaved meat with beer yeast added supported the dogs in good condition for a year, the N, P and Ca balances being then positive. The development of intestinal lesions is attributed to the local action on the intestine of toxic products formed in the autoclaved meat. The alleviating effect of yeast is interpreted as a double action: first, supplying partly the vitamin needs, and second, equilibrating the cellular metabolism.—*M. Comel.*

9733. **SCHNITZER, KARL LUDWIG.** Über ein Kalkdepot. *Pflüger's Arch. Ges. Physiol.* 225(5/6): 705-709. 2 fig. 1930.—In an x-ray study of 1064 specimens of *Rana fusca,* 692 ♂ and 372 ♀, from Jan. 1, 1929 to March 15, 1930, no correlation was found between the size of the lime sacks and either sex or season of the year. In an unspecified number of frogs taken in summer, removal of the thymus caused, as shown by x-ray examination, dwindling or almost complete disappearance of the lime sacks, indicating that this structure is a store for Ca for the uses of the general organism.

9734. **SHERMAN, HARTLEY EMBREY, and TSAN CH'ING WANG.** Calcium, iron and magnesium content of 16 Chinese foods. *Philippine Jour. Sci.* 38(1): 81-82. 1929.—The Ca, Fe and Mg content of some dry seeds, green beans, mung beans, wild rice, rape, chrysanthemum, kohlrabi and squash and of the seeds sprouted in hydrant water and in distilled water, are tabulated.

9735. **SMITH, ARTHUR H., and ROBERT V. SCHULTZ.** Effects of diet poor in inorganic salts on certain organs and blood of young rats. *Amer. Jour. Physiol.* 94(1): 107-117. 1930.—The following experimental rations were used: Diet 1, casein 18%, starch 51%, lard 27%, salts 4%; Diet 2, casein 18%, starch 55%, lard 27%; Diet 3, casein 35%, starch 27%, lard 30%, salts 8%; Diet, 4, casein 45%, starch 13%, lard 32%, salts 10%. The plan was to compare measurements and composition of the various organs in the group given the low salt ration with other groups of animals of the same age or body weight but with different nutritive history during the experimental period of 40 days. The "low salt" group, consisting of 26 rats weighing from 41 to 49 gm., was given diet 2 without added salts at weaning and in all but 1 case the body weight was maintained at 45 ± 5 gm. throughout the experimental period. Occasionally the weight of a rat in this group dropped below the 40-gm. limit but administration of the control diet containing salts always raised the weight level above 40 gm. within two days. The "physiological" control group comprising 20 animals was killed and autopsied at weaning when they weighed 40-45 gm. These were normal rats of the same body weight as that maintained in the "low salt" group. The "chronological" control group consisted of 12 rats which had been given diet 1 at weaning and which grew normally on this ration for 40 days. There were thus available normal animals of the same age as that of the experimental group. The "low calorie" control group including 10 rats maintained at the weaning weight of 40 to 45 gm. for the 40-day experimental

period by limiting the quantity of diets 3 and 4 which are so adjusted that, in spite of the decrease in total calories provided when 1 to 2.5 gm. of the food are fed, the absolute quantity of both the indispensable protein and salts is adequate for normal growth of a rat weighing 40-45 gm. At the beginning of the experimental period this group required about 2.5 gm. of food per day and diet 3 was used; later the energy requirement for maintenance of body weight decreased to approximately that furnished by 1 gm. of food and then diet 4 was fed; both rations yield about 5 calories per gm. This group served as a control on the effects of stunting per se, apart from any qualitative deficiency in the ration. The "low salt" splenectomized group comprised 10 rats, splenectomized at weaning and maintained thereafter on diet 2 during the 40-day experimental period. Young rats maintained for 40 days on an experimental ration deficient only in ash do not increase in body weight. The body and tail lengths of such rats at the end of the experimental period are greater than those of normal rats of the same body weight. The leg bones are heavier than those of normal rats of the same weight, the increase being largely accounted for by the higher content of organic residue. The fresh weight of the kidneys of the experimental animals is strikingly greater than that of normal rats of the same weight. The concentration of moisture, ash and organic solids of the kidney is similar to that of normal rats of the same weight rather than age. The fresh weight of the spleen is diminished and this organ is more like that of the normal weight controls than age controls. There is a polycythemia, the cells being smaller than normal and the total hemoglobin of the blood less than normal.

9736. TAYLOR, N. B., and A. FINE. The excretion of calcium through the intestine. *Amer. Jour. Physiol.* 93(2): 544-553. 1930.—Observations on 18 normal cats showed a small but constant excretion of Ca through the small and large intestines. Ca injected into the veins of animals kept upon the usual diet of meat scraps and biscuit practically disappears from the blood within 3 hrs.; this cannot be accounted for by excretion through the bowels or kidneys, and apparently the excess Ca does not leave the body. The excretion of the injected Ca through the large and the small bowels is several times greater in parathyroidectomised than in normal animals. Administration of parathyroid extract was without significant effect upon the excretion of Ca through the bowel during a 6-hr. period.

9737. TELFER, S. V. Mineral metabolism in infancy. III. The substitution of cow's milk for human milk in infant feeding. *Glasgow Med. Jour.* 114(6): 265-284. 1930.—In 5 breast-fed infants 7-11 mos. old a balance experiment was conducted to determine the retention of Ca and Fe immediately before weaning. After a fortnight during which the infants were accustomed to ingest an equivalent amount of undiluted cow's milk sweetened with cane sugar (the intake of Ca, Mg and P being thus quadrupled while the intake of Fe was practically unaltered) the balance experiment was repeated. The percentage retention of the mineral elements was reduced. The amount of the bone-forming elements retained was considerably increased. The amount of Fe retained was markedly diminished. The composition of the feces was widely altered, the percentage of total fat and of all the mineral components except Fe being much increased. The fecal weight was considerably increased.

9738. TOVERUD, KIRSTEN UTHEIM, og GUTTORM TOVERUD. Undersøkelser over mineralstoffskiftet under svangerskap og diegivning, med saerlig henblikk på rakitt- og kariesprofylakse. II. Undersøkelser på hunder. III. Praktisk betydning av de eksperimentelle undersøkelser. [Studies on the mineral metabolism during pregnancy and lactation and its special bearing on the disposition to rickets and dental caries. II. Experiments on dogs. III. Practical application.] *Norsk Mag. Laegevidensk.* 91(1): 53-81. 16 fig.; (3): 286-303. 6 fig. 1930.—Experiments (27) were performed on 9 women in order to study the mineral metabolism of pregnancy and lactation. Total intake and output of Ca, P and Mg were determined for periods of 4 days during the last 2-3 mos. of pregnancy; in 1 woman during the 3rd mo. They were given a common Norwegian diet. Negative Ca and P balances were found in 21 of 27 experiments in pregnancy; the balance could be made positive by increasing the Ca and P intake to a certain level: for Ca to 1.7 gm., for P to 1.6 gm. daily; this was done by giving Ca as a special Ca-lactate preparation and by increasing the quantity of milk in the diet. In a few experiments an addition of cod liver oil to the usual diet without increasing the Ca intake turned the balance in a positive direction, but in the majority of experiments cod liver oil did not affect the negative balance at all. Of the 11 metabolism experiments performed during lactation on 5 women, 5 gave a negative and 6 a positive Ca and P balance. The Ca content of breast milk in 14 lactating women on the same diet was below normal, and could be increased by increasing the Ca intake in the diet. To determine what effect a diet low in Ca, P and vitamins might have on the mother and young, experiments on dogs were started. A bitch was given a diet low in Ca, P and vitamins A and D before and during pregnancy and during lactation. By metabolism experiments on Ca, P and Mg, performed in 3 day periods every week throughout the whole pregnancy, it was found that the bitch suffered a very great loss of Ca (about 10% of its original Ca content). During the lactation period, 8 days after delivery, the mother developed tetany with a serum Ca of 5.15 mgm. per 100 cc. and a serum P of 2.92 mgm. per 100 cc. Chemical analyses of metatarsal bones resected just before and after pregnancy and lactation showed a great loss of Ca and P in the bone resected after the end of lactation. The young which after 6 wks. of lactation were given the same diet as the mother showed very early signs of rickets with marked deformities of the extremities. The rickets in these puppies was more pronounced and appeared earlier than in puppies born and nursed by a mother given the experimental diet from the day of delivery. These last puppies showed a more marked rickets than puppies born and nursed by a mother on a normal ration but given the experimental diet after weaning. Chemical analyses of the bones from these 3 different litters of puppies performed at the same age showed a Ca and P content corresponding to the difference in development of rachitic symptoms. X-ray pictures of the jaws of the puppies revealed a similar difference in tooth calcification and development. Ground specimens of permanent teeth showed the same steps in calcification of enamel as well as of dentin. X-ray pictures taken of the newborn of the experimental bitch revealed no changes from normal; neither did microscopic examination of these bones. By chemical analyses however a lowering was found of Ca and P content of the femur as well as of the whole body. Thus the predisposition to rickets is developed as a result of insufficient nutrition of the mother during pregnancy. The great difference in disposition to rickets and dental caries in cases where the postnatal care has been alike may be explained on the basis of insufficient nutrition of the mother during pregnancy; particularly a low Ca and P and vitamin A and D intake will, during the last 2 months of pregnancy when the calcification of bones and teeth is going on in the fetal organism, predispose the infant to these 2 diseases.—*From authors' summaries.*

9739. WACHSMUTH, W. Über die Blutzuckerregulation bei partieller Leberausschaltung. (Gleichzeitig ein Beitrag zur Frage der Leberfunktionsprüfung.) *Zeitschr. Ges. Exp. Med.* 73(5/6): 659-677. 1930.—It was shown in a previous paper that the curve of increase in glucose concentration in the blood after the giving of glucose is higher and flatter in an Eck-fistula dog than in a normal dog. The alkali reserve of an Eck-fistula dog is normal. The giving of $NaHCO_3$ does not change the form of the alimentary hyperglycemic curve in a normal dog, but it changes that of the Eck-fistula dog to normal.

The Eck-fistula dog has very little resistance to the giving of acids, and it is believed, therefore, that the abnormal glycemic reaction of the Eck-fistula dog is due to the inability of the liver to maintain a proper acid-base equilibrium. There is also a relationship between the response to alimentary hyperglycemia and the amount of pigment estimated in the urine by Hielmeyer's photometric method. This method appears to be of decided value in estimating liver function.—*W. C. Alvarez.*

9741. **WEISER, ISTVÁN, és ARTUR ZAITSCHEK. A jódetetés jelentösége az állattartásban. [Iodine metabolism in milch goats.]** [German summary.] *Kisérletügyi Közlemények [Budapest]* 33(1): 112-117. 1930.—Of a daily average of 37.9 mgm. I fed as KI to 2 milch goats, there was excreted 4.85% in the feces, 34.7% in the urine, and 24.02% in the milk, whilst 36.43% remained in the organism. The average daily milk yield of the 2 goats was practically the same,—1.81 and 1.85 l. The milk from one goat contained 3.82 mgm. I per liter, that from the other 6.25 mgm. per l. The milks of 2 control goats, which received the same feed but without KI, contained 0.025 and 0.026 mgm. I per liter.—*Authors' summary (transl. by E. O. Whittier).*

9742. **WESTERLUND, A. A contribution to the knowledge of Ca-metabolism. II. The relative fecal outgo of Ca in growing pigs fed exclusively on grain products. III. The relative fecal outgo of Ca in dairy cows. IV. The relative fecal outgo of Ca in children.** *Skand. Arch. Physiol.* 60(1/4): 204-220; (5/6): 251-263; 264-272. 1930.—II. A study of the relative fecal outgo of Ca in its dependence on certain experimental factors, viz. Ca-Si-ratio, Ca-fat-ratio, body weight of experimental animals, Ca-P-ratio, Ca-Mg-ratio, K-Na-ratio, relationship of inorganic base equivalents to acid ones in the food ash, and Ca-consumption. The experimental data of the present investigation are those which have been obtained by E. B. Forbes and co-workers (1921) in a series of 35 mineral balances of growing pigs. Assuming that the variations of Ca-consumption have no traceable influences, Westerlund concludes that limiting factors for the utilization of Ca in the experiments analyzed, are a deficiency of Na, P, fat and basic equivalents, and an excess of Si in the food of the animals. III. The object was to learn how a series of different factors affect the "disposal" of catabolized Ca, given numerically by the values of the relative fecal outgo of Ca, by computing net regression coefficients referring to the separate covariations of these factors and the relative outgo. Westerlund concludes that the difficulty in keeping lactating cows in Ca equilibrium on the feeds used is chiefly due to unsuitable values of those factors which have proved to be important controllers of Ca disposal. Among these controlling factors there are dietary constituents (Ca, P, fat, silage and Na), the average supply of which has been too scanty to guarantee the animals a maximum utilization of Ca. On the other hand, other food constituents (Si and Mg) were too plentiful in proportion to the Ca consumed. Controllers of an internal kind belong here also, such as the milk yield. The analysis has shown that the more copious the milk flow, the smaller the relative fecal outgo of Ca, other factors being equal. IV. This paper deals with material from Ca balance determinations of 6 young boys. The object was to learn how a series of different factors affect the fecal outgo of Ca. Westerlund concludes that the value of the relative fecal outgo of Ca has been reduced if the consumption of K, Mg and fat has been more restricted, and that of P more liberal than has been the case, other factors being unchanged. Also, it is concluded, that a use of Ca, more restricted than the average, would reduce the relative value of the fecal output but increase the absolute value of the difference between income and absolute fecal outgo, other factors being equal, thus reducing Ca retention.

9743. **WHEELON, HOMER. Geographical factor in calcium metabolism.** *Endocrinology* 13(4): 363-366. 1929.—425 partially selected young adults showed average blood Ca 10.34 mgm. %; extremes 4.0-16.6. Normal limits should be 8.5-12.4 mgm. %. 19, or 50%, of his series below 8.5 mgm. were clinically diagnosed spasmophilia. Water analysis of 2 rivers in Washington state showed average 11.2 parts Ca per million parts against 81 parts per million for 16 rivers of Missouri river basin. Western slope land and foodstuffs of the Cascade Mountains are deficient in lime. The deficiency of Ca in the Puget Sound Basin of Washington may be compared with the I deficiency in goitre regions and the disturbed Ca metabolism of that region may have its etiology in geographical factors.—*L. Gunther.*

9745. **WU, J. H. Thymus-Milz-Implantation und Kalkstoffwechsel beim Kaninchen.** *Jahrb. Kinderheilk.* 129(1/2): 88-97. 1930.—In 8 experiments with young rabbits a distinctly greater drop in serum Ca showed in 7, after implantation of spleen and thymus, than after the control implantation of liver or kidney. The 3 youngest animals showed a greater reaction from the spleen-thymus implantation (1 death from tetany) than the half grown. This series of implantation experiments gave no proof of phosphorus lowering.—*Author's summary (transl. by O. D. Abbott).*

VITAMINS

9746. **SAIKI, SANETOSHI. On the liver function of animals fed on vitamin-deficient diets.** *Acta Scholae Med. Univ. Imp. Kyoto.* 12(2): 157-175. 1929.—Matsuo's chromodiagnostic method of studying liver function, consisting of intravenous injections of dye and subsequent measurement of the amount excreted in the bile, was applied to animals on vitamin-deficient diets. Vitamin C-deficient guinea pigs exhibited a greatly increased capacity and a tendency toward increased ability for dye excretion from the liver, indicating that vitamin C may control liver function. Vitamin B-deficient fowls showed decreased capacity for liver excretion. Vitamin A-deficient rats showed a marked decrease in the excretory capacity of the liver, while vitamin A-deficient monkeys showed a decrease in both capacity and ability. The functional disturbance was much greater in A-deficient than in B-deficient animals.—*M. Collins.*

ANIMAL PHYSIOLOGY

DIGESTIVE SYSTEM AND DIGESTIVE SECRETIONS

9747. **APPERLY, FRANK L., and JOAN H. NORRIS. The automatic regulation of gastric acidity.** *Jour. Physiol.* 70(2): 158-168. 1930.—Dilute HCl (250 cc.), mixed with some indifferent substances which could easily be estimated, was placed in the empty stomach of fasting subjects. The strength of acid employed varied from 0.080 N to 0.128 N and the indifferent substance varied also in different cases, the substances

being glucose, phenol-sulphone-phthalein dye, urea, or ferric chloride. In all, 57 people were examined by this method, 22 healthy students, 24 hospital patients with no gastric symptoms, and 11 dyspeptics. The authors conclude that when acid above a certain concentration enters the normal stomach, whether secreted or artificially placed there, in most cases the concentration is reduced mainly by dilution, but partly by neutralization. The diluting fluid is derived partly from the gastric wall and partly from the duodenal fluids. In a few cases no alkali appears in the duodenal fluids, and in a few others gastric acid is secreted even in the presence of a foreign acid. There was evidence of early duodenal regurgitation in 72% of 46 cases examined.

9748. BALL, ERIC G. The composition of pancreatic juice and blood serum as influenced by the injection of acid and base. *Jour. Biol. Chem.* 86(2): 433-448. 1930.—The pH of the juice varies with its rate of flow. Juices secreted rapidly are the more alkaline, containing large amounts of bicarbonate and small amounts of chloride. In slowly secreted juices a lower alkalinity is found with large concentrations of chloride and small concentrations of bicarbonate. The sum of the bicarbonate and chloride concentrations is nearly constant regardless of the rate of flow. Intravenous injections of HCl cause but little change in the pH of pancreatic juice, regardless of the effect on the serum. Lowered bicarbonate values for serum are manifested quantitatively though not proportionally in the juice. Intravenous injections of sodium carbonate solution, causing an alkaline swing in the serum, produce remarkably little change in the reaction of the juice. However, the increased concentration of bicarbonate and sodium in the serum appears quantitatively in the juice. The possible significance of these findings and their relation to other studies of a similar nature is discussed.—*Author's summary.*

9749. BALL, ERIC G. The composition of pancreatic juice and blood serum as influenced by the injection of inorganic salts. *Jour. Biol. Chem.* 86(2): 449-462. 1930.—Pancreatic juice and blood serum have identical osmotic pressures. Concentrations of Na and K expressed per kgm. H_2O are similar in the 2 fluids. The injection of these ions into the blood stream increases their concentrations in both fluids to the same degree. It is therefore concluded that the pancreatic tissue is freely permeable to Na and K. Calcium, Mg, and phosphate were found in pancreatic juice in concentrations 1/20-1/4 those in blood serum. The intravenous injection of salts yielding these ions in amounts sufficient to increase greatly their concentrations in the serum caused but little increase in their concentrations in the juice. It is concluded that the pancreas is but slightly permeable to Ca, Mg, and phosphate ions. The concentration of total organic matter in the juice appears to depend upon the state of activity of the gland previous to the secretion of the juice.—*Author's summary.*

9750. BAXTER, HAMILTON. The composition of the saliva in different phases of the secretion and by repeated stimulation. *Amer. Jour. Physiol.* 91(1): 132-142. 1929.—The parotid saliva of a dog with a permanent salivary fistula secreted during stimulation varied in composition from that of the different phases of the after-flow. The percentage of organic matter in parotid saliva obtained by different stimuli was higher in the 2nd min. after-flow than in the secretion collected during the 1st min. of feeding. The organic and inorganic content of the after-flow of the successive 5 min. was greatly reduced. The content of organic substances in the parotid saliva of the 2nd feeding was greater only when the interval between the 1st and 2nd feeding was less than 1 min. There was no exact proportionality between the amount of organic substances in the dog's submaxillary saliva and its viscosity. Certain improved methods of determining the organic and salt fraction were employed.—*Author's summary.*

9751. BAXTER, HAMILTON. Changes in composition of parotid saliva in the dog after section of the sympathetic nerve in the neck and after extirpation of the superior cervical sympathetic ganglion. *Trans. Roy. Soc. Canada, Sect. 5, Biol. Sci.* 24(1): 207-211. 1930.—In normal dogs with permanent salivary fistulae, saliva secreted after stimulation with bread and meat powder, HCl, etc., was studied before and after section of the sympathetic. The author concludes: "That trophic impulses (in Heidenhain's sense) as well as secretory impulses are transmitted from the central nervous system through the parasympathetic innervation. The sympathetic nerve supplies the salivary glands with vasoconstrictors. There are probably a few secretory fibres but these play a negligible part in normal conditions because the amount of saliva secreted from any stimulus was practically the same after section of the sympathetic nerve. It seems probable that the sympathetic nerves send special motor fibres to the salivary glands which press out their contents. These data permit a provisional classification of the fibres in the parasympathetic and sympathetic nerves to the salivary glands, adopted by the author's laboratory. Parasympathetic: (1) Secretory, (2) Trophic, (3) Vasodilator. Sympathetic: (1) Secretory, (2) Motor, (3) Vasoconstrictor."

9752. BAXTER, STEWART G. Pancreatic secretion in rabbits. *Trans. Roy. Soc. Canada, Sect. 5, Biol. Sci.* 24(1): 213-215. 1930.—There is a long-continued secretion in the rabbit, with uniform enzyme content which is continuous after the pylorus and bile duct are tied. It is increased by injection of HCl, and especially a mixture of acid, peptone and bile. Removal of the whole gastro-intestinal tract does not abolish the spontaneous secretion. The vagus in the rabbit has the same action as in other animals and contains secretory, trophic and inhibitory fibres.—*Author's summary.*

9753. BLISS, THEODORE L. The acid-base composition of gastric juice during the secretory cycle. *Ann. Internal Med.* 3(8): 838-849. 1930.—Gastric secretion was collected from two healthy laboratory workers, one patient, and a dog with a Pavlov pouch. The fasting juice was collected and then histamin was given. Study was made of the amount of acid, chlorides, total base, Na, K and Ca. During the secretory cycle the concentration of base varies inversely as the concentration of acid. Sodium seemed to be the most important of the individual bases, both in regard to the amount and the way in which it varied during the secretory cycle. The concentration of K was 3-5 times greater in the gastric juice than in the blood serum. The concentration of the other ions studied was less in the gastric juice than in the blood.—*W. C. Alvarez.*

9754. BROWN, G. L., B. A. McSWINEY, and W. J. WADGE. The sympathetic innervation of the stomach. I. The effect on the stomach of stimulation of the thoracic sympathetic trunk. *Jour. Physiol.* 70(3): 253-260. 1930.—In spinal and decerebrate cats and dogs the stomach was divided at the incisura, and records were made of the effects of stimulation of the thoracic sympathetic trunk upon the movements of the stomach. The effects on the stomach depended on the type of stimulation employed. Stimulation at a frequency of 1 per sec. caused contraction of the body of the stomach, while stimulation with a tetanizing current brought about relaxation. The movements of the cat's pyloric antrum were inhibited by all forms of stimulation. The antrum of the dog, although usually inhibited, occasionally showed an augmentor response to sympathetic stimulation. The motor responses were abolished by ergotoxine. Adrenaline did not reproduce the effects of sympathetic stimulation, an inhibition of both parts of the stomach being the invariable result of injection of the drug.—*Authors' summary.*

9755. BRUNTON, CHARLES E., and M. C. G. ISRAËLS. Interrelations of respiration and gastric secretion. *Jour. Physiol.* 70(2): 184-194. 1930.—The authors deal with two questions only: (1) Assuming that the alveolar CO_2 tension rises during gastric secretion, is there a reduction of min. vol. of expired CO_2 and of pulmonary ventilation to allow for a parallel

retention of CO_2? (2) Does the tension of CO_2 in the alveolar air vary as described during the secretion of acid by the stomach, the secretion being produced in various ways? Three forms of gastric stimulation were used: ordinary meals, test meals (Ewald and gruel) and drugs (caffeine and histamine). 1. Results show clearly that, whatever the effect of gastric secretion on the blood, the loss of acid into the stomach does not decrease the volume of expired air, or the volume of CO_2 expired per min. In 23 experiments (9 normal meals, 5 test meals, 9 with drugs), 3 showed decreases of pulmonary ventilation after the meal. In 13 experiments (5 normal meals, 8 with drugs) 1 showed a decrease of min. excretion of CO_2 (obtained from the 10-min. samples) concurrently with gastric acid secretion. 2. Of 20 experiments (9 normal meals, 4 test meals, 7 with drugs), 8 showed a rise of alveolar CO_2 tension after the meal; the rise reached its maximum in about 90 min. No subsequent fall was regularly found, even after 2 hrs. In 3 experiments where water was administered, 1 showed a rise of alveolar CO_2 tension. The pulmonary ventilation was found to increase with meals, but not when drugs were used. Similar changes were observed in the min. excretion of CO_2. No constant rise of alveolar CO_2 tension concurrent with, or varying pari passu with, gastric acid secretion was found. No fall of alveolar CO_2 tension was found after meals concurrent with possible pancreatic secretion, even up to 2 hrs. after. It is argued that any possible excess of alkali resulting from the secretion of volumes of acid normally produced might be expected to be dealt with without necessarily causing a measurable rise in alveolar CO_2 tension. The authors believe that the use of the changes in alveolar CO_2 tension after meals as an indication of the activity of gastric acid or pancreatic secretion is unjustifiable.

9756. CARLSON, H. A., H. J. DVORAK, F. W. LYNCH, C. BORMAN, and O. H. WANGENSTEEN. Value of X-ray evidence of bowel obstruction in various states of intestinal stasis. *Proc. Soc. Exp. Biol. & Med.* 28(3): 343-344. 1930.—"Although x-ray evidence of gaseous distention is an early and valuable sign of simple intestinal obstruction it is distinctly of less value in strangulation obstruction or in stasis due to mesenteric vein occlusion. Gas shadows are also observed early as a rule in peritonitis."

9757. CORBEILLE, CATHERINE. Changes in volume of the kidney in response to acoustic stimulation. *Amer. Jour. Physiol.* 91(2): 507-512. 1930.—The method and the experimental conditions were the same as in the previously reported experiments on the spleen. Simultaneous tracings were made of the responses of the kidney and the spleen (in dogs) to acoustic stimulation. The kidney responses followed definite types dependent on the mode of stimulation: sudden contraction with the onset of stimuli, slow contractions during the continuance of the stimuli, sudden contractions at the cessation of the stimuli, slow contractions after cessation of the stimuli and delayed contractions and dilatations. In the animals in which simultaneous observations were made of both kidney and spleen it is noted that the responses do not always parallel each other, but occur sometimes independently in one organ or the other, sometimes in the same direction in both organs and sometimes simultaneously but in opposite directions. The anatomic possibilities for the origin and paths of the visceral acoustic reflexes are discussed briefly.—*Author's summary.*

9758. DAVIES, DANIEL T., and T. G. ILLTYD JAMES. An investigation into the gastric secretion of a hundred normal persons over the age of sixty. *Quart. Jour. Med.* 24(93): 1-14. 1930.—Of 100 persons aged 60-95 yrs., 43 showed a normal secretion of HCl, 13 a hypersecretion, 12 a diminished secretion, and 32 no free HCl. Small volumes of juice and an inhibition of secretion during the first 1-1½ hrs. were common findings. Achlorhydria, by the use of histamine, could be divided again into as many apparent as true, true achlorhydria being about 15%. The ferment content of the gastric juices varied in the majority, and bore little relationship to HCl secretion. In none of the cases of achlorhydria was pepsin completely absent. Histamine stimulated pepsin production in addition to HCl secretion. Pepsin secretion occurred in the absence of demonstrable HCl secretion, but no case was encountered possessing free HCl without pepsin. The secretion of HCl appears to be more susceptible to outside factors than that of pepsin, in that it is more easily inhibited or more quickly deranged. Anemia was more commonly found in those possessing a diminished gastric secretion than in those with abundant secretion. Anemia, though slight in degree and indeterminate in type, was more common in those possessing a low ferment content of the gastric juice than in those with a high ferment content. Atrophic changes of the mucous membrane of the tongue were more frequent in those cases showing a diminished secretion of gastric juice than in those with a normal secretion.—*Author's summary.*

9759. DUTHIE, R. J. The action of histamine on the chloride content of the stomach. *Quart. Jour. Med.* 23(92): 447-449. 1930.—The stomach contents of 14 patients were examined both before and after the subcutaneous injection of 0.25 mgm. of histamine. There was an increase in total chloride concentration in all 14 cases, with no evidence of duodenal regurgitation, indicating that regulation of acidity occurs in the stomach. In 8 cases the increase in total chloride was less than the increase in chloride that could be accounted for by the increased acidity, the change in proportion of HCl and the neutral chloride in the gastric secretion apparently resulting from the action of histamine in stimulating the secretion of the Cl ion as HCl and diminishing the secretion of the ion as neutral chloride. In other words, the increase in HCl after histamine injections takes place at the expense of neutral chloride.

9760. EURA, SHIGENARI. Studien über die Muskulatur des Ösophagus verschiedener Tiere. *Japanese Jour. Med. Sci. III. Biophys.* 1(1): 1-51. 28 fig. 1927.—Spontaneous movements, action of drugs and reaction to electrical stimulation were studied in muscle strips and in the entire esophagus. The esophageal wall contains different proportions of smooth and striated muscle in the cat, dog, rabbit, guinea-pig and domestic fowl; smooth muscle alone in frog and turtle, striated muscle in the eel. Those parts of the organ containing only striated muscle, after removal of the mucosa, show no spontaneous movements, even if Auerbach's plexus is present. At places where spontaneous movements occur there is always found smooth muscle, and the magnitude of the movement is proportional to the amount of smooth muscle. Such movements persist after removing almost all of Auerbach's and Meissner's plexuses and all nerve cells from the smooth musculature, hence they appear to be independent of nerve cells and plexuses. The cross-striated muscle of the esophagus is as insensible to adrenalin, pilocarpine, atropine, nicotine, acetyl-choline and Ba as skeletal muscle. The smooth muscles, however, are very sensitive to these drugs, as are those of the intestinal tract. Adrenalin acts, as on the intestine, to inhibit the smooth muscle of the esophagus or the entire organ in the guinea-pig, rabbit, hen, frog and turtle, but it stimulates the smooth muscle parts of the esophagus in the dog and cat. The cross-striated musculature reacts to induction shocks as does skeletal muscle, giving twitches with single and tetanus with rapidly repeated shocks. Latency and duration of twitch are similar to those of skeletal muscle. A part of the esophagus containing smooth and striated muscle together reacts to single shocks diversely according to the relative amount of each kind of muscle; and in general two forms of contraction can be distinguished, one rapid due to striated muscle, the other slower as for smooth muscle. The esophageal striated muscle does not differ materially from skeletal; and the smooth muscle shows spontaneous movements,

and reacts to drugs and electric shocks in the main, like the smooth muscle of the intestine.—*H. S. Hopkins.*

9761. **FAULEY, GORDON B., and A. C. IVY.** The effect of exclusion of pancreatic juice on gastric digestion. *Amer. Jour. Physiol.* 89(2): 428-437. 1929.—Ligation of the pancreatic ducts in 7 Pavlov pouch dogs decreased gastric secretion for a few days, followed in most cases by a hypernormal secretion (due to an unexplained increase in the intestinal phase of gastric secretion) sometimes persisting as long as 6 mos., or declining to normal in 3 or 4 wks. Alkalies increased the secretion in 2 dogs and had no effect in 2 others. The emptying time of the stomach was decreased by ligation of the pancreatic ducts (4 dogs), but more decreased by total pancreatectomy (4 dogs). It is believed that hunger, or polyphagia, is the factor principally concerned in the causation of this decrease. The decrease in emptying time following ligation of the pancreatic ducts or pancreatectomy shows that acidity of the duodenum as a controlling factor of the rate of emptying of the stomach is very minor in importance when compared to the hunger, or polyphagia factor, or other unknown factors.

9762. **FITZHUGH, GREENE, MILTON L. MILLER, GRANTLEY W. TAYLOR, and JOSEPH C. AUB.** Studies of calcium and phosphorus metabolism. XB. The effect of intravenous calcium chloride on peristalsis following intestinal obstruction in dogs. *Amer. Jour. Physiol.* 97(1): 142-145. 1931.—In observations on dogs, including effect on simple intestinal obstruction, on the stimulating effect of eserine, and on the production of chronic Pb intoxication, no demonstrable change in either peristalsis or intestinal muscle tone could be seen after the intravenous injection of small or large doses of $CaCl_2$.

9763. **FLOREY, H.** The secretion of mucus by the colon. *British Jour. Exp. Path.* 11: 348-361. 1930.—In cats and dogs, stimulation of the nervi erigentes over a short space of time does not cause any detectable secretion of mucus from the intestine. In the great majority of experiments no secretion occurs after stimulation for prolonged periods. In one case quantities of mucus at last appeared. If the nerve supply does influence secretion it is only after the most prolonged stimulation. Experiments with pilocarpine support this. A single large dose causes inappreciable colonic secretion and it is only after repeated doses acting over a long time that any is caused. It is improbable that pilocarpine causes mucus secretion by stimulating nerve endings. Other evidence is offered against any effective nervous control of the goblet-cells of the colon:—(a) Secretion of mucus goes on in apparently normal fashion after section of all extrinsic nerves. (b) The secretion of mucus in a Thiry fistula of the colon is small and appears to occur at a constant rate. (c) Tissue cultures from chicken gut show that goblet-cells develop and produce mucus which is discharged. Here no organised nerves are present. (d) Histologically nerve cells have never been demonstrated to serve goblet-cells. Application of agents capable of causing cell damage calls forth a secretion from the goblet-cells of the colon. This might be caused either by direct action of the noxious agents on the goblet-cells or by the liberation of some chemical substance which stimulates them. Tests with histamine, acetyl choline, adenosine and peptone solutions failed to show stimulation of mucus secretion from goblet-cells. Extracts of colonic mucosa did not have any observable effect. It appears therefore that goblet-cells directly react to the insult of the noxious agent.—*J. Bland.*

9766. **GOLDSTEIN, BORIS.** Zur Physiologie des isolierten Pankreas. II. Über die fermentbildenden und sekretorischen Prozesse im isolierten Pankreas. *Zeitschr. Ges. Exp. Med.* 65(3/4): 411-426. 2 fig. 1929.—Ferment formation and secretory processes in the pancreas are independent. The principal stimulus to ferment formation comes through the vagus. The principal stimulus for secretion is secretin. The secretion of pancreatic juice following stimulation of the vagus is to be looked on as a process secondary to the formation of ferment. Parallel studies were made of the external secretion of the isolated pancreas and the amount of ferment which goes into the Ringer solution perfused through the vessels.—*W. C. Alvarez.*

9767. **GREENE, CARL H., WALTMAN WALTERS, and CLYDE H. FREDRICKSON.** The composition of the bile following the relief of biliary obstruction. *Jour. Clin. Investigation* 9(2): 295-310. 1930.—The composition of the bile following the relief of biliary obstruction was studied in 9 cases. The total daily output of bilirubin was more or less constant and was not related to the other factors studied. The concentration varied inversely with the volume of the bile. One or 2 patients showed some evidence of a washing out of retained pigment, but if this occurred in all it took place so slowly as not to be apparent in observations of short duration. Biliary obstruction inhibits the formation of bile acids. If the liver is not too greatly injured there is a relatively rapid return to normal; otherwise the return is greatly delayed. This was true both with regard to the concentration and total amount of bile acids. The concentration of chlorides in the bile is slightly greater than that in the blood serum. With cholerrhagia, the resultant loss of salts becomes so great as to be of clinical significance. The loss of fluids by this channel may also be so great as to cause diminution in the output of urine. The concentration of urea in the bile apparently varies directly with that in the blood. Ordinarily this pathway of elimination is not significant, but in 1 case there was considerable loss of urea through the fistula.—*Authors' summary.*

9768. **HARTZELL, JOHN B.** The effect of section of the vagus nerves on gastric acidity. *Amer. Jour. Physiol.* 91(1): 161-171. 1929.—Experimental work on the effect on gastric acidity of section of the vagus nerves has been largely inconclusive for 3 reasons: (1) the preoperative normal state has not been adequately determined; (2) the observations often were made on animals that had been operated on for the production of fistulas and pouches, and (3) the period of postoperative observations has been too brief. The present study, which was carried out on 8 dogs, is concerned only with the effect of section of the vagus nerves on the degree of acidity of the gastric content during that portion of the normal digestive cycle which begins with the ingestion of a meal and which ends when the stomach is empty. It was found necessary to train each animal for 1-6 wks. in order to have it thoroughly accustomed to the procedure. In the beginning, any psychic upset, even intubation, was sufficient to cause a marked decrease in acidity. Only at the end of the period of training did the acidity begin to show a uniform curve. Section of the vagus nerves then was performed. In some experiments the large anterior and posterior vagal trunks were cut just above the diaphragm; in others, the vagal branches were cut in the abdomen, care being taken to cut the pyloroduodenal nerve which descends from the vagal branch to the liver. In those dogs in which the vagus nerves were sectioned in the thorax, there was marked reduction in both free and total acidity, and the highest postoperative curve was lower than the lowest preoperative curve. There was 1 exception: in 1 animal the concentration after operation was the same as before, and at necropsy it

was found that the posterior vagal trunk had been missed. In those animals in which the branches of the vagus nerves were cut in the abdomen the amount of free HCl occasionally continued to rise to the same height as before operation. However, the secretory curve was shorter, so that the stomach was empty of all food and gastric juice 1-2 hrs. sooner than before operation.—*Author's summary.*

Über den Einfluss von gallenaustreibenden Substanzen auf die Funktionen der Gallenblase und des Oddischen Muskels.** *Nagoya Jour. Med. Sci.* 5(2): 75-78. 1931.—Administration of such substances as egg yolk (2 experiments on dogs cited) led to a primary reflex contraction of the gallbladder and bile duct, and a secondary pressure of excreted bile and relaxation of the sphincter of Oddi.

9770. **HOBSON, R. P. Studies on the nutrition of blowfly larvae. I. Structure and function of the alimentary tract.** *Jour. Exp. Biol.* 8: 109-123. 1931.—The mid-gut in *Lucilia* can be divided into 3 distinct regions. Histologically the anterior and posterior segments are similar. In a feeding larva the cells are highly vacuolated and contain fat; in a starved larva the cells are deeply staining and non-vacuolated. In the middle segment the cells are always deeply staining and free from vacuoles and fat, whatever the state of nutrition. The pH varies along the gut and with the nature of the food. It is on the acid side in the middle segment and on the alkaline side in the other segments. It is suggested that the acidity in the middle segment may be due to an acid secretion, the most likely component being phosphoric acid. The alkaline reaction in other parts of the gut is probably caused by ammonia. Tryptase, peptidase and lipase are present in the mid-gut, the enzymes being concentrated in the anterior and posterior segments. Carbohydrate splitting enzymes are absent except for a feeble secretion of amylase in the salivary gland. It is suggested that food is stored unchanged in the crop and, passing into the mid-gut, is rapidly forced into the middle segment. Some absorption of water and simple products of bacterial action occurs along the anterior segment, the concentration of the food being completed in the middle segment where the acidity prevents digestion. The food then passes into the posterior segment, dissolves in the alkaline fluid and is digested and absorbed.—*J. M. Robson.*

Gén.* 28 (4): 822-832. 4 fig. 1930.—By x-ray photograms from different angles, the volume of the empty and the full stomach has been calculated. Average values are: (1) resting capacity, 850-1000 cc. (2) maximal capacity, 1500-1800 cc. The pressure at the cardiac region can vary from 0 to 12 cm. of water which indicates the force that may be developed by the contracting esophagus.—*W. R. Fearon.*

9774. **JOHNSTON, CHARLES G., and ERIC G. BALL. Variations in inorganic constituents of the pancreatic juice during constant drainage of the pancreatic ducts.** *Jour. Biol. Chem.* 86(2): 643-653. 1930.—A study of pancreatic juice excreted by 5 dogs with permanent pancreatic fistulae reveals a marked variation in the concentrations of Cl, bicarbonate, and Ca. The concentrations of Cl and Ca decreased as drainage progressed. With the fall in Cl the bicarbonate concentration in the juice rose, the total anion concentration remaining nearly constant. The total cation concentration closely paralleled the anion concentration. The pH of the pancreatic juice varied between 7.16 and 8.04.—*Authors' summary.*

9775. **JUNG, FREDERIC T. Effects of ligating the bile duct in the rat.** *Proc. Soc. Exp. Biol. & Med.* 27(5): 362-364. 1930.—Ligation of the bile duct in ♂ white rats was followed in 12 hrs. by appearance of a yellow color in urine and a yellow tint in the ears. No gross changes were found in the teeth, nor were such changes found in the teeth of 5 rats simultaneously ligated and thyroparathyroidectomized.

9776. **KIRSTNER, A., und S. LURJE. Über den Einfluss von Hochfrequenzströmen auf die sekretorische und evakuatorische Magenfunktion.** *Arch. Verdauungskrankh.* 48(5/6): 366-382. 1930.—Observations were made on 36 patients with different functional (secretion and evacuation states) of the stomach. In normal and hypersecretion, the secretion of the stomach was reduced under the influence of diathermy. In hyposecretion, diathermy exerted no marked influence on secretion. The evacuation of the stomach was accelerated in all secretion-types; this was clearly demonstrated where the evacuation before diathermy was slow. Under the influence of diathermy the different disorders of the stomach disappeared quickly. The influence of diathermy depends not only on the heating action but also on the specific action of high frequency currents (electrical effect). An essential preliminary condition of the healing effects of diathermy is the proper placing of the electrode over the gastric region.—*Authors' summary (transl. by K. W. Buchwald).*

9777. **KITAKOJI, YOSHIHARU. Studien über die Funktionen der Gallenblase und des Oddischen Muskels in Bezug auf die Absonderung der Blasengalle. I. Über den Einfluss von Nervengiften auf die Funktionen der Gallenblase und des Oddischen Muskels. II. Über den Einfluss von faradischen Nervenreizungen auf die Funktionen der Gallenblase und des Oddischen Muskels.** *Nagoya Jour. Med. Sci.* 5(1): 24-29, 30-33. 2 fig. 1930.—I. Apparatus for studying the functions of the gall bladder and the sphincter of Oddi simultaneously in the living subject by a modified Reach method the isolated sphincter of Oddi by a modified Terasaka method, and the isolated surviving gall bladder by a modified Ishiyama method, are described. Muscarine, acetylcholine, pilocarpine, physostigmin increased the tonus and produced contractions both of the sphincter of Oddi and of the gall bladder, isolated and in the living animal. Atropine and scopolamine relaxed both the sphincter and the bladder; atropine acted more powerfully than scopolamine on the sphincter in the living animal, more weakly on the isolated sphincter. Epinephrine produced no consistent effect on the sphincter; it relaxed the walls of the gall bladder. Nicotine and morphine contracted the sphincter of Oddi. They produced no contraction in the gall bladder in the living subject, but raised the tonus in the isolated gall bladder. II. Stimulation of the intact vagus, or of the peripheral stump of one side after unilateral or bilateral section, almost invariably produced contraction of the gall bladder, with contraction of the sphincter of Oddi and consequent decrease or cessation of discharge. Stimulation of the peripheral stump of the sympathetic nerve produced relaxation of the gall bladder and of the sphincter of Oddi. These effects show that the gall bladder and sphincter of Oddi, like the intestine, are influenced by the sympathetic and parasympathetic systems.

9780. **KRIMBERG, EUGENIE. Über die autosekretorische Eigenschaft des Magensaftes.** *Pflüger's Arch. Ges. Physiol.* 226(6): 816-818. 1931.—The author states that he has performed experiments which show that a phosphotungstic precipitate of gastric juice, when redissolved and injected into dogs, leads to an increased rate of secretion of gastric juice. Essential details of these experiments are not reported.—*M. H. Friedman.*

9781. **LOCKEMANN, GEORG, und WERNER ULRICH. Ueber die Bedeutung des Rhodangehaltes des Magensaftes.** *Deutsche Med. Wochenschr.* 56(45): 1900-1920. 1930.—To ascertain whether the small sulphocyanate content of the gastric juice has any germicidal action, the effect of solutions of HCl in 0.01, 0.02 and 0.1 N strength (representing the varying acidity of the stomach) was tested on *Bacterium coli*, both alone and with 3 different additions of NaSCN in 0.0001, 0.001 and 0.01 N strength, at 18° and 37°. The 0.02 N solutions of HCl, which came nearest the acidity of the normal stomach, required 1½ hrs. at 18° to kill the bacteria without reenforcement; with addition of NaSCN of 0.0001 N, the time required fell to 5 min.; NaSCN of 0.001 N reduced the time to 45 sec., and NaSCN of 0.01 N made it 10 sec. At the temp. of 37° and at the other acid strengths the addition of NaSCN likewise reduced the sterilizing time. Tests of 60 gastric and duodenal juices showed that even such slight traces as 0.0012% and 0.0163% NaSCN, with the free H ions of the gastric juice, may exercise a high germicidal power, thus explaining the general sterility of the gastric contents at their entry into the duodenum.

9782. **[LUR'E, G. S., and B. A. TEMPER.] ЛУРЬЕ, Г. С., и Б. А. ТЕМПЕР. К вопросу о влиянии катионов на желудочную секрецию.** [Influence of cations on gastric secretion.] [German summary.] Одеський Медичний Журнал. (*Odessaer Med. Zeitschr.*) 5(3/5): 261-264. 1930.—Experiments were conducted on patients and healthy subjects (19 in all). Contents were extracted from the fasting stomach, and then every 10 min. after the test-breakfast, consisting of 300 cc. distilled water, with a trace of caffein and methylene blue. Following conclusions were reached: intravenous injection of 5 cc. of 10% solution of $MgSO_4$ augments both general acidity and free HCl. Hyperacid cases show greater increase of acidity than the hypoacid ones. In 3 cases of achylia, $MgSO_4$ exerted no influence.—*B. Van Rosen.*

9783. **MacARTHUR, EDITH H. Fat metabolism. 1. A study of the rate of digestion of fats as determined by the chylomicrons of the blood.** *Jour. Biol. Chem.* 87(2): 299-305. 1930.—The subjects on which the studies were based were healthy white rats and college women in good physical condition, who were without food for 12-15 hrs. preceding the experimental period. The rate of digestion was determined by counting the chylomicrons in the blood using the dark field microscope. Butter from cow milk was absorbed faster than butter from goat milk or butter from cow milk when eaten with bran.—*E. H. MacArthur.*

9784. **McCANN, JAMES C. Studies on the control of the acidity of the gastric juice.** *Amer. Jour. Physiol.* 89(3): 483-496. 1 fig. 1929.—The author devised a method for doing fractional gastric analysis on the normal dog. Histamine and a test-meal of meat and water were used to stimulate the secretion of acid. The uniformity of the results gave value to the method. In the 1st stages, 7 dogs underwent surgical duodenal drainage whereby all the duodenal alkalis were shunted away from the pylorus into the distal portion of the ileum. Post-operative fractional analysis did not show variations from the curves found before operation so far as they represented the chemistry of digestion, or the control of the acidity of the juice. The addition of carbohydrate and fat to the protein meal showed the same alterations of the curves from a meal of meat and water in normal dogs and in operated dogs. The final control of the acid was not altered. Regurgitation of the duodenal alkalis is not, therefore, the essential mechanism for controlling the acidity of the gastric juice, but is probably an associated phenomenon. The results showed that after the acid has stopped combining with the food, the mechanism for controlling the acidity of the juice consists probably of 2 factors capable of bringing the juice to complete neutralization: (1) a gradual reduction of an established high rate of secretion of the acid to a low rate; (2) the capacity of the constant basal secretion of mucus to combine with a constant fraction of the changing volume of acid secreted. This mucus is probably derived from the adjacent mucus-secreting glands in the fundus. When the rate of secretion of acid has fallen to the low basal rate of the resting stomach, the amt. secreted apparently is so small that it completely combines with the basal mucous secretion, giving a combined acid and a neutral (base) chloride.—*Author's summary.*

9785. **McCANN, JAMES C. Studies on the emptying of the stomach.** *Amer. Jour. Physiol.* 89(3): 497-507. 3 fig. 1929.—Normal dogs (no. not stated) were used in 2 series of studies. In the 1st series x-ray examinations of the stomach were made to determine the rate of emptying and the type of motor activity at different times in the course of digestion. In the 2nd series, the influence of certain factors associated with the process of emptying, namely, free HCl, fluidity, and products of digestion, was investigated to determine whether any one of them might be the essential factor which controlled the emptying of the stomach. Combined use of fractional analysis and of roentgenograms has allowed close correlation between the changes in the motor activity of the stomach and the parallel changes in the chemical status of the gastric contents. It has permitted a comparative study of the influence on the motor state of the stomach of various factors which control the mechanism of emptying. The rate of emptying increases progressively from early digestion until the process is complete. It depends on progressive relaxation of the pars pylorica of which the sphincter is the most efficient segment. The mechanism for control does not appear to be a specific stimulus to relaxation of the segment by free HCl or the products of digestion. Rather the activity of the antrum seems to depend on its irritability, and, in these studies, on the stimulating action of raw protein to vigorous tonic and persistent contraction. With the gradual disintegration of the protein to the products of digestion late in the 1st phase of the digestive cycle, there is apparently a graded reduction on the intensity of the stimulus to the antrum and consequently a progressive relaxation of the antrum with more rapid emptying. The parallel change of the meal to a fluid state probably facilitates the emptying of the stomach.

9786. **McCAUGHAN, JOHN M. Experimental studies on the external secretion of the pancreas with special reference to the effect of its complete loss by permanent pancreatic fistula. I. The coincident changes in the chemistry of the blood. II. The mechanism of death.** *Amer. Jour. Physiol.* 97(3): 459-466. 1931.—Total drainage of pancreatic juice by fistula was fatal to a dog in 8 days, producing characteristic metabolic alterations, particularly anhydremia with moderate elevations of urea preceding death. Subtotal pancreatic drainage was without lethal effect on 2 dogs in 14 and 32 days. In a dog with total pancreatic drainage, daily intravenous injection of

physiologic NaCl solution prolonged life until the 34th day after operation (juice injected the 14th day), the blood chemistry being unaffected. Of 2 other dogs with pancreatic fistulae, 1 which received dialyzable (crystalloid) fraction of pancreatic juice orally died on the 5th day after operation; the other received non-dialyzable (colloid) fraction of pancreatic juice and died on the 12th day. Of 2 dogs with total pancreatic drainage, 1 was early given non-dialyzable fraction of pancreatic juice by mouth; on the 9th day, practically moribund, it was given 200 cc. whole juice intravenously and died. The other dog was given whole juice intravenously beginning with the 5th day, rapidly grew worse, but made a spectacular recovery within a few hrs. on receiving whole juice by mouth, and later died when non-dialyzable portion was substituted for whole juice. The essential cause of early death following total drainage of pancreatic juice is not entirely clear. In general, the loss of salts, water and proteins by way of the pancreatic juice and gastric vomitus must play an important rôle. However, the comparatively slight disturbances in blood chemistry and the improvement in the condition of a moribund dog after oral administration of whole pancreatic juice leave much to be explained.

9787. MACCIOTTA, G. Les activités enzymatiques du pancréas chez le nourrisson. *Rev. Franç. Péd.* 6(1): 72-94. 1930.—The trypsin, amylase and lipase of the pancreatic juice, and the amylolytic, lipasic and antitryptic power of the blood serum were determined in 36 infants, 1 day to 2 yrs. old. The pancreatic juice was found abundant at birth. During the 1st wk. of life the quantity secreted in ½ hr. was about 6-10 cc.; in the 1st month, 8-15 cc.; later 15-30 cc., with proportionally greater values in infants fed on cow's milk. Lipase and trypsin were present in traces in the gastric juice of the new-born; amylase in somewhat higher amount. Trypsin increased during the 1st mo. to about 2-2.5 tryptic units, 3-5 by the end of the 6th mo., 8-12 by the end of the yr. Lipase (measured by cc. of n/10 NaOH) reached a value of 0.15-0.17 in the 2nd wk., 0.2-0.3 the 1st mo., and about 0.5-0.7 after the 2nd mo. Amylase reached 6-8 diastatic units by the end of the 1st wk., 15-20 in the 1st mo., 25-35 in the 3rd, 30-50 up to the end of the 8th, 70-80 later, and still more after the 1st feeding of starchy foods. There appeared to be no necessary or normal mutual relation between the development of the production of the various ferments, but a close relation between each of the ferments and feeding. The lipasic power of the blood serum increased from 0.06-0.1 ccm. soda solution in the first days of life to 0.25-0.35 in the 1st months and 0.35-0.5 toward the end of the yr. The amylolytic power of the serum increased from 0.6 in the new-born to 1-3, rarely 4, during the 1st yr., with an especially accented increase after the 1st month. Both amylolytic and lipasic powers undergo marked individual variations. No close relation, such as could be used for diagnostic purposes, appeared between the diastatic and lipasic powers of the blood and that of the pancreatic juice in the infant.

9788. McDONALD, FRANCIS G., and WALTER C. RUSSELL. The effect of calcium citrate and carbonate upon the evacuation of a protein from the stomach of the albino rat and the pH of the contents. *Amer. Jour. Physiol.* 97(2): 386-391. 1931.—The extent of the evacuation of coagulated egg white from the stomach was significantly greater in the absence of the Ca compounds. Both compounds reduced the amt. of the evacuation when fed either at a high or low level. When the coagulated egg white was fed without the addition of a Ca compound the pH of the contents was 5.3. Upon incorporating 10% and 1.92% Ca citrate in the food the higher level lowered the pH to 4.4, whereas the lower level had no effect. Ca carbonate introduced into the test meal instead of the citrate, in quantities equivalent in Ca content to that of the citrate, increased the pH of the contents to 7.0 in the case of the higher level, whereas the smaller dosage of Ca carbonate raised the value only 0.6 pH over that of the control. The evacuation of the material from the stomach took place to approximately the same extent when a pH of 7.0 was obtained as when a value of 4.4 was observed.—*Authors' summary.*

9789. MAC KAY, MARGARET E. Motor reactions of the small intestine to histamine. *Trans. Roy. Soc. Canada, Sect. 5, Biol. Sci.* 24(1): 197-198. 1930.—To study, in the whole animal, the influence of histamine on intestinal motility, dogs and cats, in which a segment of the gut from the duodenum, jejunum, and ileum had been exposed, were given intravenous injections of histamine. In the 3 exposed loops, there was first a strong initial contraction, due to shortening of the longitudinal layer; it was greatest in the ileum, least in the duodenum. Then there was a period of inhibition in all 3 segments; finally, return to normal. Subcutaneous and intra-intestinal injections of histamine were ineffective. After paralysis of the parasympathetic system by atropine, these effects of histamine are diminished but not abolished.

9790. MACLEOD, J. J. R., H. E. MAGEE, and C. B. PURVES. Selective absorption of carbohydrates. *Jour. Physiol.* 70(4): 404-416. 1930.—The existence of some degree of selective diffusion of sugars through the isolated surviving intestine of rabbits, rats and cats is confirmed. This property is manifested when equal volumes of the sugar solutions are placed in separate segments of intestine, each immersed in its own bath of Tyrode solution at body temp. This selective diffusion cannot be demonstrated when, under the above conditions, mixtures of sugars are used in place of separate solutions of each sugar. Selective absorption is manifested when mixtures of sugars are fed to living rats. That selective diffusion of glucose through the excised intestine occurs most rapidly when the concentration of glucose is about 3M/4 is confirmed. When sugar solutions in concentrations above 3M/4 are fed to rats they are rapidly diluted to about this level by secretion from the gastric glands before being discharged into the intestine. If for any reason they reach the intestine in higher concentrations, congestion of the duodenal mucosa may be produced. The rate of discharge of sugar solutions through the pylorus varies inversely as their concentrations. The concentration of sugar in the intestinal contents depends on the concentration of the sugar solution fed and on the rate of absorption of the sugar. There is some evidence that both of these factors may govern the motility of the pyloric sphincter. Sugars are absorbed in the intestine and not, to any appreciable extent, in the stomach.—*Authors' summary.*

9791. McNEALY, R. W., and J. DANIEL WILLEMS. The absorption of dextrose from the colon. II. A study of the effects of chemical excitants and of stimulants on dextrose enema. *Arch. Surg.* 22(4): 649-657. 1931.—It had previously been shown that a 5% solution of dextrose is not appreciably absorbed from the colon, but that tap water and physiologic NaCl solution are rapidly and efficiently absorbed by the colon. In 6 dogs, a small amt. of dextrose was absorbed by the colon from a mixture of equal parts 5% dextrose and 0.9% NaCl solutions, the NaCl influencing the absorption of the dextrose. In 3 dogs no appreciable amt. of dextrose was absorbed by the colon from a similar mixture of 5% dextrose and 1.5% $NaHCO_3$. In 4 dogs, practically no dextrose was absorbed by the colon from an equal part mixture of 5% dextrose and 6% ethyl alcohol; the alcohol was absorbed, producing hyperglycemia. The authors decide that there is no evidence of any nutritive value in the dextrose enema.

9792. McROBERT, G. R. Observations on the hydrogen-ion concentration of the alimentary canal of the albino rat. *Indian Jour. Med. Res.* 16(2): 545-552. 2 fig. 1928.—The measurements were made with the quinhydrone electrode. In normal rats the pH increases below the duodenum to a maximum of about 8 at the lower end of the ileum. In the cecum the pH is lower

by 2 or 3 units. Starvation or lack of Vitamin D increases the region of high pH.—*R. S. Anderson.*

9793. **MAYO, CHARLES 2nd, and CARL H. GREENE. Studies in the metabolism of the bile. IV. The rôle of the lymphatics in the early stages of the development of obstructive jaundice.** *Amer. Jour. Physiol.* 89(2): 280-288. 1929.—In 3 series of 5 dogs each biliary obstruction was produced by ligation of the cystic and common bile ducts, 1 series being kept as a control for the effect of the obstruction alone, a thoracic duct fistula being established and the lymph drained externally in a 2nd series, and in a 3rd series the thoracic duct being ligated at its point of entrance into the jugular vein. The experiments showed that bilirubin and bile acids rapidly accumulate in the blood after the experimental ligation of the cystic and common bile ducts. The lymph shows an even more rapid accumulation of these 2 biliary products and the external drainage of the lymph through a fistula of the thoracic duct delays the changes in the blood stream, but does not prevent the development of icterus. Ligation of the thoracic duct may delay the entrance of bile into the blood stream slightly but not to so great an extent as does a lymphatic fistula. The results indicate that bile resorption in obstructive jaundice may occur through both vascular and lymphatic channels, although the latter possibly are the more active during the 1st few hrs. of obstruction.

9794. **METTIER, STACY R. The reaction of human duodenal contents to acid and alkaline meat mixtures.** *Jour. Clin. Investigation* 8(4): 561-567. 4 fig. 1930.—Predigested beefsteak (200 gm.) adjusted to pH 3 or 3.2 was fed to 3 patients with achylia gastrica and to 2 patients with a normal gastric secretion. On a subsequent day a similar amount of beefsteak was adjusted to pH 8 and fed to the same individuals. Simultaneous fractional duodenal and gastric analyses showed that the acid meal was an effective means of rendering the gastroduodenal contents acid, over a range of pH 4 or under, and the alkaline meal rendered the contents alkaline, pH 7.8 to 8. The alkaline pH was maintained almost constant for 2 hrs. in the stomach and duodenum of patients with free HCl in their gastric secretion and for 2-3 hrs. in patients with achylia gastrica. The acid pH was maintained almost constant for 1½-2 hrs. in patients with a normal gastric secretion, and 3-4 hrs. in patients with achylia gastrica. The predigested beefsteak meal may be used experimentally in the study of the relation of pH of the upper intestinal tract to inorganic metabolism.—*Author's summary.*

9795. **MIRVISH, L., G. SACKS, and T. SCHRIRE. The absorption of calcium from the gall-bladder.** *Jour. Physiol.* 70(4): 434-440. 1930.—Dogs were used for most of the experiments, but some experiments were also made on cats and rabbits. The volume of bile found in the gall-bladders of 37 dogs ranged from 3 to 21 cc. (av. 11.3 cc.); the gall-bladder was never found empty but was absent in 1 instance. The Ca content of the cystic bile were 29.5-68 mgm. % (107 mgm. in 1 instance; av. 40.5 mgm. % in ♂♂ and 49.2 mgm. % in ♀♀). In 3 dogs the gall-bladder was emptied and washed out; then Ca was administered, duodenally or intravenously. After a certain interval the gall-bladder contents were again removed and the Ca content estimated. It was found that no Ca passes into the gall-bladder from the blood stream, either normally when the gall-bladder is allowed to remain empty, or when it is filled with saline, or when Ca is administered to the animal intravenously or duodenally. In 24 dogs the gall-bladder was emptied, washed and refilled, 9 with $CaCl_2$ solution, 2 with bile plus $CaCl_2$, 7 with cystic bile, 2 with cystic bile in saline solution and 4 with hepatic bile. In nearly all cases the Ca content of the gall-bladder fluid was found definitely lowered 1-2 hrs. later. This demonstration that Ca can be absorbed from bile (probably along with other biliary constituents) seems to indicate the presence of a "Ca circle" in the liver. The Ca taken by mouth is absorbed from the small intestine, taken by the portal vein to the liver, from which a portion passes into the general circulation (via the hepatic veins), and a portion is excreted into the bile. The Ca from the bile is again absorbed in the gall-bladder either by the lymphatics into the portal circulation, or again from the duodenum into the portal circulation. In either case the increased accumulation of Ca in the liver that thus occurs is capable of raising the blood Ca of the general circulation. In the maintenance of the extremely constant concentration of Ca in the blood the endocrine glands, especially the parathyroids, play the largest part; they regulate the storage of excess Ca in the bones, and its liberation from these stores into the tissues when the Ca intake is insufficient. But a simpler and more rapid mechanism seems also to be present, and that is the steady and long-continued supply of Ca to the general circulation from the liver, which is maintained long after the absorption of the meal (containing Ca) is complete.

9796. **NEALE, A. V., and T. G. KLUMPP. The action of histamine on the pancreas.** *Jour. Clin. Investigation* 9(2): 197-208. 1930.—In a study of the action of histamine on pancreatic secretions into the duodenum in about 30 cases, chiefly children of different ages, histamine caused no increase in either the volume or the enzyme activity of pancreatic secretion. An increase in the alkalinity of the duodenal contents (alkaline tide) accompanied the secretion of acid into the stomach in response to histamine.

9797. **PAFFRATH, HANS, und ALFONS KAEHS. Untersuchungen über die Kohlehydratverdauung des Säuglings. VIII. Beiträge zur Verdauungsphysiologie der Malzextrakte.** *Zeitschr. Kinderheilk.* 50(5): 553-563. 1931.—The chemical composition of malt extract was determined for fresh and old extract; no marked difference was found. Absorption experiments, using the small intestine of a rabbit and a Thiry-Vella fistula in a dog, were carried out to compare the rate of absorption of malt extract with that of a dextrin-maltose mixture. For short periods of time the rate is the same, both being absorbed very quickly. In 2-hr. experiments 10-20% of malt extract was not yet absorbed while only a small percentage of dextrin-maltose mixture remained unabsorbed. With malt extract the brown colored colloidal condensation products are practically not absorbed at all. Malt extract was absorbed 3 times as fast as lactose. Caramelized cane sugar is absorbed more slowly than malt extract. It also stimulates secretion. The substances responsible for these effects were shown not to be either the colored or the colloidal substances present. The chemical constitution of the substances responsible is not determined but is probably the same as those of malt extract. To the unabsorbed carbohydrates of malt extract belongs pentosan which constitutes 1.72% of the extract as well as other non-colored and non-colloidal substances of unknown chemical composition. The laxative actions of malt extract are due to the fact that small amounts reach the large intestine and here encourage fermentation whereas the laxative effect of lactose is due to fermentation in the small intestine. It depends upon the ability of the small intestine to absorb lactose and occurs when lactose is present in very large amounts.—*A. C. Ivy.*

9798. **POLLAND, W. SCOTT, and ARTHUR L. BLOOMFIELD. The diagnostic value of determinations of pepsin in gastric juice.** *Jour. Clin. Investigation* 9(1): 107-113. 1930.—The concentration and total output of pepsin were studied in 40 determinations on 36 patients, 21 essentially normal, 5 with duodenal ulcer, 1 with gastric ulcer, 5 with gastric cancer, 2 with pernicious anemia, 1 with sprue and 2 with unexplained anacidity. In normals the maximum 10-min. volume of stomach juice digested from 16,900 mgm. to 112,400 mgm. of edestin. The ulcer cases fell within the same general range. In pernicious anemia, cancer of the stomach, and severe gastritis, the pepsin output was diminished, in some cases to extremely small amounts, but in only 1 case was pepsin completely undemonstrable. No correlation was found between pepsin output and acidity

and it is suggested that the secretory mechanisms of the 2 are independent. Finally, it seems that very low pepsin output is a more delicate index of gastric damage than low acid values.

9799. **QUIGLEY, J. P., [et al.].** The action of insulin on the motility of the gastro-intestinal tract. II. R. D. TEMPLETON and J. P. QUIGLEY. Action on the Heidenhain pouch. III. J. P. QUIGLEY and R. D. TEMPLETON. a. Action on the pyloric pouch. b. Action on the stomach following double splanchnicotomy. IV. [Same authors.] Action on the stomach following double vagotomy. V. J. P. QUIGLEY and E. I. SOLOMON. a. Action on the human duodenum. b. Action on the colon of dogs. *Amer. Jour. Physiol.* 91(2): 467-474; 475-481; 482-487; 488-494. 1930.—II. In dogs fasting 14-40 hrs. intravenous or subcutaneous injections of 8-80 units of insulin inhibit the motility and depress the tone of the Heidenhain pouch at the same time that the tone and motility of the main stomach is being augmented. Intravenous injections of 2-50 gm. dextrose (50% solution) are usually without effect on the motility of the pouch. Feeding dextrose to the animal inhibits the pouch motility.—III. The motility of a pouch made from the pyloric portion of the stomach was not appreciably altered by injections of 16-80 units of insulin or the intravenous injection of dextrose up to 30 gm. The action of insulin and of dextrose on the gastric motility in double splanchnicotomized dogs while fasting is similar to but slightly greater than that displayed by normal animals.—IV. In dogs having the vagi sectioned insulin inhibits gastric hunger contractions while intravenous injections of dextrose are practically without effect on the motility of such a stomach. The mechanism by which insulin and glucose modify gastric motility is considered.—V. Duodenal activity has been followed in man by the double balloon method and has been related to gastric activity. Subcutaneous injection of 12-20 units of insulin was followed by an increase in duodenal activity similar to that which occurred in the stomach. Duodenal hunger contractions can occur in the absence of gastric motility and this duodenal activity can give rise to hunger sensations. Since the duodenal response to insulin preceded that of the stomach it may have given rise to sensations which enabled a subject to predict that a gastric response was about to occur. The response of the duodenum as well as of the stomach has been inhibited by the subcutaneous injection of atropine or the oral administration of cane sugar which is allowed to enter the intestine. Insulin injections produced in dogs an increase in colonic activity which closely paralleled that exhibited by the stomach.—*Authors' summaries.*

9800. **RASENKOW, J. P., und A. N. PTSCHELINA.** Über die humorale Natur der Nervenerregbarkeit. I. *Pflüger's Arch. Ges. Physiol.* 226(6): 786-793. 1931.—Experiments are reported in which blood secured from the veins of the stomach or pancreas, during or after vagus stimulation produced augmented flow of gastric or pancreatic juice when transferred to a second dog. The experiments were done under ether-chloroform anesthesia. If the authors took care to perform the necessary and obvious controls, they have neglected to mention them in this report.—*M. H. Friedman.*

9801. **RAVDIN, I. S., and J. L. MORRISON.** Gall-bladder function. I. The contractile function of the gall-bladder. *Arch. Surg.* 22(5): 810-828. 4 fig. 1931.—Rhythmic tonic contractions are believed to have been observed fluoroscopically in a human gallbladder, respiration having been temporarily checked. The isolated gall-bladders of a dog, a guinea pig and a rhesus monkey responded by rhythmic contractions to stimulation by various drugs. The authors failed to find bile pigment in the lymphatics or blood vessels draining the gall-bladder. Hence they conclude that although certain constituents of the bile are removed by the lymphatics or blood vessels, concentrated bile leaves the gallbladder, as a result of its contraction, by the cystic duct.

9802. **REWBRIDGE, ALLAN G., MILTON T. HANKE, and BÉLA HALPERT.** Further observations on the function of the gall bladder. Experiments with methylene blue on the dog. *Amer. Jour. Physiol.* 95(3): 511-518. 1930.—Four series of experiments were performed: (1) acute experiments with injection, 4 dogs; (2) feeding experiments on 18 dogs; (3) injection experiments on 42 dogs; (4) injection experiments with ligation of a hepatic duct. Methylene blue given intravenously (in doses of 20 mgm., i.e., 2 cc. of a 1% solution per kgm. body weight) to dogs anesthetized with ether, appears in the bile within 30 min., and attains its highest concentration of 1:220 to 1:1,200 within 1-2 hrs. The dye also appears in the saliva, and the gastric and duodenal secretions. In intact dogs, methylene blue ceases to be present in the bile of the liver about the 36th hr. following its intravenous administration; from the content of the gall bladder it usually vanishes 6-24 hrs. after the liver has ceased to produce bile containing the dye. After oral administration, methylene blue disappears from the bile of the liver at about the 30th hr., and from the gall bladder some time between the 30th and 48th hr. after ingestion. Exchange of the content of the gall bladder occurs within about 24 hrs.; this process is retarded when feeding is unsatisfactory.

9803. **REWBRIDGE, ALLAN G., and BÉLA HALPERT.** Roentgen-physiological studies on the gall-bladder: experiments with lipiodol and brominol-light on the dog. *Amer. Jour. Roentgenol.* 24(6): 634-639. 1930.—Normal healthy dogs (26) were laparotomized: 2 cc. of lipiodol was introduced into the gall-bladders of 20, and brominol-light into 6 of the dogs, after 3 cc. of bile had been withdrawn. Following the operation the animals were offered their usual diet. Roentgenograms were taken 6 hrs. after the operation and subsequently once daily until the shadow had vanished or remained stationary for several days. In the latter case, a meal (raw chopped meat and 2 eggs) was fed, and a roentgenogram taken 3 hrs. later and 1 the following day. In the experiments with lipiodol, the shadows on the 1st films averaged about 3.5 by 1.5 cm. The shadow disappeared completely in 3 dogs by the end of the 2nd day, in 5 dogs on the 3rd and 4th days, in 6 between the 5th and 10th days, and in 1 on the 17th day. In the remaining 5 dogs the shadow diminished to about 30% its original size and remained nearly unaltered until the experiment was concluded (8-26 days after operation). In the experiments with brominol-light, the shadows on the 1st films averaged about 2.8 by 2.1 cm. The shadow disappeared completely by the 4th day in 4 of the 6 dogs. At necropsy, droplets of lipiodol or brominol-light were found in the content of the gall-bladder in most of those dogs in which the shadow had disappeared. The exit of lipiodol and brominol-light occurred spontaneously whenever the orifice of the cystic duct became the lowermost point of the viscus. In dogs in which this did not happen the lipiodol remained in the gall-bladder almost indefinitely. The above observations justify the conclusion that complete emptying of the dog's gall-bladder does not occur with each meal; it seems probable that complete evacuation never takes place in the dog.—*Authors' summary & conclusions.*

9804. **ROZEN, JOSEF SAMUEL, and GEORGE LOUIS PERUSSÉ, Jr.** The effect of calcium and magnesium ions on the gastric hunger contractions. *Amer. Jour. Physiol.* 91(1): 298-304. 1 fig. 1929.—From experiments on 5 dogs it is concluded: (1) Mg salts given orally cause an inhibition of hunger contractions that can be counteracted by giving Ca salts. Ca administration per se has no effect on hunger contractions. (2) Central effects caused by injections of Mg and Ca salts may mask any true effect of these salts on hunger contractions. Cessation of hunger contractions and loss of tone were the effects observed. Very small doses of Ca have no effect on hunger contractions. A Ca injection following Mg injection does not diminish the depressive action of the Mg on the hunger contractions. (4) Mg depresses rhythmical contraction of gastric muscle

strips. Ca enhances gastric strip contraction. Ca after Mg depression allows contraction to return to normal more quickly than does bathing with the original Locke's solution. In bathing with Ca and Mg solutions simultaneously, the Ca effects predominate.—*Authors' conclusions.*

9805. **ROUX, JEAN-CHARLES. L'équilibre entre les fermentations et les putréfactions dans le côlon. Ses variations et leur valeur séméiologique.** *Arch. Malad. Appar. Digest. et Malad. Nutrit.* 20(4): 401-442. 1930.—During several thousand fecal examinations Roux has found that in normal feces there is a fairly stable equilibrium between acids and ammonia, the acidity fluctuating around 15 cc. per 100 gm. feces and the ammonia between 2 and 4 cc. The ammonia is volatile and readily absorbed by the intestinal mucosa; the amount in the feces at the time of their discharge is therefore in proportion to the length of their sojourn in the intestine. The amount of acids normally present is regulated (particularly in the colon) by various factors, including bacterial proteolysis, secretion of alkaline bases by the mucosa of the large intestine, and absorption of the acids and their soluble salts during their passage through the colon. A disturbance of this acid-ammonia equilibrium is in general indicative of disease. A decrease in organic acidity (with or without increase in ammonia) generally accompanies high intestinal putrefaction. An increase in organic acids (with or without decrease in ammonia) may produce a diarrhea, which is an attempt of the organism to protect itself against a disturbed equilibrium. Hyperacidity of the feces may also stimulate the formation in the colon of soaps from the bases secreted by the intestinal wall. Increase of ammonia is the exception rather than the rule in feces deficient in acids. High acidity is freqently accompanied by decrease in ammonia and in putrefactive processes, but may coexist with high ammonia, e.g., (1) when excess of acid production in the cecum and ascending colon irritates the descending colon into production of an albuminous secretion causing secondary putrefactions; or (2) when in certain enteritides, from imperfectly understood causes bacterial decomposition is not maintained at its normal level, and excessive putrefaction and fermentation exist side by side. In certain persons the intestinal flora never becomes stabilized, and acid diarrhea alternates with putrid diarrhea.

9806. **RUDD, G. V. Observations on the acidity and chloride content of the gastric juice.** *British Jour. Exp. Path.* 11: 240-244. 1930.—A comparison was made of the gastric secretory response to a meal of gruel and to one of cream. A fractional analysis of the gastric contents was done and total and neutral chloride and total acidity estimated in the samples. The total chloride content of the gastric secretion remains approximately constant whilst the total acidity and neutral chloride show wide variations. The theory of the formation of neutral chloride by the neutralization of gastric acid by duodenal fluid is incapable of explaining these results. The variations in the composition of the gastric contents are due to changes in the amounts of HCl and neutral chloride being secreted by the gastric mucosa. In an estimation of the secretory activity of a stomach the total chloride is the significant quantity.—*J. Bland.*

9807. **SCHWEZOFF, S. W. Experimentelle Studien zur Frage der Leberfunktionsprüfung.** *Zeitschr. Ges. Exp. Med.* 73(3/4): 285-292. 1 fig. 1930.—Phenoltetrachlorphthalein intravenously injected into the peripheral blood stream (11 tests on 11 animals, cats and a dog) was always found in the internal veins (hepatic and portal) in 10-15 min., but with some quantitative irregularities: in 22% of the cases more tetrachlorphthalein was found in the portal vein, in 78% in the hepatic vein. Bilirubin, intravenously injected into the peripheral blood-stream (21 experiments on 21 cats) was likewise always found in the hepatic and portal veins in 10-15 min., but with quantitative regularity, less bilirubin being found in the hepatic and more in the portal vein. Schwezoff concludes that the bilirubin test is physiologically better founded than the phenoltetrachlorphthalein test.

9808. **SMIRNOV, N., A. BOGDASSAROV, et Z. TCHOUKANOVA. De la sécrétion gastrique a jeun.** *Arch. Malad. Appar. Digest. et Malad. Nutrit.* 20(3): 296-309. 1930.—More than 450 aspirations were made on 143 fasting patients including chiefly sufferers from gastric affections and also some with no disease of the stomach. The quantities withdrawn varied from 2 to 60 ccm. (av. 35 ccm.). The total acidity of the first fluid obtained was 5-60 (av. 30); free acid, 20. In some cases, but not consistently in all, there was a relation between the quantity and the acidity of the first sample. The acidity of the later secretion was generally greater than that of the earlier; it was 30-80 (av. 60); free HCl 50. The quantity of later secretion for a unit of time was not constant during a single aspiration; the quantity obtained during ½ hr. varied generally from 15 to 45 ccm. The fasting acidity was in 70.7% of the cases lower than after a test meal, showing that the fasting test cannot replace the test meal. The best results were obtained by aspiration immediately after awaking, eliminating psychic complications.

9809. **SMITH, GEOFFREY H. Factors affecting the deposition of dental calculus.** *Australian Jour. Exp. Biol. and Med. Sci.* 7(1/2): 45-77. 1 pl. 1930.—Experiment indicates that loss of CO_2 from saliva is of slight importance as a cause of dental calculus deposit. The pH of saliva is not influenced by different types of diet, nor does it correspond with changes of urinary pH, which can be readily produced by such alteration of the diet. The pH curve for saliva takes approximately the same course each day, irrespective of the diet and the urinary pH. Probably the pH of saliva does not show large enough variations from the normal to exert any marked influence on calculus. A method for the estimation of phosphoric acid in saliva is described, and values of organic and inorganic phosphates are given. There is no observable relation between the amount of organic phosphates present in saliva and a tendency to calculus deposit. The presence of a phosphatase in saliva has been confirmed; it is contained in the desquamated epithelial cells, which are normal constituents of the saliva, and increases the free phosphate by its action on the organic phosphate compounds in the saliva. It exerts a similar hydrolytic action on sodium glycerophosphate. The optimum reaction for the salivary phosphatase is about pH 5.5. The organic phosphate in the saliva is probably of the nature of a phosphoric acid ester. The phosphatase content in different persons depends largely upon the conditions of the gums and oral mucous membrane. The use of the toothbrush diminishes the amount of phosphatase in saliva, and shows the importance of brushing the gums as a prophylactic measure against calculus formation. A deposition of Ca phosphate in the epithelium of the gums has been produced in vitro. Attempts to show that such a deposit occurs in epithelium taken directly from the mouth have not been successful.—*Author's conclusions.*

9810. **TSCHUKITSCHEFF, J. P. Über den Mechanismus der Hungerbewegungen des Magens. I. Einfluss des "satten"- und "Hunger"-Blutes auf die periodische Tätigkeit des Magens.** *Pflüger's Arch. Ges. Physiol.* 223 (3): 251-265. 5 fig. 1929.—On dogs each with a gastric (fundal) fistula, 41 transfusions were performed with blood from fasting and recently fed dogs. "Satiated" blood (from recently fed dogs) inhibited the periodic motor activity of the stomach, the greatest effect being produced by blood from a dog fed with meat, which produced a lowering of tonus of gastric contractions in 2-4 min. after the beginning of the transfusion, and a complete cessation of contractions in 5 min. (the gastric juice becoming acid soon after the beginning of transfusion). Hunger blood produced one or the other of 2 opposed effects: in most cases in increased gastric activity (the gastric juice being alkaline before and after the transfusion), but in some cases an inhibition like that produced by "satiated" blood. The difference be-

tween the results from "satiated" blood and hunger blood points to differences in physicochemical composition. The more difficult question of the same results obtained with blood from fasting and recently fed dogs was studied by transfusion with blood taken during different periods of the hunger contractions; the author believes that results show that blood taken at moments of periodic contraction must be regarded as in effect hunger blood.

9811. VILLARET, M., L. JUSTIN-BESANCON et A. MARCOTTE. Technique d'enregistrement des mouvements rythmiques de la vesicule biliaire. *Compt. Rend. Soc. Biol.* 106(9): 720-722. 1931.—Apparatus and method are described which simplify the method of Ischiyama. Normal, spontaneous contractions were of 3 kinds: feeble, medium, and strong. In the 2 min. interval between strong contractions come small, rapid, secondary ones. The duration and amplitude of the strong contractions are very variable. Strong contraction resulted with the smallest doses of pilocarpine and various mineral waters, and relaxation with atropine.

9812. VINEBERG, ARTHUR M. The activation of the different elements of gastric secretion by variations of vagal stimulation. *Trans. Roy. Soc. Canada, Sect. 5, Biol. Sci.* 24(1): 189-191. 1930.—By applying weak and strong rhythmic stimulation to the vagi in the neck, different types of secretion could be obtained from the gastric glands of the dog. Hence it may be supposed that the vagi have different secretory fibers which have relation to the different secretory elements of the peptic glands.—*Author's conclusions.*

9813. WEBSTER, D. R. The mucus of the gastric juice and its variations. *Trans. Roy. Soc. Canada, Sect. 5, Biol. Sci.* 24(1): 199-200. 1930.—A note.

9814. WELKER, D. H., and O. BERGEIM. Protein digestion in the human stomach. *Proc. Soc. Exp. Biol. & Med.* 28(4): 383-384. 1931.—The ratio of soluble to insoluble protein in gastric contents of 24 normal men was followed by analysis of material aspirated from the stomach at 15 min. intervals after the meal. The test meal consisted of 80 gm. of bread made from flour containing 0.25% red iron oxide; it is assumed that the oxide adhered to the undissolved portion, and that the ratio of undissolved protein: iron is an index of the amount of protein digestion. The method gave good results.

9815. WESTPHAL, K., F. GLEICHMANN, und Gg. SOIKA. Tierexperimentelle Beobachtungen über nervös bedingte Resorptionsschwankungen der Gallenblase mit teilweiser Berücksichtigung des Lebergallenflusses. *Pflüger's Arch. Ges. Physiol.* 227(1): 204-219. 1 fig. 1931.—The concentrations of various constituents of the gall-bladder contents was studied after ligation of the cystic duct without impairment of the vascular and nerve supply; concentration of all constituents except chlorid was observed. Following peripheral stimulation of the severed cervical vagus changes in concentration of bilirubin, solids and ash of similar order of magnitude and in same direction occurred, but the chlorid concentration decreased in only 2 of 4 experiments reported, and the cholesterol concentration showed no marked increase. Acidity increased from about pH 6.5 to pH 6.0 in 150′ interval. Employing injection of suprarenin (5 mgm. in 100-150 c. c. physiological NaCl solution) as a means of stimulating the sympathetics, the increase in bilirubin content is much reduced, as is that of the solids. Changes in chlorid, cholesterol and ash concentration are variable and of small order of magnitude. Continued injection of suprarenin over a 5 hr. period gave more marked results. The authors conclude that vagal stimulation increases the concentration, while the sympathetic effect is an inhibition of concentration. They claim that increased motility parallels increased concentration. Decrease of motility is frequently correlated with arrest of reabsorption, it is not always absolute as shown by the use of atropine. Bile from hepatic ducts is practically isotonic with bile of gall bladder and with blood. On vagal stimulation, this bile flowing from the liver exhibited inverted changes in most constituents (chlorid, noteworthy exception) when compared with simultaneous observations of biliary concentration in gall bladder; it became also more alkaline. Vagal stimulation expedited the secretory process in a control dog but inhibition resulted in an animal without water. The authors conclude that fluctuations in reabsorption in the gall-bladder may be nervous in origin, and in addition to the physical-chemical processes they assume a vital one also.—*B. McGlone.*

9817. ABDERHALDEN, EMIL, und SEVERIAN BUADZE. Über das Auftreten der Abderhaldenschen Reaktion nach parenteraler Zufuhr des Hypophysenpräparates Prähormon und des Ovarialhormons Follikulin (Menformon). *Fermentforsch.* 12(2): 262-272. 1930.—After subcutaneous injection of "Menformon" or prehormone into normal and castrate male and female dogs, the urine sediment can be shown to contain antiferments for ovarian, hypophyseal, and testicular substances. Such evidence of the Abderhalden Reaction in response to injection of the substance of internal secretions has not before been recognized. Its bearing upon cases under hormone treatment or upon cases of hypersecretion should be studied. It is conceivable that test of the output of hormone by the ovary and especially by the corpus luteum would show relation with the menstrual cycle.—*E. McCoy.*

9818. ABDERHALDEN, EMIL, und ERNST WERTHEIMER. Über das Auftreten von Proteasen im Blut bzw. Harn nach parenteraler Zufuhr von Thyroxin, Adrenalin und Insulin. *Fermentforsch.* 12(3): 421-431. 1931.—Following parenteral introduction of the above mentioned hormones, there appear in the blood and urine of dogs proteases, specific for the organ substrate if the dosage has been small, and non-specific if large. The reaction with adrenalin and thyroxin particularly tends to be non-specific. Specific reaction for the thyroid may appear even in a dog devoid of thyroid gland. The specific proteases continue to appear and are detectable by the Abderhalden reaction for a week after the original introduction of hormone.—*E. McCoy.*

9819. ANSELMINO, KARL JULIUS, und FRIEDRICH HOFFMANN. Nachweis einer acetonkörpervermehrenden Substanz (Schilddrüsenhormon) im Blute von Schwangeren. *Arch. Gynäkol.* 145(1): 95-103. 1931.—Five injections of 2.5 cc. each at 12 hr. intervals of non-pregnant (human) serum were made in 6 ♂ rats; of preg-

nant serum (2nd-10th mo. of normal pregnancy) in 12 rats; of parturient, and 2nd and 6th day puerperal, serum in 2 rats each; of maternal and fetal serum in 2 each; and of pure 10th mo. serum, its ultrafiltrate, and the precipitate from the ultrafiltrate (4 rats); 2 untreated rats served as controls. Graduated doses of thyroxine (5 times 0.025-0.07 mgm.) were given 4 rats for comparison. The rats were killed 12 hrs. after last injection. A substance, identified as thyroid hormone, which increased the rat acetone bodies, was present in pregnant serum only. Appearing in the 1st months, at the end of pregnancy there was enough to double the normal amount of acetone bodies. The hormone decreased rapidly during the puerperium, only traces being present on the 6th day; it was not found in fetal serum. At term 1 cc. serum was equivalent to 10 γ thyroxine. The author believes the substance arises from increased thyroid activity during pregnancy; this leads to increased mobilization and oxidation of carbohydrate, and decreased glycogen in the body and thus, by attacking the fat reserves, to increased acetone bodies.

9820. AOMURA, TETSUTARO. Comparison of the epinephrine content of the suprarenal vein blood of rabbits, dogs, goats and badger determinable by means of the rabbit intestine segment and of the cat paradoxical eye reaction. *Tohoku Jour. Exp. Med.* 14(4): 291-315. 1929.—Determinations of epinephrine in the venous blood collected from the cava of rabbits, dogs, goats and badger and in extracts of the suprarenals of such animals were performed. The standard used was adrenalin chloride. Several colorimetric methods were employed and compared with the rabbit intestine strip and the cat paradoxical eye methods. The latter 2 methods yielded higher figures than the former. A tentative explanation is offered.—*M. Sahyun.*

9821. AOMURA, TETSUTARO. On the epinephrine in the blood of the suprarenal vein and in the suprarenal extract from the rabbit during pregnancy. *Tohoku Jour. Exp. Med.* 14(4): 316-334. 1929.—Determinations of epinephrine in venous blood removed from the cava of pregnant rabbits during various stages of pregnancy were made, also of the extracts of their suprarenals. In the case of venous blood of non-pregnant rabbits, the rabbit intestine strip method and the cat paradoxical eye method showed a ratio of 1:1.5, while a ratio of 2.2:1 was obtained with the venous blood of pregnant rabbits. The author believes that there is a greater secretion of epinephrine during pregnancy in rabbits. —*M. Sahyun.*

9822. BENEDETTO, ELENA di. Acciôn de la floridcina sobre los sapos hipofisoprivos. [Phlorhizin in hypophysectomised toads.] *Rev. Soc. Argentina Biol.* 7(2): 196-202. 1931.—After extirpation of the pituitary, or only of the anterior lobe, phlorhizin usually does not produce glycosuria; it produces hypoglycemia convulsions and high mortality. Lesions of the infundibulum produce a slight decrease in the effects of phlorhizin due to inhibition of the pituitary. Implantation of anterior lobe in operated animals restores the usual effect of phlorhizin, there is glycosuria and the blood sugar values approximate those of normal phlorhizinized animals.—*J. T. Lewis.*

9823. BOSE, J. P. Inter-relationship of some of the important endocrine glands, with special reference to the part they play in influencing the colour and texture of the skin. *Indian Jour. Med. Res.* 18(1): 227-248. 1930. —The action of adrenalin and insulin on the blood-sugar of rabbits, of the white, brown, and colored varieties, was investigated. It was found that, whereas the blood-sugar rise per 0.1 mgm. of adrenalin was 62% in the albino rabbits, it was only 13.8% in the brown variety. Also, whereas insulin caused a fall of 29.7% of blood-sugar per P. R. Unit in the albino, it caused a fall of 36.6% in the brown variety. That the thyroid takes a leading part in influencing the relation between the action of adrenalin and insulin was shown by the fact that the adrenalin response causing a 62% blood-sugar rise in the albino rabbits dropped to 34.2% after thyroidectomy; also that the insulin response causing a blood-sugar fall of 29.7% increased to 47.1% after the operation. In human subjects suffering from diseases influencing the pigmentation of the skin responses to adrenalin and insulin fall into the following groups:—(*a*) Leucoderma, albinism—loss of pigmentation; and (*b*) Chloasma, kala-azar—increased pigmentation. A group of normal healthy Indians were treated as controls. Adrenalin caused a much higher rise in blood-sugar and also of systolic pressure in the leucoderma cases than in group (*b*) or in normal subjects. Insulin caused a greater reduction of blood-sugar in the pigmented cases than in the leucoderma or the normal cases. Cases of leucoderma and albinism behaved like the albino type of rabbits as regards the adrenalin and insulin responses, while cases showing increased pigmentation behaved like the pigmented rabbits. A group of cases of kala-azar of varying degrees of severity which gave a very poor adrenalin response before treatment were next selected, and adrenalin and insulin response were tested again after a course of injection of Sb compounds to see if these responses would be influenced thereby. While adrenalin caused a rise of 14.5% of blood-sugar and 7.2% of systolic pressure before treatment, these values rose to 29.5% and 12.5% respectively after treatment, definitely indicating an improvement in the function of the supra-renal glands. Also, whereas before treatment, insulin caused a greater fall (34.8%) in the blood-sugar, the fall was reduced to 19.5% after treatment, showing that the improved adrenal function caused a greater release of sugar from the glycogen storehouse of the liver, which, to a large extent, neutralized the action of insulin on blood-sugar.—*J. P. Bose.*

9824. BRAIER, BERNARDO. Metabolismo nitrogenado de los perros hipofisoprivos en el ayuno. [Protein metabolism of fasting hypophysectomised dogs.] *Rev. Soc. Argentina Biol.* 7(2): 140-157. 1931.—Hypophysectomised dogs on ample diet have a normal N excretion. Creatinin is somewhat reduced (9-18%). Fasting hypophysectomised dogs eliminate 30-35% less N and creatinin than the controls, their glycemia falls markedly and they often have hypoglycemic convulsions which, if not relieved by glucose injection, may cause death. Dogs with extensive lesion of the tuber behave as normal animals.—*J. T. Lewis.*

9825. CASTILLO, ENRIQUE B. del, y C. J. CALATRONI. Ciclo sexual periódico y foliculina. *Rev. Soc. Argentina Biol.* 6(2): 108-133. 1930.—Daily injections of 0.1-2 units were given to rats during several months. A latent period, summation of effect, after-discharge, and tendency to periodicity more marked with time, were observed. In castrates in spite of continued injections periodic oestrus is observed. Ovary and corpus luteum are not indispensable for periodicity of cycle. Uterus and vagina have a periodic activity, autonomous or governed by an unknown factor, which is manifest in the presence of folliculin.—*J. T. Lewis.*

9833. GUTMAN, MARTIN. Vergleichende Hormonstudie über die Verteilung des Ovarialhormons im Organismus der Säugetiere. *Monatsschr. Geburtshülfe u. Gynäkol.* 79(6): 433-439. 1928.—The content of the oestrus-producing hormone in various tissues was studied by implanting the tissues in female mice. Oestrin can be thus demonstrated in human corpora lutea up to the middle of pregnancy. Human placentae and amniotic fluid are good sources of oestrin. The lower mammals are not comparable to man in this respect. Oestrin was demonstrated in mouse placenta but not in placentae from other species. In all species the hormone is present in follicular fluid and walls. It may be that this method was not sufficiently sensitive to show the presence of small amounts of hormone and that the distribution may not be so widely different. If the results are correct Gutman points out a practical application, that human placenta is a good source of oestrin, but that cow placenta can not be so used. The urine of pregnant women is also a good source of oestrin.—*E. W. McHenry.*

9837. HARTWICH, ADOLF, und GEORG HESSEL. Der Einfluss der Blutdruckzüglerausschaltung auf den Adrenalingehalt des Blutes. *Zeitschr. Ges. Exp. Med.* 76(1/2): 263-289. 1931.—The aortic and sinus nerves in rabbits were eliminated by cutting, tying, clamping, and saturation with 5% phenol. The vasoconstrictor power of blood from the vena cava above the adrenal veins is almost always increased, but that of arterial blood not regularly so. Comparison of the effects of adrenal extirpation and ergotamin and atropin poisoning show that in part of the cases the increase in vasoconstrictor power of the blood is due to epinephrine, and in others to non-specific constriction. Epinephrine probably does not play a rôle in the increased blood pressure after the elimination of the aortic and sinus nerves since it only rarely reaches a magnitude in arterial blood which is sufficient to increase the blood pressure.—*L. K. Alpert.*

9838. HOUSSAY, B. A., L. GIUSTI, y J. M. LASCANO GONZÁLEZ. Implantación de hipófisis e hiperfeminización de los cobayos con injerto ovárico. [Implantation of pituitary and hyperfeminization of guinea pigs with ovarian grafts.] *Rev. Soc. Argentina Biol.* 7(2): 103-114. 1931.—Homologous pituitary implantation in normal and castrated guinea pigs is favorable to the development of a grafted ovary and to its stimulating action on the mammary gland. The ovarian graft (intrarenal) always had a great number of fully developed follicles but no corpora lutea, both in normal and castrate male guinea pigs; in castrates which had received pituitary, hemorrhagic follicles and corpora lutea were sometimes found.—*J. T. Lewis.*

9839. HOUSSAY, B. A., L. GIUSTI, y J. M. LASCANO GONZÁLEZ. La acción del injerto de ovario en machos sobre las vesículas seminales. [Action of ovarian graft in males on the seminal vesicles.] *Rev. Soc. Argentina Biol.* 7(2): 115-124. 1931.—Ovarian grafts in adult male guinea pigs produce considerable hypertrophy of the seminal vesicles. In castrates ovarian grafts do not delay atrophy of vesicles, therefore they act through the testes. Implantation of pituitary also produces enlargement of seminal vesicles in intact animals but not in castrates. Daily injections of folliculin (oestrin) during 35 days produce hypertrophy of the mammary gland but have no effect on the testicles and seminal vesicles. The ovarian graft possibly stimulates the production of pituitary sex hormone which in turn acts on the testicle and by this mechanism the seminal vesicles are hypertrophied.—*J. T. Lewis.*

9840. JORPES, ERIK. On the chemical composition of the islands of Langerhans in the Monkfish (Lophius piscatorius, L.). *Jour. Biol. Chem.* 86(2): 469-476. 1930.—The present study was undertaken with the view of comparing the islet tissue with the normal pancreatic tissue in the selachian fishes. As experimental material the islet tissue of the monkfish (*Lophius piscatorius,* L.) was chosen. The corresponding glands from the summer flounder (*Paralichthys dentatus,* Girard) were also analyzed. The nucleic acid content of the fresh glands and their lipid-free dry substance were analyzed for P and pentoses. In *Lophius,* where the islands form large separate organs, these do not have the typical composition of the pancreatic tissue. The content of nucleic acid is much lower than in the normal pancreas of selachian fishes and of mammals. On the other hand the content of phospholipids is higher.—*I. I. Lemann.*

9841. KALLAS, H. Parabiose, Geschlechtsdrüsen und geschlechtsspezifischer Antagonismus. *Endokrinologie* 6 (3): 188-198. 7 fig. 1930.—Injection of anterior pituitary into one of a pair of parabiotic rats gave rapid increase in the ♀ gonads of recipient, and some development but not nearly so marked in the other. Ovarian tissue was transplanted into a normal male, which latter was placed in parabiosis with a castrated ♂ or in some cases with a ♀. Using mammary glands as a check, decided changes became evident within 3 weeks in the castrated animal. This does not occur in the parabiotic ♂ where recession of gonad and accessory glands occur. However, in simple transplantation of an ovary into a normal ♂, examination of testicle, seminal vesicles and prostate show them to be enlarged rather than reduced. Microscopic examination showed spermatogenesis in full sway. The ovary

transplant, which had been placed in the kidney, showed typical conditions. The author believes there is an antagonism between the ♂ and ♀ sex glands.—*B. Cunningham.*

9842. KLEIN, W., G. PFEIFFER, und G. HERMANN. Der chemische und histologische Nachweis der Jodspeicherung in der Schilddrüse. *Biochem. Zeitschr.* 225 (4/6): 344-351. 4 fig. 1930.—In 2 ♂ dogs, after a preliminary period on I-poor diet, 1 lobe of the thyroid of each was removed and analyzed; then both were given daily doses of organic I (Iodtropon) for 7 days, after which the remaining lobe was removed and analyzed. The I content of the 2nd lobe in each amounted to 5 and 5½ times respectively that of the 1st lobe. In a similarly treated dog fed inorganic I (KI) only a small amount of I was stored. Histologically, however, the thyroid in the 3d dog appeared to be in a condition different from that of the thyroid in the 2 others, being perhaps inhibited in its storage activities by hormones from other endocrine glands.—*R. G. Turner.*

9843. KOJIMA, TAKEO. The effect upon the life of rabbits of the removal of the main suprarenals and the accessory suprarenal cortical tissue. *Tohoku Jour. Exp. Med.* 13(5/6): 357-378. 1929.—Total extirpation of the main suprarenals and the accessory cortical tissue was accomplished by a 4-stage operation which was successful in most cases. 70% of the animals died within 14 days and the longest survival was 35 days. Congestion and hemorrhage of the intestinal tract was the outstanding pathological change in rabbits having total cortical extirpation, severity differing from case to case. These changes were not so marked in doubly suprarenalectomized rabbits presenting accessories at autopsy. The remaining main gland hypertrophies markedly when accessories and one gland are removed. Removal of both main glands and some accessories seems to accelerate hypertrophy of remaining accessories. Accessory cortical tissue was found in 70% of normal rabbits.—*A. G. Eaton.*

9844. KOJIMA, TAKEO. The effect of the removal of the main suprarenals and accessory cortical tissue upon the basal metabolism of rabbit. *Tohoku Jour. Exp. Med.* 13(5/6): 379-404. 1929.—The metabolic rate of rabbits after double suprarenalectomy fell slightly after the operation, due to the operation itself, but soon returned to the preoperative level. In animals which had survived 1-2 yrs. the metabolic rate was not different from the normal. Accessory cortical tissue was found in these animals and was markedly hypertrophied in those surviving for long periods. When the main suprarenals and all accessory cortical tissue was removed the metabolic rate began to fall a few days before death and fell more rapidly during the last few days.—*A. G. Eaton.*

9845. KUGA, S. Studies on Zondek-Ascheim's pregnancy reaction. II. The distributions of the so-called hormone of the frontal lobe of the hypophysis cerebri. [In Japanese, with English summary, p. 57.] *Jour. Oriental Med.* 14(6): 1931.—Hormone of the anterior lobe of the hypophysis was found in the blood of a pregnant woman, the urine of a woman 7-8 days after delivery, the urine of a patient suffering from chorioepithelioma malignum (more than in the urine of pregnancy, and increasing with severity of symptoms), decidua, placenta, hydatidiform mole, urine of a 5-6 day old infant, saliva of a pregnant woman (very little), vaginal secretion of a pregnant woman (very little, but more than in the saliva).

9846. LENDEL, E., und J. N. DUTT. Die Beeinflussung der interferometrischen Abbaukurve der Drüsen mit innerer Sekretion durch erhöhte Temperatur. *Fermentforsch.* 12(3): 333-340. 5 fig. 1931.—In cases of febrile diseases which have certainly no endocrine disturbance, a marked increase in the suprarenal values is noted. This has been previously observed in connection with the fever treatment of exophthalmic goitre following injection of animal blood; it appears to be due to the fever alone. The values for other internal secretions (of the hypophysis, thyroid glands, ovary and testis) are normal or only slightly increased by fever.—*E. McCoy.*

9847. [LINTVAREVA, N. O.] ЛИНТВАРЕВА, Н. О. О влиянии экспериментального гипертиреоидизма на беременность у морских свинок. [Effect of experimental hyperthyroidism on pregnancy in guinea pigs.] [English summary.] Труды Лаборатории Экспериментальной Биологии Московского Зоопарка. (*Trans. Lab. Exp. Biol. Zoopark, Moscow*) 5: 107-119. 1929.—Experiments were conducted on 20 ♂ and 55 ♀ guinea pigs, of which 40 were fed thyroidin and 15 kept as controls. All ♀♀ were separated from the ♂♂ after 4 days. In the 1st series ♀♀ were fed thyroidin immediately upon separation; those receiving doses above 0.025 gm. remained sterile; half of the controls and those fed doses 0.025 gm. became pregnant. In the 2nd series some ♀♀ were fed thyroidin for 1, 2, 3, 5 days; only those fed for 1-2 days became pregnant. In the 3rd series thyroidin was fed on the 3rd, 5th, and 7th day after separation from the ♂♂; pregnancy always appeared independently of the length of feeding and amt. fed. Thyroidin caused premature degeneration of corpora lutea and cystic regeneration of ovaries. The author explains sterility provoked by thyroidin by the impossibility of egg implantation in the uterine wall due to degeneration of corpora lutea. This sterility was temporary, disappearing with the cessation of thyroidin feeding.

9848. MacARTHUR, C. G. A new posterior pituitary preparation. *Science* 73(1895): 448. 1931.—Preparation is described of a product, apparently a polypeptide containing labile S, which acts strongly on blood vessels and isolated uterus but not on frog melanophores.

9849. MAHNERT, A. Weitere Untersuchungen über die Beziehungen zwischen Hypophysenvorderlappen und Ovarium. Zugleich ein Beitrag zur Frage der hormonalen Sterilisierung. *Zentralbl. Gynäkol.* 54(46): 2883-2887. 3 fig. 1930.—In 3-14 days after injection of 2-2½ rabbit units of corpus luteum extract, 12 of 15 rabbits had coitus; 8 were killed 24 hrs. thereafter; in only 1 was there any rupture of the follicles. The other 4 proved not to be pregnant. Two rabbits each received 120 mouse units folliculin or 2 rabbit units prolan; in none was rupture of the follicles prevented. Prevention of rupture shows that the corpus luteum hormone has an action opposite to that of the anterior lobe.

9850. MONAUNI, JOSEF. Untersuchungen am quergestreiften Muskel epinephrektomierter Tiere. I. und II. *Arch. Exp. Path. u. Pharmakol.* 140(5/6): 306-327; 328-339. 1929.—I. The muscle membranes of guinea pigs from which adrenals had been removed showed an increased permeability to water. The number of mgm. of KCl in 1 gm. of muscle in operated animals ranged from 2.89 to 3.6 and in controls from 3.6 to 4.2 when perfused with KCl. The mgm. of Ca per gm. of muscle ranged from 0.63 to 0.80 in operated animals and from .71 to .96 in controls when perfused with $CaCl_2$. These changes apparently were due to the function of the adrenal itself and not merely to injury caused by its removal.—II. In Trendelenburg frog preparations, removal of the adrenals gives rise to edema. This edema is dependent on changes in the blood vessel endothelium and changes in muscle permeability. The osmotic pressure of the muscle cells decreased when the adrenals were removed. The K content decreased and the Ca content of muscle increased.

9851. PENAU, H., L. BLANCHARD, et H. SIMONNET. Le problème des glandes à sécrétion interne. Les propriétés physico-chimiques et pharmaco-dynamiques des hormones. I. L'hypophyse. (Les Problèmes Biologiques. Vol. 12.) 249p. 9 fig. Les Presses Universitaires de France: Paris, 1929. Pr. 45 fr.—A summary of the literature on the physiology of the hypophysis, without original observations. The 2nd part, on the posterior lobe, is the more extensive, and gives a summary of many biological methods used in preparing and testing

posterior lobe extract. No attempt is made to cover pathological or clinical problems.—*T. J. Putnam.*

9852. **SAITO, ISAO. Parathyreoidektomierte Kaninchen und Trächtigkeit.** *Tohoku Jour. Exp. Med.* 15 (3/4): 333-354. 1930.—Two parathyroid glands were removed from each of 5 rabbits, which were later mated. The changes in the N content and distribution of the blood and urine were studied. Tetany did not develop but 3 of the rabbits died during the period of pregnancy and the other 2 aborted. The non-protein N and urea content of the blood increased slightly after the operation and more markedly during the first 10 days of pregnancy. The latter change was accompanied by smaller increases in the amino-acid and uric acid content. Thereafter, all these values returned to the normal. The N distribution in the urine showed no significant change other than a marked decrease in the amount of uric acid after the operation. There were no control experiments, either upon normal pregnant rabbits or upon non-mated parathyroidectomized rabbits. —*I. Greenwald.*

9853. **SCHOELLER, W., M. DOHRN, und W. HOHLWEG. Die perorale Wirkung des Follikelhormons. [Peroral action of follicular hormone.]** *Wien. Arch. Inn. Med.* 21(2): 323-328. 1931.—Using aqueous and oil preparation of follicular hormone, 20,000-8,000,000 mouse units per gm. (in 6 doses of 0.2 cc. each to castrated ♀ rats), the effect was inversely proportional to the purity of the preparation (58 rat units of the pure crystallized hormone and 6 rat units of 1/50 this purity produced estrus in 50%). When substances promoting resorption were added to dragées 3.5 rat units had the same effect as 8.5 rat units otherwise. A dose of 7 rat units divided into 7 aliquots produced estrus in 50% of the rats; given as a single dose, in only 15%.

9854. **STEINACH, E., und H. KUN. Luteingewebe und männliche Geschlechtscharaktere.** *Pflüger's Arch. Ges. Physiol.* 227(3): 266-278. 15 fig. 1931.—X-radiation of ♀ guinea pigs produced complete luteinization of the ovaries accompanied by enlargement of clitoris, urethral elevations into a preputium, and masculine attitude toward other ♀♀. After 50-100 rat units anterior lobe hormone had been injected daily into ♀ guinea pigs for 17-24 days the same occurred; the first changes appeared on the 6th day; ovaries removed a few weeks after injections began were luteinized like those of irradiated animals. Masculine attitude developed. It would appear that the lutein cells contain an incretion corresponding to the ♂ sexual hormone, which will cause the development of ♂ sexual characteristics in ♀♀ if present in sufficient quantity. Castrated females 8 mo. old were given daily injections of 0.1-0.2 cc. corpus luteum extract. Masculine attitude appeared. Daily injections of 0.1 cc. corpus luteum extract into infantile, castrated ♂ rats for 12 days caused the corpus cavernosum to develop, the typical penis being present in 18 days. Thus, in addition to the hormones specific for the ♀ sex, the ovaries develop one acting specifically for the ♂, located in the lutein tissue.

9855. **STILL, EUGENE U. Studies on the physiology of secretin. I. On the preparation and isolation.** *Amer. Jour. Physiol.* 91(2): 405-408. 1930.—A method is described for making a very potent secretin preparation, which, so far as tested, has no effect upon the body except to stimulate the flow of pancreatic juice and bile. —*E. U. Still.*

9856. **STSCHEDROWITZKY, S. G., und S. A. SELTZER. Über die regulierende Rolle der Milz im intermediären Stoffwechsel.** *Zeitschr. Ges. Exp. Med.* 76(3/4): 369-379. 1931.—Metabolic tests on 11 dogs for 1-2 yrs. after splenectomy showed that thyroid function rose, judging by the serum-atropine reaction. A permanent lymphocytosis appeared. The reserve alkali of the blood was elevated for months; the blood sugar level decreased and remained so for the duration of observation. The blood cholesterol was high for 2-3 mos., then decreased to the preoperative level. The blood Ca rose; it decreased in both normal and splenectomized dogs when spleen was fed. The blood cholesterol and sugar were not influenced in normal dogs by feeding spleen; in the splenectomized they approached or attained preoperative values. The authors believe that the spleen produces a true hormone and is intimately associated with all true incretory glands.

9857. **TADA, SABURO. Wirkung des Nebennieren-, Pankreas- und Hypophyseninkrets auf die Bewegungen des überlebenden Darms von Kaninchen mit Funktionsstörung der Schilddrüse.** *Tohoku Jour. Exp. Med.* 14 (4): 400-414. 1929.—Rabbit intestine was suspended in Tyrode solution; Magnus' method was used in studying intestinal movements. A solution of adrenalin of 10^{-7} to 2×10^{-7} still inhibited the intestine of normal rabbits, whereas solutions of 5×10^{-7} to 10^{-6} were required for intestines of thyroid-fed rabbits. Intestine from thyroidectomized rabbits showed the same sensitiveness to adrenalin as normal intestine. Insulin had less effect on the intestine of thyroid-fed than of normal rabbits, whereas the opposite was found for pituglandol. Thyroidectomy caused no change in the reaction of the intestine to these two hormones.—*G. T. Cori.*

9858. **TADA, SABURO. Wechselbeziehungen zwischen Nebennieren-, Pankreas- und Hypophysenhormonen in ihrer Wirkung auf den überlebenden Kaninchendarm.** *Tohoku Jour. Exp. Med.* 15(1/2): 50-69. 1930.—Insulin augments the inhibitory action of adrenalin on the isolated intestine of rabbits. Pituglandol antagonizes the inhibiting action of adrenalin. Pituglandol stimulates the contractions of the isolated intestine; this effect is antagonized by insulin.—*G. T. Cori.*

9859. **ZAVŘEL, JAN. Untersuchungen über den Einfluss einiger Organextrakte auf Wachstum und Entwicklung der Chironomiden.** *Zeitschr. Wiss. Biol. Abt. D. Wilhelm Roux' Arch. Entwicklungsmech. Organ.* 121 (4): 770-799. 6 fig. 1930.—The normal development of *Chironomus clavaticrus* lasts a whole year in central Europe, the parthenogenetic ♀♀ appearing from June to September. In England, according to Edwards, there are 2 generations a year, 1 in May and the other in August, the latter with a shorter (2½-3 mos.) developmental period. Zavrel produced changes in growth and development by thyroid and thymus feeding, and by increased temperature (25°-30°). Young or medium-sized larvae fed with dried thyroid or thymus grew more rapidly than the controls, especially at the beginning of the experiment, but metamorphosis was not noticeably hastened. Early summer larvae fed with thyroid or thymus extract (or kept at a high temperature) grew very rapidly, and metamorphosis was hastened by 1 or 2 months. Late summer or autumn larvae, fed with thyroid or thymus extract or kept at a high temperature, grew more rapidly at the beginning of the study than did the controls, but the winter arrest of growth was not thereby warded off. The embryo development of fresh-laid eggs was greatly delayed by thyroid extract, but, placed in fresh water, the embryos soon recovered, and the growth of the larvae from such sometimes exceeded that of the controls. Meat extracts had little stimulating effect or none.—*From author's abstract (transl.).*

ANIMAL PHYSIOLOGY

KIDNEY, URINE, AND EXTERNAL SECRETIONS

9860. [ASRATÎAN, ESRAS.] АСРАТЯН, ЭЗРАС. Утомляемость почек. [Fatigue of the kidneys.] [German summary.] Известия Научного Института имени П. Ф. Лесгафта, СССР. (*Bull. Inst. Lesshaft, URSS.*) 16 (1/2): 243-271. 1930.—Half of one kidney of a dog was extirpated about a year before the experiment. When the kidney had fully recovered from the operation, addition of water to a normal diet was found to lead through a phase of polyuria to a marked difference in the diuresis of the kidneys, the half kidney being deficient. Similar results were obtained with chlorides and urea added to any diet. In this phase (which lasted for 1-2 hours) the urine of the kidney which had been operated on was characterized by high concentrations of chlorides, creatin, urea, and abundant precipitates and albumins. Addition of urea to a normal diet presented an exception; the urine, while having a high creatin content, showed a lower concentration of urea than the urine of the control kidney, especially if NaCl was administered at the same time. A milder form of the same phenomenon was observed after some time in the control kidney also. Addition of water to a diet low in chlorides showed no difference in the diuresis of the kidneys, the control kidney showing even some decrease in diuresis. These facts lead to the conclusion that the kidneys can be fatigued.—*S. A. Corson.*

9861. **BASCH, FELIX. Die kapillare Resistenz.** *Zeitschr. Kinderheilk.* 49 (4): 446-453. 1930.—Diuresis is greater, as shown by 2-hr. tests, when the subject is in bed than when upright, because in the standing posture the hydrostatic pressure on the capillary walls, which promotes escape of fluid from the blood into the tissues, corresponds to the height of the individual, while in the horizontal position this pressure is reduced to the minimum. The difference between the orthostatic and horizontal diuresis is not great in normal subjects, because of the normal resistance of the capillary walls; but in renal patients the weakening of the capillary walls leads to edema and lessened diuresis. Basch makes these facts the foundation for a study of the pathogenesis of anaphylactoid purpura. On 2 successive days 400-600 cc. of warm tea with saccharin was administered to the subject, and the urinary excretion within the next 2 hrs. measured. On 1 of these test days the 2 hrs. were spent in bed; on the other day in the upright position. The test was given to 12 subjects, 2 normal, 1 with urticaria, 1 with leukemic myelosis and 8 with purpura; on some the test was repeated. The normal controls showed the slight difference mentioned between orthostatic and horizontal diuresis; all the others showed the marked difference characteristic of damaged capillary function, except after cure, which was signalized by the normal slight difference.

9862. **BAYLISS, L. E., and ARTHUR M. WALKER. The electrical conductivity of glomerular urine from the frog and from Necturus.** *Jour. Biol. Chem.* 87 (3): 523-540. 1 fig. 1930.—A cell has ben designed which enables accurate estimation of electrical conductivity of fluids in volume as small as 0.5 c. mm. Comparisons have been made between the electrical conductivities of blood plasma and ultrafiltrates and between those of blood plasma and glomerular urine obtained from the frog and from *Necturus maculosus.* These comparisons show that in respect of total electrolyte concentration the glomerular urine from both species is indistinguishable from an ultrafiltrate of plasma.—*Author's summary.*

9863. **BIEDERMANN, W. Vergleichende Physiologie des Integuments der Wirbeltiere. 5 Teil. Die Hautsekretion.** *Ergebnisse Biol.* 6: 427-545. 33 fig. 1930.—The secretory processes in the integument of vertebrates are manifold and of great interest. Their variability is due not only to differences in external living conditions (water or land life), but depends above all on the diverse functions of the skin secretions. In many fish the skin secretions are present as a well developed mucous membrane protective in nature. In amphibia (toads and salamanders) a poisonous secretion is often produced by the skin. A relatively small rôle is played by the skin secretions in the Sauropsidia. In mammals, however, the sweat glands take part in the process of heat regulation and also protect certain parts of the skin from drying. Skin secretions also serve for oiling the hair, for the production of specific odoriferous materials, and finally for the production of milk.—*Z. K. Cooper.*

9864. **BIETER, RAYMOND N., and ARTHUR D. HIRSCHFELDER. The rôle of the glomeruli as the preferential route for excretion of phenolsulphonephthalein in the frog's kidney.** *Amer. Jour. Physiol.* 91 (1): 178-200. 3 fig. 1929.—[Experiments on 16 frogs.] Injection of the glomeruli through the renal portal vein in the frog is easily accomplished, and, on an average, shows about a 30% glomerular injection in the whole kidney, in some cases reaching twice that figure. The observation that phenolsulphonephthalein, when added to the renal portal blood or perfusate, is eliminated in the urine, as first demonstrated by Rowntree and Geraghty, is confirmed. The mechanism of this elimination parallels the accessibility of the glomeruli to renal portal blood, and it is absent when the renal portal blood does not enter the glomeruli, as shown by simultaneous renal portal india ink injections. The accessibility of the tubular capillaries to the renal portal blood flow appears to have no marked relation to the excretion of phenolsulphonephthalein injected as described above. A new technique for the study of kidney function in the frog is described, by which substances injected into 1 or the other blood supply can then reach more or less of the glomeruli in the 2 halves of the kidney and thus result in varying secretions. The frog's kidney submitted to this procedure is able to concentrate phenolsulphonephthalein at least for 15-20 min., thus indicating that the kidney is functioning in a manner close to normal during this time. These results tend to confirm the conception of Nussbaum, that in the tubular capillaries a complete mixing of renal arterial and renal portal venous blood occurs, and it is still further confirmed by Richards and his co-workers (1927-28). These results also confirm Adami's criticism of Nussbaum's experiment; namely, that after ligation of the renal arteries in the frog, the glomeruli may still obtain blood, probably from the renal portal vein. Glomerular elimination of phenolsulphonephthalein in the frog's kidney appears to be the method of preferential excretion.—*Authors' conclusions.*

9865. **BIETER, RAYMOND N. The effect of the splanchnics upon glomerular blood flow in the frog's kidney.** *Amer. Jour. Physiol.* 91 (2): 436-460. 1 fig. 1930. —Intermittency of glomerular blood flow and intermittency of capillary flow within the glomerulus in the normal frog's kidney, as first reported by Richards (1922) is again confirmed. Immediately after splanchnic section in the frog, this intermittency, for the most part, disappears. At 3 hrs. after splanchnic section in 2 cases

intermittency was again seen in several small fields of glomeruli, but the rest periods were no longer than 30 sec. Section of the splanchnics, as an acute effect, results in an increase of glomeruli showing active blood flow. Various measures such as pinching the ureter, applying an irritant locally, both externally and internally, and edema fluid let into the general circulation, result in reflex arrest of glomerula flow. This is prevented by splanchnic section and cocainization of the part stimulated. The reflex arrest produced by $HgCl_2$ in the ureter and collecting ducts appears more pronounced than the reflex arrest coming from within the kidney tubules. These experiments show the marked effect of the splanchnics upon glomerular blood flow and in part explain how local anesthesia and section of renal nerves produce beneficial results in reflex oliguria and anuria.—*Author's conclusions.*

9866. BIETER, RAYMOND N. The reabsorptive function of the tubule in the frog's kidney. *Amer. Jour. Physiol.* 93(2): 574-587. 1930.—A technique of injecting various substances, by means of the ureter, into the tubules of the frog's kidney for studying reabsorption, is described. Using Richards' method of direct observation, changes produced in the solutions in the lumina of the tubules and in the epithelium can be noted. As pyelo-venous backflow does not occur within the normal frog's kidney, it is thought to be safe to use this method for intratubular injections. Phenolsulphonephthalein when injected into the proximal and distal convoluted tubules in the normal frog's kidney is reabsorbed. At least a part of this reabsorbed dye is excreted by the opposite kidney. Phenolsulphonephthalein when injected into the ureter and larger collecting ducts also shows this reabsorption and resulting excretion by the opposite kidney, but to a much less extent. Sodium indigosulphonate, indigocarmine and trypan blue, injected in a similar manner, are reabsorbed to only a very slight degree. When a solution of 1 of the above dyes is injected into the distal convolutions, concentration begins immediately. Precipitation of the dye particles within the tubular lumen from solutions of 0.25-0.05% begins in 5-20 min. With solutions of 0.25% the precipitation is almost complete in 20-30 min. This undoubtedly occurs primarily from reabsorption of water. During this process of concentration, the diameter of the tubular epithelium appears increased, as if the cells were taking up some substance to increase their bulk. $HgCl_2$ in dilute solutions inhibits the concentration of the dyes within the lumen of the tubules described above. Following the application of this salt, precipitation from a solution of 0.25% begins in 25-35 min. and in some cases is not complete in 90 min. $HgCl_2$ again injected into the convoluted tubules produces a marked inhibition of what appears to be reabsorption of water and phenolsulphonephthalein. The inhibition of tubular reabsorption of both water and dyes produced by $HgCl_2$ tends to confirm the findings of Lepine and his students, carried out on mammalian kidneys, and possibly also those of Bainbridge, Collins and Menzies obtained through a different route. The present results fit into and support Cushny's "modern theory of kidney function" more satisfactorily than they do any alternative theory. —*Author's conclusions.*

9867. BIETER, RAYMOND N. The secretion pressure of the aglomerular kidney. *Amer. Jour. Physiol.* 97(1): 66-68. 1931.—Experiments on 7 toad fish show that in the aglomerular kidney the secretion pressure taken in the ureter can be greater than the dorsal aortic blood pressure.

9868. BILLI, A. Alterazioni istologiche e funzionali dell'intestino nella soppressione della funzione renale. [Histological and functional alterations in intestine following suppression of renal function.] *Boll. Soc. Ital. Biol. Sperim.* 5(4): 595-597. 1930.—Alterations of the intestinal mucosa, especially in the cecum, are accompanied by an abnormally increased intestinal impermeability in rabbits and rats after nephrectomy or bilateral ligation of ureters.—*M. Comel.*

Pharmakol.* 140(1/2): 118-128. 7 fig. 1929.—Decolorizing urine with charcoal changes the pH in a complex manner. Appreciable errors in its determination may occur if the CO_2 factor is not considered, particularly if the urine reaction is alkaline. In this case the reaction and buffering of the urine resembles that of blood. The daily maximum fluctuation of the pH in health is smaller than usually believed for the H-ions of dissolved CO_2 depress the alkaline peak.—*E. M. MacKay.*

9870. BRAND, ERWIN, MEYER M. HARRIS, and SOL BILOON. Cystinuria. The excretion of a cystine complex which decomposes in the urine with the liberation of free cystine. *Jour. Biol. Chem.* 86(1): 315-331. 1930.—The mechanism of cystinuria is studied by a new approach to the problem. Using the Sullivan reaction for quantitative estimation of cystine in cystinuria urine evidence is presented which indicates that in this condition a cystine compound is excreted and this compound decomposes in the urine with the liberation of free cystine. A case is reported in which a urinary calculus was diagnosed as being composed of cystine. Free cystine in the urine is not essential to the diagnosis of cystinuria and the term cystinuria should be restricted to cases with transient high neutral S excretion.—*J. H. Barach.*

9871. BROWN, MARION, and C. G. IMRIE. The influence of creatine on the excretion of phosphates by the kidney. *Jour. Physiol.* 71(2): 222-228. 1931.—Creatine dissolved in caffeine citrate, introduced into the duodenum of 10 cats under chloralose, and creatine in normal saline intravenously injected into 6 decerebrate cats (normal saline alone in 2 controls), was followed by a temporary reduction in the output of phosphates by the kidney, the reduction being most marked when larger quantities of creatine were retained (more than 100 mgm./kgm. of body wt.). The concentration of P in the blood may be above the normal when the phosphates in the urine are absent.

9872. BRULL, LUCIEN. Polyurie expérimentale. *Rev. Belge Sci. Méd.* 2(2): 121-153. 13 fig. 1930.—Experiments were carried out on 57 dogs (35 hypophysectomized, 17 with lesion of the tuber, of which 5 lesions preceded hypophysectomy, 10 controls). There were 2 unsuccessful experiments (cases in which hypophysectomy had induced hemorrhage interrupting the experiment). Immediately following or within the next few hrs. after hypophysectomy, an intense polyuria with arrest of chlorid excretion was provoked in narcotized dogs. This phenomenon could not be reproduced by cauterization of the tuber. Injection of pituitrin suspended the effects of hypophysectomy. The fact that all or part of the pars tuberalis is not removed in hypophysectomy goes to show that the latter plays a compensatory secretory rôle in the absence of other parts of the gland. The lesions produced have been anatomically controlled.

9873. BYKOW, K. M., und I. A. ALEXEJEW-BERKMANN. Die Ausbildung bedingter Reflexe auf die Harnausscheidung. II. Bedingte Reflexe bei denervierter Niere. *Pflüger's Arch. Ges. Physiol.* 227(3): 301-308. 1931.—A conditioned reflex of diuresis was established by injection of water into the rectum (1 dog, ureters opening on the abdomen); after the reflex had disappeared, the right kidney was denervated, the left serving as control. Denervation exerted no noticeable influence on diuresis, on the presence or disappearance of the conditioned reflex, on its reestablishment, or on the effect of inhibitory process due to external agents (presence of cat, loud sound). The reflex route of the conditioned diuresis has a nervous and a humoral component.

9874. CANNY, A. J., E. B. VERNEY, and F. R. WINTON. The double heart-lung-kidney preparation. *Jour. Physiol.* 68(4): 333-347. 2 fig. 1930.—The 2 kidneys of a dog are perfused by 2 heart-lung preparations so arranged that the blood of the 2 circulations may mix

freely or be completely separated as desired. Measured by blood flow, urea, and chlorides, the response of the 2 kidneys is closely similar. Complete separation does not interfere with parallel response either to changes of perfusion pressure or to addition of caffeine or pituitary extract. The parallel response, indicating the same physiological state, makes it possible to express quantitatively the effects of any given change in perfusion conditions. —*F. P. Knowlton.*

9875. CHABANIER, H., C. LOBO-ONELL, et E. LÉLU. Étude sur les diurèses aqueuses et salines. I. Essai sur le méchanisme de l'élimination de l'eau. *Jour. Physiol. et Path. Gén.* 28(4): 841-853. 1930.—In the rabbit, a sudden diuresis tends to raise the urinary pH, and, conversely, arrest of the diuresis is accompanied by a decreased urinary pH. This is explained by the retention of acids or bases, respectively, by the renal cells, and is associated with alterations in the iso-electric point of the proteins of the kidney tubules.—*W. R. Fearon.*

Essai synthétique sur la sécrétion rénale de l'eau. *Jour. Physiol. et Path. Gén.* 29(1): 52-61. 1931.—Two factors are recognizable in polyuria however produced: a tubular effect, depending on alterations in the hydration-capacity of the proteins of the tubule, and a glomerular effect, due to increase of osmotic pressure within the capsule. This latter condition is seen in water diuresis, and is ascribed to acid-retention by the kidney, since it is characterised by the shifting of the urinary pH towards alkalinity. The extension of the theory involves the recognition of tubular secretion as well as absorption, and glomerular secretion as well as filtration.—*W. R. Fearon.*

9877. CHABANIER, H., C. LOBO-ONELL, et E. LÉLU. Études sur les diurèses aqueuses et salines. III. Aperçu critique sur les théories de la sécrétion rénale en général. *Jour. Physiol. et Path. Gén.* 29(1): 62-71. 1931.—During physiological spontaneous secretion, the activity of the tubules is much greater than that of the glomeruli in the production of the urine. Any sudden load on the kidney, due to the normal urinary constituents, is met by secretion on the part of the tubules. All changes in the iso-electric point of the tubular proteins towards acidity tend to provoke a retention of anions and a resultant glomerular polyuria. The relationship of these conclusions to the older theories of renal secretion is discussed.—*W. R. Fearon.*

9881. EBBECKE, U. Über Gefässreaktionen der Niere und den Antagonismus von Glomerulus- und Tubulusdurchblutung. *Pflüger's Arch. Ges. Physiol.* 226(6): 761-773. 4 fig. 1931.—Freshly excised kidneys of frogs (*Rana temporaria*), injected and examined by the fluorescent method of Ellinger, show 3 types of blood supply: (1) pale kidney, with few or no injected glomeruli and only major vessels patent; (2) glomerular kidney, with practically all glomeruli injected, but other vessels no more abundant than in pale kidney; (3) hyperemic kidney, with entire tubular vasculature injected but glomeruli visible only as shadows if at all. Pale kidney is the resting state: it is usual in frogs kept cool and dark, but it is sometimes seen even after injection of hypo-, iso-, or weakly hypertonic solutions. Glomerular kidney is more usual finding after such injections. Only after strongly hypertonic solution is hyperemic kidney found. Urea, caffeine, $HgCl_2$ yield either glomerular or hyperemic type, with tendency to the former with smaller doses or briefer time of action. Dry frogs always show hyperemic picture. Results point to rhythmic alternation between glomerular activity (ultrafiltration) and tubular (concentration), so as to permit time for latter process to be completed. Regulation is probably chemical, through liberation of histamine from tubular cells when concentration of absorbed materials has become high enough to cause irritation; alternation of glomerular and tubular circulation is probably dependent upon axon reflexes. Experiments on mice, guinea-pigs, rabbits, cats and dogs indicate the same sort of mechanism in mammals, but picture is not as clean-cut. Diabetes insipidus may be due to loss of regulation of glomerular circulation so that time for concentration in tubules is not allowed.—*C. F. Schmidt.*

9882. EBBECKE, U. Über den Flüssigkeitstransport in den Harnkanälchen mit Beobachtungen über die Flimmerbewegung in den Nephrostomen der Froschniere. *Pflüger's Arch. Ges. Physiol.* 226(6): 774-780. 1931.—Ciliary activity in nephrostome of ventral surface of frog's kidney continues for hours after excision of kidney: it is inhibited (reversibly) by N/200 KCN and by 1% urethane, concentrations which are known to interfere with urine formation. Since cilia are present in frog's tubules; it is probable that they propel fluid, thus lowering pressure in Bowman's capsule, or emptying tubule if glomerular filtration ceases. In mammals smooth muscle of papillae exerts a similar influence though cilia are absent. Consequently if tubular cells continue active when the glomerulus rests and the tubular lumen is empty, they cannot be reabsorbing at this time.—*C. F. Schmidt.*

Kinderheilk.* 36(1): 57-64. 1927.—With the suckling an increase in food-fat leads to an increased C/N quotient and is generally accompanied by an absolute increase in carbon excretion. Increase of carbohydrate alone does not have this effect. In rickets the quotient is extraordinarily increased, to between 3-10. Increase in food fat affects the quotient of the rachitic infant more than that of the normal. Insulin lowers the quotient.—*Author's summary (transl. by M. E. Collett).*

9884. EDWARDS, J. GRAHAM. The renal tubule and glomerulus. *Amer. Jour. Physiol.* 95(2): 493-510. 3 pl., 1 fig. 1930.—Data are presented showing the locus of concentration of dyes and Fe salts within the lumen of the distal convolution of the renal tubule of 3 classes of vertebrate kidneys. The site of water reabsorption is indicated by the presence of these substances in highly concentrated form only in the lumen of this convolution. Special methods were devised to show convincingly the locus of this concentration, and the precise conditions under which this concentration occurs or may be induced are set forth. Kidneys whose visible glomeruli are inactive, permitting the lumina of tubules connected with them to become filled with concentrated substance, are quickly washed free of it by reactivating these glomeruli. The significance of the rapid release of fluid from the glomerulus is suggested and its effect on the relative patency of the lumen of the tubule is shown. The rate of excretion by the tubule is relatively slow and uniform with or without continuous glomerular activity as shown by the careful inactivation of a single glomeru-

lus in a highly functional kidney. New methods are described for inactivating a given glomerulus as well as in part for studying segmentally, without sectioning, the tubule with which the inactivated glomerulus is connected. Mechanical distention with fluid of the lumen of the tubule flattens the epithelium comparably with that observable in a diuretic kidney. The functional significance of this alone is doubtful. Certain experiments on the frog involving ureteral injections indicate possibilities for a pyelovenous backflow.—*Author's summary.*

9885. **ELAUT, L. J. S.** Bijdragen tot de urologie van zwangeren. [Urologic data of pregnancy.] 127pp. 2 pl. Thesis—University of Amsterdam, 1929. Pr. 4.30 ure.

9886. **EMBDEN, G., und H. SCHUMACHER.** Über die Ammoniakbildung in der Niere. *Pflüger's Arch. Ges. Physiol.* 223(4/5): 487-495. 1929.—After rapid cooling in liquid-air, the normal ammonia-content of rabbit kidney is 2 mgm. %. Kidney tissue, disintegrated in liquid-air, on keeping at 37°C. in 2% Na_2CO_3, increases in ammonia-content up to 14-18 mgm. %, after 3.5 hrs. Ammonia-formation ceases within 2.5 hrs. After destruction of deaminising enzymes, a varying amount of this ammonia (av. 60%) is liberated on addition of an enzyme that liberates ammonia from muscle-adenylic acid only. Caffeine diuresis markedly diminishes the content of ammonia precursors, but restitution takes place in 1-2 days.—*W. R. Fearon.*

9887. **FARKAS, G. von, [et al.].** Nierenstudien. I. [G. v. FARKAS, und C. SELLEI.] II. Über die Wirkung harnfähiger Substanzen und deren Konzentration auf die Quellung der Nierenzelle. III. [G. von FARKAS, und F. von BORBÉLY.] Über die Wirkung der Wasserstoffionen auf die Quellung der Nierenzellen. *Zeitschr. Ges. Exp. Med.* 70(5/6): 696-707; 708-719. 3 fig.; 720-724. 2 fig. 1930.—I. An introduction, with discussion of the toxicity of urinary substances and the changes in their concentration on the renal parenchyma. The study of mouse and guinea-pig renal tissue in Warburg's apparatus in various media showed that urea, $CaCl_2$ and Na_2SO_4, even in concentrations much lower than those in urine, were highly toxic; the duration of life of the pieces was much shortened and the respiratory quotient sank. The displacement of the H toward the acid side was also toxic for renal tissue; in a medium of pH 5.36 it lived only 50 min., less than half its survival in pH 7.35 (pure normosal). The cessation of respiration was not of the nature of narcosis but an irreversible process leading to the death of the renal cells. The duration of life of hepatic and muscular tissue in the Warburg apparatus was much shorter than that of renal tissue; in solutions of half and double isotonic concentration the life span of liver and muscle contracts strongly, that of kidney only slightly. Hence it appears that renal cells are distinguished, (1) by their great resistance to changes in osmotic pressure and (2) great sensitiveness to urinary constituents. It seems probable, therefore, that urea and the ions studied, H^+, SO_4^{--}, Ca^+, Cl^- and Na^+ are concentrated outside of the renal cells, and it is possible that the fluid streaming abundantly through the renal cells is approximately constant in composition and highly variable only in osmotic pressure.—II. These studies were made on the kidneys of "many" rabbits and a few cats and dogs. Isotonic solutions of urea, NH_4Cl, KCl, Na_2CO_3, dextrose, NaCl, normosal, NaH_2PO_4, $CaCl_2$, and $MgCl_2$ produced swelling of the renal cortex of the 24-hr.-fasting rabbit in 2 hrs.; NaH_2PO_4 and Na_2SO_4 produced a shrinkage. The greatest swelling was produced by distilled water and urea; the amount of swelling caused by the other substances was in descending order. Henle's loops and the medulla also swelled in these solutions, but less than the cortex; but in Henle's loops the order of activity was different, the swelling in urea and dextrose being less, in KCl, $CaCl_2$, and NaCl greater than would correspond to the swelling of the cortex in these same media. This swelling cannot be caused by the death of the tissue, since, on the one hand, it is marked in the non-toxic solutions of NaCl and normosal, and, on the other, in the toxic solutions of urea and Na_2SO_4 it varies from +90% to −3%. The swelling of the kidney in isotonic solution is explained by its varying permeability for the various substances in question. The renal cortex is capable of absorbing 60-70% of its original weight in normosal solution without losing its vitality, a result contrasting with the toxicity of solutions producing swelling of spleen, liver or muscle. —III. Solutions of pH varying from 8 to 3 produced, on renal cortex of various animals, a swelling in certain concentrations (pH 4-4.5) and a shriveling with increasing acidity. This occurred in all media except Ca and PO_4 solutions, in which between 6 and 4 a marked swelling was observable. With all other ions a decrease in weight occurred, especially noticeable beyond pH 3. These phenomena become marked only at pH 4.5 or less, which is an acidity never reached in the blood or the urine; hence conclusions drawn from these observations as to renal physiology must be very guarded. It had already been shown, however, that even pH 5.36 is very injurious to the renal cortex. Hence it is concluded that the concentration of H ions takes place outside of the protoplasm of the renal cells, and that the cell-membrane of the lumen of the tubuli is impermeable for H ions. Hence only the very slight physiologic variations of pH appear in position to exercise any influence on the swelling of the parenchyma; and the results of these researches are even more difficult to interpret in their bearing on the renal medulla.

9888. **FREEMAN, BENJAMIN, A. E. LIVINGSTON, and A. N. RICHARDS.** A second series of quantitative estimations of the concentration of chlorides in glomerular urine from frogs. *Jour. Biol. Chem.* 87(3): 467-477. 1930.—The chloride concentration of glomerular urine from frogs was analyzed by the nephelometric method of T. W. Richards and compared with the chloride concentration of the fluid (perfusion fluid or plasma) from which the urine was derived. In 19 perfusion experiments the concentration of the two fluids proved to be substantially the same, and in only 7 of the 20 experiments with intact circulation was the glomerular urine hypertonic to the plasma by an amount which exceeded the error of the method (10%). The infrequency with which this difference was found, the discovered likelihood that the glomerular urine might have evaporated during its manipulation, and the results of other comparisons between glomerular urine and plasma published in sequence with this paper, make it seem unlikely that the glomerulus possesses the power to "secrete" chlorides.—*A. M. Walker.*

9889. **FØLLING, A.** On the site of the ammonia production. A note. *Skand. Arch. Physiol.* 61(1/3): 23-26. 1931.—More evidence is presented to show that as long as the urine is on the acid side of pH=7.8, more ammonia is found in the urine than is filtered from the blood in the same time. This is not due to a diffusion from alkaline blood into acid urine for the concentration of undissociated ammonia is about 10 times greater in the urine than in the plasma.—*W. J. Meek.*

9890. **FREY, E. K.** Die Kreislaufwirkung eines neuen von der Niere ausgeschiedenen Stoffes. *Arch. Klin. Chir.* 148: 634-650. 11 fig. 1927.—A substance prepared from urine when injected intravenously (1/100 mgm. per kgm.) increases the pulse rate and decreases diastolic pressure, even after section of the cardiac nerves. It speeds up a slow heart and makes an irregular heart regular. It causes an increased pressure in the pulmonary circuit and a decreased pressure in the systemic. The kidney volume parallels the carotid pressure, the volume of the legs and arms varies inversely as the carotid pressure. This substance is absent from urine in uremia and produces edema of the lungs and brain. It is not histamine.—*M. E. Collett.*

9891. **GEDDA, LUIGI, e GIUSEPPE CHIESA.** La diuresi diatermica. [Diathermic diuresis.] *Arch. Sci. Med.* 54(10): 717-732. 12 fig. 1930.—Following diathermic applications on the kidney region, the immediate response is a rise of diuresis, the urine being more dilute. The urine eliminated in 24 hrs. in some

cases was more concentrated, in others more dilute, in others showed fluctuations.—*M. Comel.*

9892. GOIFFON, R. Variations du pH urinaire par modifications du rapport entre l'ammoniaque et l'acidité de titration, dans les émissions fractionnées. *Compt. Rend. Soc. Biol.* 106(10): S0S-S10. 1931.—Plotting the pH against the ratio acidity/NH_3, determined from hourly samples of urine from 6 normal subjects, showed an indirect inverse relation between these quantities. The pH is not a good index for the effort of the kidneys in acid elimination. The urinary pH can be used to indicate the direction of modifications but not as their measure. Since the pH is the most variable element of urinary acidity in the course of a day, the alkalinity or acidity of a single sample taken at random is meaningless.—*E. Weiner.*

9893. GOLDBERG, MARGARETE. Der Einfluss des vegetativen Nervensystems auf die renale Glykosurie. [The influence of the vegetative nervous system on renal glycosuria.] *Zeitschr. Ges. Exp. Med.* 59(3/4): 468-473. 1928.—The action of atropine and ergotamine on the phloridzin glycosuria, considered to be of renal origin, was studied. Both these drugs proved to have an inhibitory effect. The inhibition was more pronounced when the vegetative drugs were given with phloridzin simultaneously. This study, carried out on 9 men, demonstrates that renal glycosuria is influenced by the vegetative system. It also suggests reservation with regard to the subdivision of the vegetative system into 2 antagonistic components; for ergotamine depressing the sympathetic, and atropine inhibiting the vagus, and thus supposed to induce, respectively, vagotonia and sympathicotonia, had an identical pharmacological effect. —*S. Katzenelbogen.*

9894. GRAFFLIN, ALLAN L. Urine flow and diuresis in marine teleosts. *Amer. Jour. Physiol.* 97(4): 602-610. 1931.—Evidence from work on the sculpin and toadfish indicates that the normal urine flow is below 4 cc. per kgm. per 24 hrs., much lower than older figures. The normal urine of these 2 species was almost invariably free from chloride and relatively high in total N. Injury to the skin was identified as a principal factor in causing the abnormally high flows encountered under experimental conditions, associated with a marked rise in chloride concentration in plasma and urine. Diuresis typically increased to a peak, then decreased with approaching death, the low chloride and high total N concentrations present in the urine in the early stages becoming rapidly reversed.—*Author's summary.*

9895. GREMME, A. Zur Physiologie der oberen Harnwege in der Schwangerschaft. (Untersuchungen über die Farbstoffausscheidung im Vergleich mit dem intravenösen Pyelogramm.) *Arch. Gynäkol.* 145(1): 132-149. 8 fig. 1931.—In 6 women in 2-4 mo. of pregnancy and in 34 in 5-10 mo. chromocystoscopy and the pyelogram showed passive dilatation and delay in emptying of the upper urinary tract caused by compression of the ureter between the psoas and the uterus which becomes possible only after hypotony of the ureter. The effect is usually overcome by active ureteral peristalsis or displacement. In the dilated renal pelvis and ureter above the point of compression there is accumulation of urine which is emptied usually in the form of marked hypersecretion when compression yields or there is sufficiently strong peristalsis.

9896. GRUBER, CHARLES M. The uretero-vesical valve. *Jour. Urol.* 22(3): 275-292. 3 fig. 1929.—The uretero-vesical orifices were studied in the excised bladders of human, pig, dog, cat, rabbit and monkey. The intra-vesical ureter was found to serve as a true valve. It is not a sphincter dependent upon muscle tone or muscle contraction, but acts passively. Cutting away the uretero-vesical valve (intra-vesical ureter) was found to permit reflux of fluid from the bladder into the ureter in all bladders tested, except in one human bladder with very thick wall. In urinary bladders in which the valves were normal (not sclerosed, edematous, partly destroyed or inflamed) regurgitation did not occur in man, cat, dog, pig and monkey, unless the injection pressures were excessive and the volume of fluid injected exceeded that found normally in the bladder. Stretching the bladder mucosa by injecting into the bladder excessively large amounts of fluid under high pressure shortened the valves and in many instances rendered them incompetent. Contraction of Bell's muscle simultaneously pulls the uretero-vesical valve toward the urethra and opens the internal urethral sphincter. —*C. M. Gruber.*

9897. HALLAUER, C. Klinische und experimentelle Untersuchungen über den Lysozymgehalt im Bindehautsack und in der Tränenflüssigkeit. *Arch. Augenheilk.* 103(1/2): 199-215. 1930.—In 120 clinical cases the lysozyme content of the tears was estimated; a. in clinically normal conjunctivae, and b. in chronic and acute inflammation of the conjunctiva and cornea. It was only diminished in acute inflammatory conditions of the anterior segment. The amount of the lysozyme in the tears depended upon the activity of the lacrimal gland. Atropine diminishes the secretion of tears and leads to an increase in the lysozyme content while pilocarpine increases the secretion and leads to a fall in the amount of lysozyme. The significance of this substance as a protection against bacteria is discussed and its therapeutic possibilities suggested.—*F. H. Adler.*

9899. HEILMEYER, LUDWIG, und WILLY OTTO. Klinische Farbmessungen. IX. Die Analyse des Harnrestfarbstoffs, ein Beitrag zur Klärung der Urochromfrage. *Zeitschr. Ges. Exp. Med.* 74(3/4): 490-513. 1930. —The predominant urinary coloring matter of normal urine designated by most authors as "urochrome," is not a single compound. By saturating the urine with $(NH_4)_2SO_4$ it can be separated into 2 parts, Urochrome A and B which can be differentiated with certainty by the absorption spectrum. Further analysis of Urochrome A showed that this pigment portion is not individual, since it consists of two fractions, one easily soluble, the other poorly soluble in butyl alcohol. Both of these fractions of Urochrome A are extraordinarily susceptible to acids. Changes due to oxidation consist in that the typical pigment curve rises to a higher level, and is flatter in its descent. It is therefore not a simple new production of pigment from chromogen, but rather a simultaneous transformation of the pigment with oxidation of Urochrome B; no increase in color occurs; there occurs only a flattening of the curve, which appears to the naked eye as fading. The distribution of both Urochromes in the urinary pigment concentration, is Urochrome A about 26-42%, Urochrome B—50-74%. Urochrome B appears to be the predominant pigment in normal urine. Spectrophotometric controls of the differentiating tests with lead acetate indicate that this method is useful for quantitative as well as qualitative estimations of the normal urinary pigment. Further investigations of Urochrome B are being made, especially as to whether it is a single pigment or a mixture of pigments.—*Authors' summary (transl. by M. Lederer).*

9900. HEMINGWAY, A. Some observations on the perfusion of the isolated kidney by a pump. *Jour. Physiol.* 71(2): 201-213. 2 fig. 1931.—In the apparatus described the perfused kidney (dog) was supplied with blood by a pump, the perfusion rate being measured while venous blood was collected and perfused under hydrostatic pressure through isolated lungs. In 10 experiments the lungs were removed from the perfusion circuit after a steady renal blood flow had been established, without development of toxic properties. Over 40 experiments were performed in which the kidney excreted typical urine.

9901. HIMWICH, H. E., and M. A. ADAMS. Studies in glandular metabolism. II. The carbohydrates of resting and secreting submaxillary glands. *Amer. Jour.*

Physiol. 93(2): 568-573. 1930.—The anaerobic cleavage of glycogen as a possible source of energy for the secreting submaxillary gland was studied, in 4 series of experiments on dogs under amytal anesthesia. In the 1st and 2nd series, the carbohydrate balance of the glands was studied. The 3rd and 4th series consisted of studies made of the blood and saliva of resting and stimulated glands. Since it was impossible to demonstrate an increased production of lactic acid during secretion of the submaxillary gland, the authors were forced to the conclusion that glycolysis does not serve as a source of glandular energy. It is to be noted, however, that if the lactic acid produced by glycolysis was entirely reconverted to glycogen or oxidized as soon as it was formed, it could not be detected by the authors' method.

9902. HÖBER, R., und G. ORZECHOWSKI. Über die Harnbildung in der Froschniere. XXI Mitteilung. Beobachtungen an den Cilien im Halsabschnitt der Harnkanälchen. *Pflüger's Arch. Ges. Physiol.* 226(1): 164-170. 1930.—In perfusion experiments on the frog's kidney, when the aorta is perfused with appropriate concentrations of a narcotic (such as phenyl-urethane) or of KCN, the authors have observed a cessation of urine formation which they attributed to an effect upon the secretory activity of the glomerulus. In their present article they consider the alternate possibility that this cessation of urine flow may be due to damage inflicted by their drugs upon the cilia located in the proximal tubule near to the glomeruli. They describe methods for the observation of the activity of these cilia under normal circumstances, and find that an apparently normal degree of activity (the observations are qualitative in nature) persists in these cilia after they have been exposed to concentrations of narcotics or KCN which were sufficient to arrest urine formation.—*K. A. Elsom.*

9903. HOLTON, SYLVIA G., and R. R. BENSLEY. The functions of the differentiated parts of the uriniferous tubule in the mammal. *Amer. Jour. Anat.* 47(2): 241-273. 1 pl. (col.) 1931.—Observations on the excretion of Fe and of indigocarmine in the rabbit at low blood pressures and in the dehydrated animal showed that secretion of these substances continues at levels of blood pressure at which glomerular filtration is impossible and that it is a function exclusively of the proximal convoluted tubule. The secretion so produced is small in amount and high in concentration. It flows along the tubule into the descending limb of Henle's loop, rarely, in long experiments, enters the ascending loop, and may even reach the distal convoluted tubule. The dehydration experiments show that the concentration of the urine by resorption of water occurs in the ascending limb of Henle's loop and in the distal convoluted tubule. In these experiments there is no evidence of further concentration in the ducts. The capsule of Bowman remained free from Fe or indigocarmine in all experiments, indicating that the excretion of these substances in the rabbit is, under the conditions of our experiment, an exclusively tubular function.—*Authors (courtesy Wistar Bibl. Serv.).*

9904. HUGHES, B., und T. PÉTERFI. Der Nachweis von Uroselektan im Glomerulus der Froschniere. *Zeitschr. Urol. Chir.* 31(3/4): 146-152. 2 fig. 1931.—Male frogs (number not stated) were injected with 2 cc. of 2.5-3% urethane solution, the abdominal skin incised, 0.5 cc. of 40% uroselectan injected into a vein, the point of injection washed with physiological saline, and the kidneys exposed. They should be of a reddish-brown color; if darker or anemic the glomeruli are more difficult to distinguish. The testes were excised, the bladder emptied, and a kidney elevated and padded with cotton soaked in physiological saline. The frog was placed under the microscope and sufficient fluid kept on the body so that the kidney was slightly submerged. Micropipettes filled with physiological saline, inserted into the glomeruli, took up any uroselectan. One half hr. after injection 0.003-0.006 mgm. I, corresponding to 0.0071-0.0142 mgm. uroselectan, was recovered; control punctures gave no I. (I was determined quantitatively within 0.003 mgm. limit of error.) By calculation the kidneys would excrete 28 mgm. in ½ hr. and the total amt. injected in 5 hrs.

9905. HUTTER, KARL, und MAX SGALITZER. Zur röntgenologischen Darstellung der Nieren und Harnwege durch intravenöse Injektion von Uroselektan. *Fortschr. Geb. Röntgenstrahlen* 41(6): 919-935. 23 fig. 1930.—Uroselectan is a pyridin derivative with 42% I in organic combination. Intravenously injected, it is excreted through the kidneys, about 95% of the I being eliminated with the urine in 6-8 hrs. if the kidneys function normally; the I is not split off in the organism. After using it in 110 cases, the authors pronounce it suitable for use in cases in which catheter pyelography is impracticable.

9906. IRVING, J. T. A note on the permeability of the kidney cell to glucose. *Guy's Hosp. Rept.* 80(3): 343-347. 3 fig. 1930.—While, during studies of the osmotic relationship of the rabbit's kidney, considerable increases in weight were easily obtained in hypotonic solution, a decrease in weight in hypertonic solution was much more difficult to observe; this suggests some renal mechanism for counteracting the effects of high osmotic pressures, which might be expected from the normal function of the kidney. When the effects of glucose solutions were investigated, this last fact was found to operate still more strongly. It was early seen that the cell membrane was impermeable to glucose, but satisfactory decreases in weight could not be observed even when strong solutions were used. The effects of glucose were therefore observed in 2 ways: (1) the inhibition of swelling in glucose solutions of increasing strengths; (2) the changes in weight obtained by placing kidney tissue first in a hypotonic solution and then in glucose solutions of varying concentrations. By the 1st method, kidney tissue was placed in a phosphate buffer 0.05 *M*, pH 8, and glucose added to bring to concentrations of the required amounts. The tissue in buffer alone swelled rapidly; that in 0.28 *M* (5%) and 0.56 *M* (10%) glucose swelled much more slowly. That in 0.83 *M* (15%) glucose did not change in weight, and the addition of more glucose to bring the concentration from 0.83 *M* to 1.11 *M* (20%) produced no further changes. By the 2nd method, 4 specimens were made up and incubated for 1½ hrs. without glucose. The increases in weight were approximately equal. Glucose in concentrations of 0.28 *M*, 0.56 *M*, 0.83 *M*, and 1.11 *M* was then added to the respective tubes, and the kidney tissue weighed at half-hourly intervals. All save the sample in 0.28 *M* glucose fell markedly in weight, the fall being in proportion to the strength of the glucose present. The kidney in its much-diluted condition was presumably isotonic with 0.28 *M* glucose. It is concluded that the cell membrane is not permeable to glucose. Probably the factor responsible for the degradation of glucose is situated on the cell surface.

9907. JORES, A. Perspiratio insensibilis. II. Über die Beziehungen zwischen renaler und extrarenaler Wasserausscheidung. *Zeitschr. Ges. Exp. Med.* 74(5/6): 757-768. 1930.—Water metabolism normally bears no relation to the water output of the skin. Under basal conditions there is no increased extrarenal water excretion in disturbances of water metabolism. On increased water administration a transitory increase was seen in 3 cases. A diminution of extrarenal excretion occurs in edema and in great water loss. Euphyllin produces an increased skin output of water, salyrgan does not; there are exceptions to both these statements. Fluctuations of weight loss are influenced by fluctuations in skin water output. Loss of water by the lungs is of no significance in water metabolism. Increased skin water output depends upon increased sweat gland activity. The insensible perspiration, in the strict sense, is not increased. It is concluded that the skin output of water is of no significance in water regulation. From a regulatory standpoint the extrarenal excretion becomes important; its extent is apparently dependent upon the water con-

dition of the organism.—*Author's summary (transl. by H. L. White).*

9908. KNOLL, W. Zur Frage der Eiweissausscheidung bei sportlicher Arbeit. *Arbeitsphysiologie* 3(5): 409-414. 1930.—The urines of a man during a period of 3½ mos. training in horseback riding were collected immediately after the periods of riding and examined for albumin and microscopically. Albumin was found at the beginning, disappeared after weeks of training and returned whenever the training was unusually severe due to learning new performances or when an untrained horse was being taught. The appearance of albumin was limited to the urines collected at the end of the riding periods; it was not found in subsequent urines. Formed elements and cylinders were never found. The type of albumin elimination is parallel to orthostatic albuminuria and has no connection with inflammatory processes in the kidneys.—*T. M. Carpenter.*

Physiol.* 272(2): 504-530. 1929.—The ratios of C to N and of "Vakat-O" to N were determined in a series of 13 rabbits, before and after administration of varying doses of P subcutaneously in oil. No definite effects were noted with small doses. Lethal doses caused a decrease in the ratios, attributable to increased N elimination. Sub-lethal toxic doses caused a lowering of the ratios, followed by a return to normal or higher accompanying recovery. The experiments are tabulated, with further data on sugar, albumin and chlorides in the urine; these are not elaborated in the text.—*B. S. Walker.*

9910. KUNO, YAS. The significance of sweating in man. *Lancet* 218(5565): 912-915. 1930.—Translation of a lecture given at the annual meeting of the Jap. Assoc. for the Adv. of Science. Sweating was induced by increase of room temp., by local heating, by mental stress (psychical sweating as opposed to physiological). Regional differences were determined by a method described in some detail. The conclusions are that the sweat glands function for:—regulation of body temp.; the facilitation of physical work; and the protection of the skin.

9911. KUO, K. W. On mental sweating at high atmospheric temperature, including a paradoxical phenomenon in sweating on the palm of the hand. [In Japanese, with English summary, pp. 33-34.] *Jour. Oriental Med.* 14(4): 1931.—Sweating was provoked in 6 young men by mental effort (arithmetic) and by increase in room temp. While under ordinary conditions mental exertion produced sweating on the palm and in the axilla, at high external temp. sweating due to mental effort became more profuse in the axilla but did not occur on the palm.

9912. LEVI, M., ed E. SAPEGNO. La perspiratio insensibilis dopo il bagno di mare. [Perspiratio insensibilis following sea baths.] *Boll. Soc. Ital. Biol. Sperim.* 5(3): 297-299. 1930.—The perspiratio was studied by means of special devices (absorbing capsules). In all cases a conspicuous increase of the perspiratio insensibilis was observed following the sea bath. Individual differences were recorded. The increase persisted usually more than 1 hour after the bath. The increase is not to be explained by a water imbibition by the keratin layers of the skin, it being observed also when a direct contact between skin and water was avoided.—*M. Comel.*

9918. MAC KAY, EATON M. Use of phenol red in the Addis test of renal function. *Proc. Soc. Exp. Biol. & Med.* 27(9): 1039-1041. 1930.—Preliminary paper.

9919. MAINZER, FRITZ, und ANNA JOFFE. Zur Analyse des Säurebasengleichgewichts im Harn. *Biochem. Zeitschr.* 203(1/6): 50-87. 1928.—Convalescents were kept on standardized diet and water intake, were given bicarbonate and NH_4Cl. The 24-hr. urines were analyzed for: pH, total N, total base, NH_3, Cl, phosphates, total CO_2 (after equilibration with an atmosphere of 40 mm. CO_2 pressure), titratable acidity (phenol red pH 7.4), organic acids. All analytical results are given in extensive tables. Simultaneous increase in the excretion of acid and ammonia does not necessarily indicate an

acidosis, but in many cases an alkali-sparing tendency, measurable by the equation

$$\frac{100\ (NH_3 + \text{titratable acidity} - \text{bicarbonate})}{\text{Total nitrogen}}$$

with quantities expressed in milliequivalents. Administration of NH_4Cl tends to increase the numerical value of this expression; bicarbonate ingestion gives it a low or negative value. The numerator of the above expression, divided by the total base, serves as an expression for the alkali-sparing effect. The use of these expressions in the interpretation of urinary acidity measurements is discussed in detail. The regulation of acid-base elimination independently of the excretion of solids, by means of variations in the excretion of NH_3 and CO_2, is demonstrated. The presence of unknown organic bases in the urine is suggested.—*B. S. Walker.*

9920. **MARSHALL, E. K. Jr. A comparison of the function of the glomerular and aglomerular kidney.** *Amer. Jour. Physiol.* 94(1): 1-10. 1930.—A comparison of certain functions of aglomerular as opposed to glomerular kidneys of fish has been made. The goosefish and toadfish have been studied as having aglomerular kidneys, while the sculpin, flounder, carp, and eel have served as representatives of marine and fresh water fish with glomerular kidneys. The composition of the urine of marine teleosts is found to be essentially the same in both types of fish. The threshold phenomena shown by the glomerular kidney are exhibited by the purely tubular kidney; chloride and phosphate may disappear from the urine under some conditions and under others may be present in large amounts. The aglomerular kidney differs from the glomerular one in showing a specificity in the elimination of foreign bodies. Thus, the aglomerular kidney eliminates phenol red, but fails to eliminate the highly diffusible ferrocyanide. Glycosuria is easily produced in fish with glomerular kidneys, but only a trace of glucose ever appears in the urine from an aglomerular kidney, even when the blood sugar is high and phlorhizin has been given.

9921. **MARX, HELLMUT. Diuresis by conditioned reflex.** *Amer. Jour. Physiol.* 96(2): 356-362. 1931.—In experiments on 4 dogs reflex diuresis was obtained as a result of psychic stimuli. Marx believes this to be: (1) evidence for the importance of cerebral mechanisms in the regulation of diuresis, and (2) provision of a method for the study of psychic mechanism whereby it is possible to obtain a quantitative measure of the effects produced.

9922. **MILONE, SEBASTIANO. Sul processo di ipertrofia compensatoria nel rene scapsulato. [On the process of compensatory hypertrophy in the decapsulated kidney.]** *Arch. Sci. Med.* 54(9): 639-651. 1 fig. 1930.—In the hypertrophy of the decapsulated kidney of albino rats two stages follow: a first (10 days after operation) during which the decapsulated kidney is heavier than the hypertrophied non decapsulated one. In a following stage the weight of the decapsulated kidney, although increasing, is less than that of the hypertrophied intact kidney. The compensatory hypertrophy is less pronounced in the decapsulated kidney following probably circulatory defects.—*M. Comel.*

Biol. Sperim.* 5(4): 582-584. 1930.—When kidney cortex was administered together with diuretics, a fall of the diuresis resulted.—*M. Comel.*

9924. **NIKOLAJEV, O. W. Über die Wirkung von K- und Ca-Ionen auf die Funktion der isolierten Speicheldrüse mit degenerierten Nerven.** *Pflüger's Arch. Ges. Physiol.* 226(6): 689-693. 1 fig. 1931.—Under local anesthesia the chorda tympani nerves and the periarterial sympathetic nerves to the submaxillary gland were sectioned in each of several dogs. After intervals of 6-30 days, the dogs were killed and the glands removed for the perfusion experiments. Increasing the Ca concentration of the perfusion fluid resulted in an increase in the rate of flow of saliva. An increase of K in the perfusion fluid had the opposite effect. An increase of either K or of Ca, however, produced vasoconstriction. These results are identical with those obtained under similar conditions with glands taken from animals in which the nerves had not been severed.—*M. H. Friedman.*

9925. **ORZECHOWSKI, GERHARD. Über die Harnbildung in der Froschniere. XX. Über den Mechanismus der Ausscheidung von Säurefarbstoffen.** *Pflüger's Arch. ges. Physiol.* 225(1): 104-117. 1930.—A large number of acid dyes have been studied to see whether, when brought to the second section of the tubule of the frog's kidney by way of the renal-portal vein, they can penetrate the walls of the tubules and then be excreted in high concentration. The results are as follows: 1. There is a group of dyes for which the wall of the tubule is impermeable, which are insoluble in Nirenstein's oil mixture and to which erythrocytes are impermeable. 2. The dyes of a 2nd group are soluble in Nirenstein's oil mixture, permeate blood corpuscles and are excreted by the tubule in concentrated form. 3. A 3rd group is insoluble in Nirenstein's mixture and in blood corpuscles but is excreted in concentrated form. Members of group (3) are excreted in higher concentration than are members of group (2).—*Author's summary.*

9926. **ÖSTBERG, OTTO. Der Citronensäuregehalt des Harns bei Acidose und Alkalose.** *Biochem. Zeitschr.* 226 (1/3): 162-163. 1930.—Östberg had previously found a daily average citric acid excretion of 0.23-1.85 gm. in 25 normal persons. He now finds in 200 normal persons a daily average of 0.2-1 gm.; in pathologic conditions (renal insufficiency, chronic uremia, diabetes, etc.) subnormal citric acid values, and an increase in citric acid after oral administration of $NaHCO_3$, even when all other factors were unchanged. Simultaneous determinations of NH_3 and citric acid in the urine show rise of one coinciding with fall of the other and vice versa. Hence Östberg concludes that citric acid is one factor, though a small one, in the regulation of the acid-base equilibrium of the body.

9927. **OTTOW, B. Das funktionelle Verhalten des vesikalen Ureterostiums nach vorausgegangener Nephrektomie oder tiefer Harnleiterdurchschneidung.** *Zentralbl. Gynäkol.* 55(11 a): 767-781. 1 fig. 1931.—Cystoscopic observations in 17 patients showed that if the residue of the ureter was not injured normal functional movements continued even for yrs. after the operation but at much greater intervals.

9928. **PACHUR, REINHOLD. Die Talgabsonderung auf der menschlichen Hautoberfläche.** *Arch. Dermatol. u. Syph.* 162(2): 253-259. 1930.—In 180 analyses on 40 patients it was found that in healthy persons a forehead area of 4 sq. cm. has a fat content of 0.4-0.48 mgm. This is higher during puberty, lower during old age. In most persons with eczema, acne vulgaris, and folliculitis the secretion of sebum is increased, 0.61-1.72 mgm. being found; in patients with pronouncedly dry seborrhea and acrodermatitis atrophicans it was reduced; psoriasis was not characteristic. When washed off, sebum is usually replaced in 5 min. If dissolved with petroleum ether or benzine it returns slowly. By estimation, the sebum content of the skin in healthy man is 1.6-1.8 gm.

9929. **PANDAZIS, GEORG. Zur Frage der Bakteriensymbiose bei Oligochäten.** *Zentralbl. Bakt. I Abt. Orig.* 120(7/8): 440-452. 5 fig. 1931.—In the nephridia of many oligochetes occurs a bacterium with stable morphological and biological features. The bacteria (always highly localized in a segment of the adult organ) infect the embryo, but have no pathogenic effect on the adult nor the embryo; the relation appears to be a symbiotic one. The celom fluid of the terrestrial oligochetes contains protein which enters the nephridia together with the urine and is split in the ampullae by proteolytic enzymes into albumoses and peptones through the action of the bacteria inhabiting this segment of the nephridia; probably this renders possible the resorption of the

protein from the wall cells of the ampulla and of the proximal part of the glandular canal. The nephridial fluid contains uric acid, purin bases, ammonia, and chlorides; the last are excreted by the proximal parts of the nephridial canal, while the N-containing metabolic waste matter is excreted in the distal parts of the segmental organ. Urea and sugar are not present in the urine. Reaction of the nephridium contents was acid.

9930. PRIBRAM, HUGO. Über das Harnadialysat. *Biochem. Zeitschr.* 211(4/6): 412-419. 1929.—Human urine was dialyzed against water or N/10 H_2SO_4. The non-dialyzable residue contains a water insoluble precipitate and a water soluble fraction. Treatment of the latter with alcohol-ether gives a precipitate which can be purified to an ash content of 11%. The adialysate gives some protein reactions, causes miosis and sleep in rabbits. The effective dose was about the equivalent of 27 cc. urine per kgm. of rabbit, but was variable. The adialysate from urine in 2 cases of Bright's disease had these biological effects; that from another case with N retention did not. The effect of the adialysate from 2 cases of diabetes mellitus was less than normal. The adialysate of urine is a product of protein metabolism and is eliminated from the blood by the kidney (vide Pribram and Herrnheiser, Biochem. Zeitschr., 111: 30, 1920). It will be interesting to study the quantity and biological effects of the adialysates of urine in all diseases characterized by disturbance of protein metabolism.—*H. Pribram.*

9931. PÜTTER, AUGUST. Die Sekretionsmechanismen der Niere. 235p. 17 fig. Walter de Gruyter: Berlin, 1929. Pr. 17.50 M.—This work, an extension of the author's "Dreidrusentheorie der Harnbereitung," presents experimental evidence that the kidney is an aggregation of secretory mechanisms of different types, each of which elaborated in definite ratio a specific product and its characteristic attendant substance (Schleppersubstanz). The mechanism acts as a gland in accordance with the law of "all or none"; the composition of the elementary secretion is independent of the secretion rate. Analyses of many urines of man, rabbit, cat, sheep, ox, elephant and frog were made both under normal conditions and in water, salt and urea diuresis and subjected to statistical analysis to determine the types of secretory mechanisms and their products. He concludes that the mechanism for the secretion of purine bodies together with, and in definite ratio to, a polysaccharide is present in all vertebrates. Water "glands," the output of which can be measured by the concomitant hippuric acid (40 mgm./100 cc. H_2O) and colloidal chondroitin sulfuric acid (40 mgm./100 cc. H_2O) are apparently located in Bowman's capsule. Mechanisms for the secretion of Na, K and NH_3 together with a S-free, N-containing substance, urea which is accompanied by a colloidal, protein-like substance, and Cl together with a colloidal substance apparently identical with Salkowski's complex N-containing carbohydrate, are identified. In addition to those substances elaborated by the secretory mechanisms, urine contains material present by virtue of the action of purely physical processes and not due to energy expenditure by the kidney. Some of the urine urea (73 mgm./100 cc.), Cl, Na and K are thus accounted for. Uric acid and Ca "flooding out" are not detectable; creatinine "flooding out" is noted only in the rabbit. Studies of night and day human urine show that the water and salt glands are less active in the elaboration of night urine. There is a discussion and criticism of Cushny's theory of urine secretion, a chapter on gland physiology and one on methods and data.—*E. Pomerene.*

9932. QUAGLIARIELLO, G., e E. TRIA. L'equilibrio acido-basico nei cani in seguito al taglio dei vaghi. [Acid-base equilibrium in dogs following vagotomy.] *Boll. Soc. Ital. Biol. Sperim.* 5(6): 1016-1019. 1930.—Vagotomy is not followed by marked alterations of the acid-base balance of blood, only a slight acidosis occurring, probably due to an increased blood CO_2 tension due to a diminished pulmonary ventilation. The bicarbonate content of blood diminished, as did the alkali reserve, the bicarbonate content of urine being on the contrary much increased. Ammonia is also much increased in urine of vagotomised dogs. A possible modifying action of vagotomy on the composition of urine is pointed out. —*M. Comel.*

9933. RABINOWITCH, I. M. The origin of urobilinogen: a clinical experiment. *Arch. Internal Med.* 46 (6): 1014-1017. 1930.—In a patient suffering acute abdominal pain excessive urobilinogen appeared in the urine while the blood bilirubin was normal. At operation a large ovarian cyst was found filled with sterile blood. That the mass of blood in the cyst was the source of the excessive urobilinogen appears obvious from the fact that in a specimen of urine obtained 12 hrs. after operation, i.e., after the removal of the mass of extravascular blood, the quantity of urobilinogen was normal. This appears to demonstrate that urobilinogen may not only be formed in the body outside the intestinal tract, but also in the absence of bacteria as reducing agents.

9934. RALESCU, C. GH. Consideratiuni asupra refluxului ureteral. [Considerations on the ureteral reflux.] *Rev. Med.-Chirurgicală din Iași.* 38(6): 539-553. 1927.—The bladder-kidney or bladder-ureteral reflux constitutes a syndrome determined by a free communication between the bladder and the superior urinary tract. This syndrome previously considered to be the result of various causes, congenital or acquired, presents always a fundamental character, physiological incompetence of the ureteral sphincter. As a result of numerous clinical observations, verified through cystoscopy, and some through radiography (cystography, pyelography), I consider this syndrome to appear frequently during vesical or renal affections, of widely various pathogeny. All the pathogenic causes, usually believed to determine it (mechanical, inflammatory, nervous), can be reduced to a single essential factor, microbic infection, which determines by the direct action of the microorganisms, or their toxins, the paresis of the ureteral sphincter.—*C. Gh. Ralescu.*

9935. REID, W. L. The effect of intravenous injections of distilled water on the kidney. *Amer. Jour. Physiol.* 90(1): 168-171. 10 fig. 1929.—Injection of 0.5-1 c.c. dist. H_2O per kgm. produced marked but brief decrease in renal volume. The norm was regained in 1 to 2 min. Bl. press. was not affected. The decrease in vol. was due to the osmotic effect of dist. H_2O. The action is specific for the kidney and the mechanism is peripheral for similar results were obtained on denervated kidneys. Dist. H_2O caused specific vasoconstriction of renal vessels due to periph. stim. Inj. of laked bl. made hypertonic with NaCl had the same effect as dist. H_2O. Cells and plasma of normal bl. were separated and treated with dist. H_2O and injected, after being made hypertonic with NaCl. Injection of plasma gave no decrease in vol. Injection of cells produced a marked decrease. R. concludes that decrease in volume is due to some substance produced by distilled H_2O injuring the erythrocytes and which causes specific vasoconstriction of renal vessels.—*M. R. Freeland.*

9936. RESNITSCHENKO, MICHAEL S. Die aktuelle Reaktion des Harns und deren Beziehung zur Ermüdung. *Biochem. Zeitschr.* 210(4/6): 393-402. 5 fig. 1929.—Healthy men 22-23 years old (3 strong and 2 weak) were obliged to (1) walk 15 km. with a 27-kgm. load in 3 hrs.; (2) walk 8 km. with the same load up a 7° incline; (3) creep on the earth with the same load for 10 min.; (4) proceed at 5 km. per hour (with same load) without rest until completely exhausted. Exhaustion was reached after 16.2-27 km. Blood cH, gaseous metabolism, state of the leucocytes, etc., were determined. After hard labor with heavy load the cH of the urine increased. In persons in good training the cH did not increase and sometimes diminished. The variation of the cH corresponded to the intensity of the work.—*H. Přibram.*

413. 6 fig. 1929.—A march of 10 km. with load increased the elimination of H-ions in the urine. In strong persons the elimination was first diminished and then increased. After short intense labor (running 500 and 700 m.) the H-ions in the urine increased. The variation of the H-ions in the urine corresponds to the character of the labor. The absolute quantity of the eliminated H-ions in the urine was dependent upon the degree of fatigue.—*H. Přibram.*

9938. RICHARDS, A. N., and ARTHUR M. WALKER. Quantitative studies of the glomerular elimination of phenol red and indigo carmine in frogs. *Jour. Biol. Chem.* 87(3): 479-498. 1930.—Following the subcutaneous injection of phenol red and indigo carmine into a frog, fluid was collected from a glomerular capsule and its dye content analyzed by placing it in a small glass capillary tube and comparing the visible color with that of standard dye solutions placed in capillaries of similar bore. The dye content of specimens of plasma taken during the course of a glomerular collection was similarly estimated. When the color is completely developed by preliminary alkalinization, and a proper background is used, it becomes easily possible, for example, to distinguish a solution containing 3 mgm. per 100 cc. from one containing 4 mgm. per 100 cc. by this method. 25 experiments were performed. When suitable precautions were observed (obstructing the proximal tubule with a blunt glass rod) to prevent contamination by tubular contents, the dye content of the glomerular fluid was found identical with that of an ultrafiltrate of the plasma from which it was derived; both glomerular fluid and ultrafiltrate containing less color than plasma by virtue of the adsorption of dye upon plasma proteins. The process of filtration was therefore held sufficient to explain the glomerular elimination of these dyes. In two subsequent papers of this series comparisons were made of the total molecular concentration (Barger's method) and electrical conductivity of glomerular fluid and plasma; in both instances these properties of glomerular fluid were also identical with those of an ultrafiltrate of plasma.—*A. M. Walker.*

9939. RIOCH, DAVID McK. Water diuresis. *Jour. Physiol.* 70(1): 45-52. 1930.—Large dogs (12-36 kgm.) in good condition were used, and their urine tested for albumin and casts. Blood samples (approximately 10 cc. each) were taken from the femoral artery or from the left heart. The urine was collected by catheterization, and the volume measured with an accuracy of 2%, care being taken to empty the bladder each time. One or more control experiments were run on each dog in exactly the same way as the experiments on diuresis, except that no fluid was given, and only 3 samples of blood were taken. Administration of isotonic saline solutions to 4 dogs perorally constantly gave a low delayed diuresis with slight concentration of the blood serum electrolytes, and considerable dilution of the total solids of the blood serum. Following administration of water perorally (10 experiments on 8 dogs), marked variations in reaction were found, especially in the degree of dilution of the total solids. The curve of diuresis, however, followed the changes of the electrolytes. There was a constant lag of 15-20 min. of the diuresis behind the changes of concentration of the electrolytes in the blood. The dilution of the electrolytic concentration of the blood was probably the responsible factor in instigating a water diuresis.

9940. ROST, F. Über Blasen- und Nierensteine im Tierversuch. *Arch. Klin. Chir.* 162(Kongressbericht): 701-708. 1930.—A discussion of methods, successful and unsuccessful, used by Rost and others to produce calculi in experimental animals.

9941. SALKIND, S. J., (with appendix by A. ANIKIN). Farbstoffausscheidung in den malpighischen Gefässen der Insektenlarven. *Zeitschr. Wiss. Biol. Abt. C., Zeitschr. Zellforsch. u. Mikrosk. Anat.* 10(1): 53-72. 11 fig. 1929.—*Chironomus* larvae were placed in solutions of basic dye stuffs (neutral red, toluidin-blue, and nile-blue sulphate) and acid dyes (trypan-blue, trypan-red, and indigo-carmin); the solutions were of .003%-.00075% in case of basic dyes, or .001%-.003% in case of acid dyes for 30-40 larvae. Larvae were removed from the solutions at times varying between 15 min. and 96 hrs., sectioned, and their malpighian tubules studied. In as short a time as 15 min. traces of neutral red could be found in the malpighian tubules. The intensity of the coloring was least at the distal end of the cells and greatest at the apical. At the end of 40 hrs. the cells were filled with fine colored granules except for a clear place in the middle of the cell. Taking up of dye by the malpighian cells did not appear to be a function of dye concentration after a certain threshold concentration of dye had been reached. Different dyes were taken up in different ways. Gentian violet appeared in the malpighian cells as odd shaped granules of considerable size, neutral red appeared as fine dots, toluidin-blue was generally inclosed in round vacuoles in which the dye was present on the edges. The granular inclusions of dye appeared to be not only dye, but also in part compounded from the cell proteins themselves. After the dye was taken into the cells lining the tubules it was first gathered up into vacuoles and then excreted into the canal lumen. The dyes in the canal were present in smaller particles than in the cells. Narcotized *Chironomus* larvae excreted dye granules in from 1 hr., 15 min. to 1 hr., 50 min.; unnarcotized animals in from 30-40 min. Low concentrations of chloretone increased the permeability of malpighian tubules to dye. This increase in permeability was reversible. Higher concentrations produced an irreversible change in permeability, followed by death. Mixtures of .2% and .3% chloretone with dyes were excreted normally. Mixtures of .4% and .6% were not excreted. *Corethra* larvae tolerated a greater concentration of dye than did *Chironomus*. Excretion of dyes was never observed in situ in the malpighian tubules of *Corethra*. Dyes were absorbed in the intestinal cells when injected. Malpighian tubules could be plasmotized. Experimental conditions similar to those of oliguria and polyuria could be produced in them. In the appendix A. ANIKIN defends his work on excretion of dyes in the rat kidney. He obtained marked tanning of the epithelial cells of 1 kidney, without any staining of the other. He also found no evidence of filtration of dye through the glomerulus.

9942. SATO, KAORU. Über den Wasser- und N-Haushalt der Gewebe nach Glukoseinfusion. II. Mitteilung. N-Haushalt der Gewebe nach Infusion hypertonischer Glukoselösung. *Tohoku Jour. Exp. Med.* 13(5/6): 553-567. 1929.—The intravenous injection of hypertonic solutions of glucose into male rabbits causes an excessive excretion of urea, parallel with an excess of N and P. The N is that of urea, ammonia, and creatinin. This condition was accompanied by the presence of a decreased amount of extractable N in the tissues without affecting the amount of their protein N. The leaching of extractable N not only concerns the nitrogenous products of metabolism but also in a higher degree those constituents precipitable by phosphotungstic acid. The increased excretion of P is also accompanied by a diminution of extractable P in the tissues.—*J. M. Johlin.*

9943. SATO, KUNIO. Further study on the real nature of vital staining. *Folia Anat. Japonica* 8(6): 391-400. 2 fig. 1930.—A further study to elucidate the real nature of vital staining gave the following results. If a rabbit is injected with KCl before vital staining, the epithelium of the renal tubules takes up more stain than does the epithelium of a normal rabbit. On the other hand, stain granules deposited in the epithelium readily escape when a vitally stained animal is subsequently injected with KCl. A reverse result follows treatment with $CaCl_2$. If trypan blue is injected with KCl, the animal excretes blue urine; red urine is discharged if the stain is injected with $CaCl_2$. The color of the excreted urine coincides with that of stain granules appearing in the epithelium after vital staining with trypan blue in combination with K or Ca. The author's interpretation of these results is that the renal

protein from the wall cells of the ampulla and of the proximal part of the glandular canal. The nephridial fluid contains uric acid, purin bases, ammonia, and chlorides; the last are excreted by the proximal parts of the nephridial canal, while the N-containing metabolic waste matter is excreted in the distal parts of the segmental organ. Urea and sugar are not present in the urine. Reaction of the nephridium contents was acid.

The urine was collected by catheterization, and the volume measured with an accuracy of 2%, care being taken to empty the bladder each time. One or more control experiments were run on each dog in exactly the same way as the experiments on diuresis, except that no fluid was given, and only 3 samples of blood were taken. Administration of isotonic saline solutions to 4 dogs perorally constantly gave a low delayed diuresis with slight concentration of the blood serum electrolytes, and considerable dilution of the total solids of the blood serum. Following administration of water perorally (10 experiments on 8 dogs), marked variations in reaction were found, especially in the degree of dilution of the total solids. The curve of diuresis, however, followed the changes of the electrolytes. There was a constant lag of 15-20 min. of the diuresis behind the changes of concentration of the electrolytes in the blood. The dilution of the electrolytic concentration of the blood was probably the responsible factor in instigating a water diuresis.

9940. ROST, F. Über Blasen- und Nierensteine im Tierversuch. *Arch. Klin. Chir.* 162(Kongressbericht): 701-708. 1930.—A discussion of methods, successful and unsuccessful, used by Rost and others to produce calculi in experimental animals.

9941. SALKIND, S. J., (with appendix by A. ANIKIN). Farbstoffausscheidung in den malpighischen Gefässen der Insektenlarven. *Zeitschr. Wiss. Biol. Abt. C., Zeitschr. Zellforsch. u. Mikrosk. Anat.* 10(1): 53-72. 11 fig. 1929.—*Chironomus* larvae were placed in solutions of basic dye stuffs (neutral red, toluidin-blue, and nile-blue sulphate) and acid dyes (trypan-blue, trypan-red, and indigo-carmin); the solutions were of .003%-.00075% in case of basic dyes, or .001%-.003% in case of acid dyes for 30-40 larvae. Larvae were removed from the solutions at times varying between 15 min. and 96 hrs., sectioned, and their malpighian tubules studied. In as short a time as 15 min. traces of neutral red could be found in the malpighian tubules. The intensity of the coloring was least at the distal end of the cells and greatest at the apical. At the end of 40 hrs. the cells were filled with fine colored granules except for a clear place in the middle of the cell. Taking up of dye by the malpighian cells did not appear to be a function of dye concentration after a certain threshold concentration of dye had been reached. Different dyes were taken up in different ways. Gentian violet appeared in the malpighian cells as odd shaped granules of considerable size, neutral red appeared as fine dots, toluidin-blue was generally inclosed in round vacuoles in which the dye was present on the edges. The granular inclusions of dye appeared to be not only dye, but also in part compounded from the cell proteins themselves. After the dye was taken into the cells lining the tubules it was first gathered up into vacuoles and then excreted into the canal lumen. The dyes in the canal were present in smaller particles than in the cells. Narcotized *Chironomus* larvae excreted dye granules in from 1 hr., 15 min. to 1 hr., 50 min.; unnarcotized animals in from 30-40 min. Low concentrations of chloretone increased the permeability of malpighian tubules to dye. This increase in permeability was reversible. Higher concentrations produced an irreversible change in permeability, followed by death. Mixtures of .2% and .3% chloretone with dyes were excreted normally. Mixtures of .4% and .6% were not excreted. *Corethra* larvae tolerated a greater concentration of dye than did *Chironomus*. Excretion of dyes was never observed in situ in the malpighian tubules of *Corethra*. Dyes were absorbed in the intestinal cells when injected. Malpighian tubules could be plasmotized. Experimental conditions similar to those of oliguria and polyuria could be produced in them. In the appendix A. ANIKIN defends his work on excretion of dyes in the rat kidney. He obtained marked tanning of the epithelial cells of 1 kidney, without any staining of the other. He also found no evidence of filtration of dye through the glomerulus.

9942. SATO, KAORU. Über den Wasser- und N-Haushalt der Gewebe nach Glukoseinfusion. II. Mitteilung. N-Haushalt der Gewebe nach Infusion hypertonischer Glukoselösung. *Tohoku Jour. Exp. Med.* 13(5/6): 553-567. 1929.—The intravenous injection of hypertonic solutions of glucose into male rabbits causes an excessive excretion of urea, parallel with an excess of N and P. The N is that of urea, ammonia, and creatinin. This condition was accompanied by the presence of a decreased amount of extractable N in the tissues without affecting the amount of their protein N. The leaching of extractable N not only concerns the nitrogenous products of metabolism but also in a higher degree those constituents precipitable by phosphotungstic acid. The increased excretion of P is also accompanied by a diminution of extractable P in the tissues.—*J. M. Johlin.*

9943. SATO, KUNIO. Further study on the real nature of vital staining. *Folia Anat. Japonica* 8(6): 391-400. 2 fig. 1930.—A further study to elucidate the real nature of vital staining gave the following results. If a rabbit is injected with KCl before vital staining, the epithelium of the renal tubules takes up more stain than does the epithelium of a normal rabbit. On the other hand, stain granules deposited in the epithelium readily escape when a vitally stained animal is subsequently injected with KCl. A reverse result follows treatment with $CaCl_2$. If trypan blue is injected with KCl, the animal excretes blue urine; red urine is discharged if the stain is injected with $CaCl_2$. The color of the excreted urine coincides with that of stain granules appearing in the epithelium after vital staining with trypan blue in combination with K or Ca. The author's interpretation of these results is that the renal

cells loosened by K allow the less diffusible blue substance in trypan blue to pass through the cell bodies as readily as the highly diffusible red one, so that both are discharged in a large quantity and the color of urine becomes blue. At the same time, much storage of stain takes place in the epithelium. Reverse results occur if the cells are condensed by Ca. The author maintains that the agglutinative deposition of the stain in the living cell depends upon the intracellular concentration of the stain molecules and, in turn, on the permeability of the cell.—*Author (courtesy Wistar Bibl. Serv.)*.

9944. SCHERSTÉN, BERTIL. Kommt Zitronensäure im Menschenschweiss vor? *Skand. Arch. Physiol.* 59 (3/4) : 92-97. 1 fig. 1930.—Ten attempts have been made to determine by Thunberg's method the concentration of citric acid in human sweat collected in warm dry air. The smallest concentration which can be determined by the method under the conditions imposed is 5 mgm. per liter. In no sweat has the citric acid content reached this value. The citric acid content of the sweat probably amounts to only 1 to 2 mgm. per liter. The action of NaCl upon the citricodehydrogenase was studied; in 0.1 molar NaCl solution the activity of the enzyme is reduced about 10%. Urea and uric acid do not affect the enzyme. The significant negative result is of special interest in view of the abundance of citric acid in human urine.—*Author's summary (transl. by H. L. White)*.

9945. SCHMIDT, CARL F., and J. M. HAYMAN, Jr. A note upon lymph formation in the dog's kidney and the effect of certain diuretics upon it. *Amer. Jour. Physiol.* 91 (1) : 157-160. 1929.—In 6 experiments on dogs with sulphate diuresis the results showed loss of renal fluid unaccounted for by the urine. In 9 experiments on dogs measurement of urine, blood and lymph flow from the left kidney (the other abdominal viscera having been removed or tied off) showed that diuretics uniformly increased lymph flow along with increase in urine and blood flow. Additional injection experiments with diffusible dye confirmed the conclusion that fluid can leave the blood within the kidney to enter lymphatics as well as ureter, and that escape through both channels is augmented by the same agents, i.e., by diuretics.

9946. SHINOBU, CHIKARA. On the reaction of the skin capillaries of the palm and the dorsal region of the hand to mental and thermal causes. [In Japanese, with English summary, p. 15.] *Jour. Oriental Med.* 14 (2) : 1931.—Experiments on 7 young men and 1 young woman showed that sweating due to mental stress is restricted to the palm of the hand, the sole of the feet, and the armpit, while an increase in the surrounding temp. provokes sweating over all the rest of the body surface, thus dividing the surface of the body into 2 areas. Mental arithmetic performed for 5-10 min. produced dilatation of the skin capillaries of the palm, but did not affect the capillaries of the back of the hand. Immersion of a foot or of one hand in cold water (4° C.) for 20-30 min. produced in the other limb initial hyperemia, followed by constriction (4-5 min. in the palm, about 30 min. in the dorsal region) and later dilatation, with gradual fall of temp. on both sides of the hand, interrupted in the palm by a transitory tendency to rise about 10 min. after beginning of cooling. Application of heat (hand or foot placed in water at 46° C. for 20-30 min.) produced dilatation of skin vessels of dorsum and palm, followed in the palm by constriction and congestion, temp. rising in proportion to dilatation, i.e., continuously during application of heat on the dorsum, but transitorily, with later fall, in the palm. Shinobu concludes that the reaction of the skin vessels to different causal agents varies in different parts of the body surface. Whenever a part of the skin is made to perspire, there is an arterial congestion. This is the case in the palm during mental stress, and in the dorsal region of the hand during the application of heat. Therefore, the above classification of the body surface with regard to its ability to perspire may probably be applied also to the reaction of the skin vessels.

9947. SMITH, HOMER W. (with the assistance of NICHOLAS FARINACCI and ANNE BREITWEISER). The absorption and excretion of water and salts by marine teleosts. *Amer. Jour. Physiol.* 93 (2) : 480-505. 1930.—It is shown that marine teleosts swallow relatively large quantities of sea water which subsequently undergoes absorption. Most of the ingested water, Na, K and Cl are absorbed from the intestine, leaving a residue rich in Mg and SO_4 and approximately isotonic with the blood. The salts of the urine consist primarily of Mg and SO_4, with only traces of K and small quantities of Na and Cl, the solution being isotonic or hypertonic to the blood. It is shown that the intestinal Mg and SO_4 come from ingested sea water, and that the urinary Mg and SO_4 come from alimentary absorption of these substances. Quantitative analysis of the composition of the ingested sea water, the intestinal residue and the urine lead to the following conclusions: 1) The osmotically dilute nature of the intestinal residue and urine elaborated from sea water shows that the marine fish is doing osmotic work at some point other than in the kidneys and gastro-intestinal tract. 2) The fact that Mg and SO_4 occur in greater concentrations in both the intestinal residue and the urine than in the ingested sea water from which these fluids are derived shows that part of the water absorbed from the alimentary tract is excreted by some route other than the kidneys. The fact that relatively more Na, K and Cl are absorbed from the alimentary tract than Mg and SO_4, while less Na, K and Cl are excreted in the urine than Mg and SO_4 shows that a large part of the absorbed NaCl and KCl is being excreted by some route other than the kidneys. By considering these 3 processes as identified with a single process, it is inferred that the marine fish excretes by some extrarenal route a solution of NaCl and KCl which is hypertonic to the ingested sea water and thus leaves part of the absorbed water free for the formation of the osmotically dilute urine and intestinal residue. The extrarenal excretion of water is demonstrated in *Anguilla* and *Myoxocephalus* by the addition of phenol red to sea water and the quantitative, simultaneous determination of the quantity of water ingested and the quantity of urine excreted in a given time. The extrarenal excretion of salts is demonstrated in the catadromous eel, *Anguilla*, when kept in fresh water. The greater part of the NaCl and KCl absorbed from the alimentary tract is excreted by the extrarenal route, while essentially all the Ca, Mg, SO_4 and PO_4 are excreted by the kidneys. In the absence of other salts, SO_4 takes Na into the urine with it, and Mg and Ca take Cl. Reasons are given for believing that the extrarenal excretion of salts and water and the extrarenal performance of osmotic work are attributable to the gills. The water for the formation of urine in fresh water fish is not absorbed from the stomach or intestine, but probably from the oral membranes. The water cycle in marine fish is of such a nature as to reduce the quantity of water excreted as urine to a small fraction of that excreted in fresh water fish. It is suggested that this relative anuria is the principal causative factor in an evident tendency for the glomeruli to disappear in the kidneys of strictly marine teleosts.—*Author's summary*.

9948. SNAPPER, I., en A. GRÜNBAUM. Melkzuuruitscheiding in de urine en in het zweet bij verschillende soorten sport. [Lactic acid excretion in urine and sweat during various sports.] *Nederlandsch Tijdschr. Geneesk.* 73 (11) : 1358-1365. 1929.—During heavy sports (football, rowing, running) lactic acid, formed in the muscles, is chiefly excreted with the sweat. During a football match (duration 2¾ hrs.) amounts of 1-2 gm. lactic acid are excreted through the skin. Runners attain a steady state in about 9 min. Swimmers and waterpolo players did not attain the steady state within 15-20 min. Albuminuria is rare at the end of the match, except after swimming in which case it is frequent. Glycosuria after a match is rare.—*J. W. Langelaan*.

9952. STEFFANUTTI, PIETRO. Der Verlauf der Entmischung von Farbstoffgemischen durch die gesunde und die vergiftete Niere. *Pflüger's Arch. Ges. Physiol.* 226(1): 148-163. 1930.—Diffusible dyes are excreted by the perfused frog's kidney, either by the glomeruli or by the tubular epithelium; in the latter case they are concentrated, in the former they are not (Höber). In intact frogs and rabbits the author finds essentially the same differences: Phenol Red (a "tubule dye") was excreted more rapidly and in much higher concentration than Cyanol (a "glomerular dye") following intravenous injection of a mixture of the two in equal concentration. Mixtures of other "tubule" and "glomerular" dyes behaved similarly, excepting lipid-soluble "tubule" stains (Orange R, Neutral Red), which, while concentrated by the perfused frog kidney, did not appear at all in the urine of the intact frog and were excreted only in traces by the intact rabbit; this discrepancy is attributed to taking up of such substances by other tissues. When two "glomerular" dyes were injected (Acid Fuchsin and Cyanol) both were excreted in approximately equal concentration. Parallel experiments on frogs and rabbits poisoned with uranium nitrate showed that "tubule" dyes are excreted more slowly and in lower concentration than in normals, while lipid-soluble "tubule" dyes or mixtures of "glomerular" dyes show no differences from the normal. The functional capacity of the renal tubules is therefore manifested in more rapid excretion and higher concentration of "tubule" dye than of "glomerular" dye, when both are injected simultaneously.—*C. F. Schmidt.*

9953. STEPPUHN, O., und A. TIMOFEJEWA, (unter Mitarbeit von N. NAUMOWA). Neue Vorstellungen in der Ketonkörperfrage. Bedeutung lokaler Säuerungsherde für den intracellulären Proteinumsatz. *Zeitschr. Ges. Exp. Med.* 74(3/4): 467-481. 1930.—The appearance of local centers of acidification on protein particles (surface of contact between protein and plasma) must have a decisive significance for the initiation of proteinolysis by pepsinase (kathepsin). This is demonstrated in experiments on a model. The ketonic compounds which are formed automatically in glycogen depletion in the liver are certainly not to be considered as intermediate stages of a fat-carbohydrate metamorphosis for it is shown by direct experiments that addition of fatty acid never results in increase of glycogen. The substitution of lost glycogen by protein-carbohydrate metamorphosis is a physiological process and the formation of ketonic compounds is to be interpreted as a process physiological in its quality and pathological only when excessive. This metamorphosis goes on in the liver which is an accumulator for protein. The protein-carbohydrate metamorphosis which necessarily accompanies glycogen depletion may perhaps be caused by accumulation of "fermentcapital"; i.e., amount of enzyme plus specific activators (zoökinase). But the appearance of local centers of acidification as affording conditions for the action of pepsinases may be of importance. At the very moment of protein-carbohydrate metamorphosis we notice the appearance of sometimes enormous amounts of acids (β-oxy-butyric acid and acetoacetic acid). The origin of these acids in the liver under determined conditions of glycogen decrease is not comparable to any other production of acids. The contraction of muscle is caused, in spite of probable appearance of other acids, only at the expense of the lactacidogenic acid; in the same way perhaps the protein-carbohydrate metamorphosis is incited specifically by the ketonic acids under certain determined conditions. We formulate the probable scheme as follows: a) Glycogen decrease of the liver (from any cause). b) Immigration of fat from the periphery into the liver and formation of ketonic compounds. c) Flaring up of local centers of acidification at certain reserve protein particles. d) Increase of proteinolysis by enzymes acting around acid centers. e_1) Formation of carbohydrate from protein debris to replace lost glycogen. e_2) Emigration of the ketonic compounds to places of excretion.—*Authors' summary (transl. by J. F. Wiedemann).*

9954. TALBERT, G. A., A. K. SAIKI, R. C. CARPENTER, J. BERGMEYER, H. STAFF, C. BORMAN, and D. FREEMAN. Simultaneous study of the constituents of the sweat, urine and blood, also gastric acidity and other manifestations resulting from sweating. VIII. Blood changes. *Amer. Jour. Physiol.* 97(3): 426-431. 1931.—Profuse sweating was provoked by moist heat (temp. 40-42 C.) generated by electric current, the subject being seated, 20-50 min. at a time, in the sweat cabinet with the head only protruding and arms and torso completely enclosed in a rather thick rubber dam jacket belted around the waist. The 54 subjects reported 3 times a wk., at 6:30, 8 and 10 o'clock respectively. There was a fairly good correlation between rise in body temp. and increase in blood concentration; in only 36 out of 320 experiments was there no concentration. Under the given conditions there was a fairly uniform decrease in CO_2 combining power (160 out of 212 experiments) and rise in blood pH (110 out of 134 observations). Further evidence is offered that the rise of body temp. provokes greater ventilation and thereby increases the blood pH.

9955. TANNENBERG, JOS., und WINTER. Experimentelle Nierenuntersuchungen. I. Beobachtungen bei der Injektion von Trypanblau in den Glomerulusraum der lebenden Froschniere. *Frankfurter Zeitschr. Path.* 37(1/2): 1-17. 6 fig. 1929.—Trypan blue, 1% in Ringer's solution was injected into the glomerular capsules of frogs and the tubular epithelium studied 5 min. to 48 hrs. later. Forty eight hrs. after injection dye granules were seen in the tubule cells; earlier there were no granules but a diffuse coloring. Intermittence of glomerular capillary flow was observed.—*H. L. White.*

9956. TRUC, EUGÈNE. Contribution à l'étude de l'histophysiologie du rein. Elimination rénale des substances fluorescentes; épreuve fluoroscopique.—Appareil de Golgi de la cellule rénale; ses variations morphologiques dans la sécrétion rénale.—Élimination rénale des sels de plomb et de fer. *Arch. Malad. Rein. et Org. Genito-Urin.* 5(1): 1-48. 1 pl. (col.), 2 fig. 1930.—In normal human subjects 30-50 yrs. old (number not stated) the elimination of trypaflavin, determined by fluoroscopy, began 5-15 min. after intravenous injection, and continued, decreasing after 30-60 min., up to 48 hrs. In cats and guinea pigs (number not stated) injected with neutral red and killed 3 hrs. later, the kidney treated by Cajal's method was found secreting and the Golgi apparatus of the renal cell appeared granular. In other animals, examined when the kidney

was not secreting, the Golgi apparatus was granular. Hence there appears to be a morphologic variation in the renal Golgi apparatus according to the secretory phase of the kidney. Salts of Fe and Pb, administered to cats and guinea pigs, were found to occupy first a basal, then an apical situation in the cells of the convoluted tubules, finally filtering by dialysis into the lumina of the tubules.

9957. **VOIT, K. Beitrag zur quantitativen Eiweissbestimmung im Harn.** *Zeitschr. Ges. Exp. Med.* 72(5/6): 760-761. 1930.—Scherer's method and determination of coagulable N gave closely corresponding values in 2 cases of nephrosis and 1 of glomerulonephritis.

9958. **WALKER, ARTHUR M. Comparisons of total molecular concentration of glomerular urine and blood plasma from the frog and from Necturus.** *Jour. Biol. Chem.* 87(3): 499-522. 1930.—A study has been made of Barger's microscopic method of estimating molecular weights as used by White in comparing the total molecular concentrations of glomerular urine and blood plasma from *Necturus*. White's belief in its usefulness for this purpose was confirmed. In 25 comparisons of glomerular urine and blood plasma from frogs, the total molecular concentrations of the 2 fluids were found to be the same within the limits of permissible experimental error. In 8 experiments in which differences in concentration were greater than could be ascribed to permissible error, the differences were not consistently in one direction and in all but one could be attributed to identified flaws in experimental technique. In 6 experiments, phenol red was injected and its concentration in the 2 fluids also determined; in 7 others electrical conductivity was also measured. The results of these additional estimations agreed well in showing that glomerular urine has the composition of a protein-free filtrate from plasma. Twelve similar comparisons were made of the total molecular concentrations of glomerular urine and blood plasma from *Necturus maculosus*. The results were like those on the frog. In 4 instances they were supported by the concordant results of electrical conductivity measurements. The outcome of these experiments conflicts with that of 12 experiments made by White on *Necturus* which seemed to show that the glomerular urine is more concentrated than the plasma from which it is derived. Our experience suggests that it easy to underestimate the importance of dangers of evaporation.—*Author's summary.*

9959. **WATZADSE, GIORGY. Über die Harnbildung in der Froschniere. XIV. Über die Bedeutung der Aminosäuren für die Nierentätigkeit.** *Pflüger's Arch. Ges. Physiol.* 219(5/6): 694-705. 1928.—Absence of glycine from perfusion fluids decreases the arterial blood flow through the frog kidney, and may stop it entirely. This causes cessation of production of urine, which often fails to start again after renal circulation has been reestablished by addition of glycine to the perfusate. Glomerular function appears to be affected by lack of glycine directly as well as indirectly through the circulation. This is inexplicable on a filtration theory. The chloride-content of urine is increased by glycine in the perfusate. Glycine also influences the vessels of the frog intestine and liver, but has no effect on the vessels of the limbs. Other amino-acids and some amido compounds have an effect similar to glycine.—*W. R. Fearon.*

9960. **WIGGLESWORTH, V. B. Excretion of uric acid.** *Nature [London]* 128(3220): 116. 1931.—A study of the excretory system of the blood-sucking bug *Rhodnius prolixus* leads to the formulation of a theory that the upper parts of the 4 Malpighian tubes secrete a solution of acid urates from the blood into the lumen, and that in the lower parts water and base are reabsorbed, leading to a precipitation of the insoluble uric acid. Thus there is continuous circulation of water and of base.

9961. **WINTON, F. R. The influence of increase of ureter pressure on the isolated mammalian kidney.** *Jour. Physiol.* 71(4): 381-390. 1931.—The influence of increase of ureter pressure has been studied by comparing its effects on 1 kidney with those of a decrease in arterial pressure of a 2nd kidney, in experiments in which both kidneys were isolated and perfused with defibrinated blood from the same heart-lung circulation, and in which both secreted urine of approximately the same composition and at the same rate under the same initial conditions. When the rates of urine flow are thus reduced equally in the 2 kidneys, the changes in the urea and chloride contents of the urines are also equal. No regular change in the blood flow through the isolated kidney was detected as a result of increase of the ureter pressure up to a value (e.g., 20 mm. Hg) which almost abolished the flow of urine. It is inferred that an increase of ureter pressure increases the pressure of the fluid in Bowman's capsule, and so retards the rate of production of the intra-capsular fluid. No direct influence on the activity of the tubular epithelium has been detected. The applications of this hypothesis to the measurement of changes in the glomerular pressure, the permeability of the glomerular membrane, and the effective osmotic pressure of the plasma proteins, are indicated.—*Author's summary.*

tozoa by drugs. *Nature [London]* 127(3210): 708. 1931.—Experiments on the chemical stimulation of the sperm of the guinea pig indicate marked stimulation by strychnine hydrochloride at 1/64% with equal stimulation by brucine hydrochloride at 1/16%. Chloral hydrate at 1/16% had far less stimulating value.

9965. **BECKER, R. B., and P. C. McGILLIARD.** Measuring the influence of hormone and mechanical stimulation by means of a non-fecund lactation. *Jour. Dairy Sci.* 12(5): 372-379. 2 fig. 1930.—Comparing lactation curves of 3 normal and 1 non-fecund lactation by a Holstein-Friesian cow, and from literature review, it was concluded that maximum daily milk yield was attained later in lactation, rate of decline in milk flow was less rapid, and persistency of production was not affected in non-fecund milk production. When induced by mechanical stimulation alone, maximum daily milk yield was 20-30% of that observed in lactations following normal reproduction.—*R. B. Becker.*

9966. **BENAZZI, MARIO.** Contributo alla istofisiologia dell'utero di mammiferi con particolare riguardo alla conoscenza delle cellule pigmentate. [Histophysiology of the mammalian uterus, particularly the pigmented cells.] *Arch. Ital. Anat. e Embriol.* 28(2): 163-210. 1930.—Benazzi had previously called attention to peculiar accumulations of interstitial cells rich in a yellowish pigment in the uterine connective tissue of mice, especially in the mesometrial region. This study is on the origin of these pigmented cells and the relation of the phenomenon to the pigment reported by others as formed in connection with estrus. Benazzi found these pigmented cells in ♀ mice at all stages of the sexual cycle, in bilaterally castrated ♀♀ and in ♀♀ which had ceased to present estrus. In the virgin ♀♀ of 2 litters of laboratory bred mice, killed and examined at various stages of the sexual cycle, however, the yellowish cells were found only in insignificant numbers; nor were any accumulations of yellow cells found in 2 primiparous mice killed during gestation, or in a primiparous mouse killed 24 hrs. after delivery. In 5 mice killed 3½ to 50 days after delivery pigmented cells and extracellular pigment were found. The formation of pigment is therefore ascribed to the lysis of blood cells from postpartum hemorrhages; the frequency of the occurrence, to the long persistence of the pigment. Thus, pigment found in a gravid uterus is explained by a previous parturition. The fact that the yellow pigment was not found in any quantity during estrus is accounted for by the infrequence of uterine bleeding in the mouse during heat. In guinea pigs, dogs and cats pigmented cells were not found regularly.

9967. **BICKEL, L.** Über die experimentelle Beeinflussung des Endothelsymptoms bei Frauen. *Zentralbl. Gynäkol.* 55(14): 1250-1257. 1931.—Rumpel-Leede's phenomenon has been found to occur during the last premenstrual days, the climacterium, and in ovarian dysfunction. Using 3 min. congestion at 20 mm. Hg above the diastolic pressure, the effect of drugs was tested on 174 women, results on 148 being reported. Using ovarian hormones (120 experiments "Unden," Hogival, "Progynon") doses of 100, 200, and 300 mouse units were given on 3 successive days perorally (superior to parenteral) and the test read on the 4th. Blood points up to 5 were considered negative, 5-15 weakly positive, 15-30 positive, 30-100 double positive, 100-200 triple positive, 200 and more 4-positive; only when positives had been present could the hormone be said to have suppressed it. Of 60 patients in the climacterium 8 showed no decrease, 28 a distinct decrease and 24 disappearance of the reaction. In 24 with anomalies of flow, 600 mouse units had no effect in 6, reduced the reaction in 3, and suppressed it in 15. In 13 patients, gynecologically healthy, 9 were unaffected; in 3 the reaction was decreased, and in 1 erased (carcinoma of the vagina with pronounced acro-asphyxia). Cases have been observed where a pronounced reaction disappeared spontaneously after a few days. Thyroxine produced no change in 6 of 9 cases, in 1 the endothelial permeability was made normal. After large doses of bromural for 3 days the reaction was erased in 6, reduced in 4. In 9 women the reaction was erased in 1, reduced in the others by 2 gm. cholesterol in 40-60 gm. oil on each of 3 days. Oil alone reduced it in 2 women, did not affect it in 2 others. In 4 cases 6 gm. cholesterol in 60 gm. oil was given and the reaction tested at the end of 4 hrs.; in 3 patients it had disappeared, in 1 been reduced. It would appear that the sexual hormone acts by way of the blood cholesterol.

9968. **BISSONNETTE, THOMAS HUME.** Studies on the sexual cycle in birds. IV. Experimental modification of the sexual cycle in males of the European starling (Sturnus vulgaris) by changes in the daily period of illumination and of muscular work. *Jour. Exp. Zool.* 58(1): 281-319. 3 pl. 1930.—In male starlings between December and May prolonging daily light rations increased the spermatogenic activity in testes, unless at complete spermatogenesis, whether this condition had resulted from previous experimental treatment or naturally without it. Shortening light rations caused regression in testes not already at minimal activity. Relative, not absolute, light ration at any time appears to condition the direction of reaction of germ cells. Results suggest that testes may be maintained at stages of partial regression by constant daily light and exercise rations for at least one month. Experimentally induced germ-cell changes resemble natural ones, except in time and speed of reaction. Prolonging "work" rations failed to cause progressive germ-cell changes, but increased intertubular pigment and caused an initial lag of light-induced changes followed by faster reaction, whether progressive or regressive. As in nature, interstitial cells were most numerous and typical during regression and early progression of germ cells, and, like fibroblasts, changed to connective-tissue-type cells during advanced germ-cell activity with its tension and pressure. No "fat-laden," "luteal," or "glandular" type interstitials were observed, nor evidences of interstitial secretory activity. Results suggest possible control, or modification at will, of male sexual cycles by controlled daily light periods or manipulation with electric-light bulbs emitting little or no ultraviolet.—*Author (courtesy Wistar Bibl. Serv.).*

9969. **BOKELMANN, O., und W. SCHERINGER.** Beitrag zur Kenntnis der Schilddrüsenfunktion und des Jodstoffwechsels in der Gestation. *Arch. Gynäkol.* 143(3): 512-536. 1931.—It was found in 19 blood I determinations on 43 women, as well as in continuous determinations in several women, in all periods of pregnancy, partus, and the puerperium that the I begins to rise in the 2nd-3rd mo., rises abruptly to the 7th mo., remains at that level until the 9th when it decreases slightly, is little affected by partus, decreases gradually during the puerperium, but in the course of several wks. does not reach the level of normal, nonpregnant women. No uniform relations were found between the I concentration of the blood and the basal metabolic rate, or carbohydrate assimilation.

9970. **BROWKIN.** Dr. Manoiloffs Reaktion zur Feststellung der Schwangerschaft (am klinischen Material). *Arch. Gynäkol.* 143(3): 688-692. 1931.—After 159 preliminary determinations, the author made more than 500 observations: 210 in normal pregnancy (1-10 mo.), 5 in hyperemesis gravidarum, 27 in the puerperium, 59 in nonpregnant subjects, 7 in children, 31 in men, 5 in the climacteric, 22 in gynecological diseases, and 16 in abortion. During pregnancy the positives were 90%, only 33 of 45 being positive before the 12th wk., however; the toxicoses were positive. During the 1st 14 days of the puerperium the reaction was positive, thereafter negative. The reaction was positive in 10 nonpregnant women and 5 children, negative in the others and in men. In the cases of abortion the reaction was positive twice, in gynecological diseases, 7 times.

9971. **CANDELA, NICOLÒ.** Acetonuria e peptonuria in ostetricia. [Acetonuria and peptonuria in obstetrics.] *Rass. Ostetr. e Ginecol.* 39(10): 598-620; (11): 667-683. 1930.—The urines of 50 women were examined. The

acetone bodies were: in 10 cases of normal pregnancy (later months) 19.6-32.7 mgm. %, av. 26.05 mgm. % (peptone never present); in 10 cases of physiologic puerperium, 38.5-57 mgm. %, av. 49.11 mgm. % (peptone present in 4 cases); in 10 cases of abortion, 38.3-60.4 mgm. %, av. 49.41 mgm. % (peptone in 4 cases); in 10 cases of retained placenta, 41.8-61.5 mgm. %, av. 50.41 mgm. % (peptone in 4 cases); in 10 cases of dead fetus, 46.3-71.3 mgm. %, av. 59.74 mgm. % (peptone in 7 cases). Simultaneous occurrence of acetonuria and peptonuria does not indicate, in Candela's opinion, a causal connection between the two. Rather, both phenomena are due to a single cause, the passage into the maternal circulation of products of the decomposition of fetal tissues.

9972. CLAUBERG, CARL. Experimentelle Untersuchungen zur Frage eines Mäusetestes für das Hormon des Corpus luteum. *Zentralbl. Gynäkol.* 19: 1154-1164. 1930.—Studies were made by the author of the state of the uterine and vaginal mucous membrane of the mouse immediately following oestrus. He demonstrated the existence of a special corpus luteum phase which reaches its peak 5 days after fertilization. This phase of the cycle is characterized by the absence of leucocytes in the vaginal mucous membrane and can only be demonstrated by careful histological studies. The vaginal smear method does not suffice. This phase can be called forth by the corpus luteum hormone (prepared according to the method of Corner and W. M. Allen). Castrated mice were brought into heat by means of injections of follicular fluid hormone. Six days after the appearance of the cornified epithelial cells (oestrus) the uterus and vagina atrophied if injections were discontinued. If the injections were continued the typical proliferation took place. Clauberg injected corpus luteum hormone into a series of mice immediately after the appearance of oestrus. Six days later uterus and vagina showed early gravid changes. These studies in more than 100 mice present further evidence of a second sex hormone which the author calls "luteohormone." The changes produced by luteohormone cannot be obtained with injections of follicular fluid hormone. Prolonged injections of follicular fluid hormone resulted in a pathological proliferation analogous to the disease entity known as "glandular hyperplasia" in the human. This pathological proliferation is fundamentally different from the pre-gravid and gravid transformation resulting from injections of luteohormone. The most suitable test animal for demonstrating the presence of luteohormone is the rabbit, since it has the most easily recognizable and striking corpus luteum phase.—*C. Clauberg (transl. by H. C. Mack).*

9973. DIERKS, KLAAS. Über die Verwendbarkeit der Manoiloffschen Schwangerschaftsreaktion. [Manoiloff's pregnancy reaction.] *Monatsschr. Geburtsh. u. Gynäkol.* 87(3): 285-293. 1931.

9974. DOUGLASS, MARION. Corpus luteum of pregnancy; persistence of pregnancy after excision of the corpus luteum in the early weeks. *Surg., Gynecol. and Obstetr.* 52(1): 52-55. 4 fig. 1931.—Removal of a corpus luteum during tubal sterilization failed to interrupt the course of a previously unsuspected pregnancy which terminated by spontaneous abortion 4 mos. later (about 5 mos. pregnancy), showing that human pregnancy, once its duration exceeds about 4-6 wks., is independent of the hormone supplied by the corpus luteum of pregnancy.

9975. FAUVET, EGON. Über das weisse Blutbild im Wochenbett unter besonderer Berücksichtigung der Lymphozyten. [The white blood cells, particularly lymphocytes, in the puerperium.] *Zeitschr. Geburtsh. u. Gynäkol.* 99(1): 58-71. 1930.—Samples of blood from 10 normal patients, 1 taken 30-45 min. and 7 between 18-168 hrs. postpartum, showed a leukocytosis beginning with acidosis directly after delivery. There is a predominance of polynuclears, usually showing a pronounced shift to the left; lymphocytes and eosinophils are greatly decreased. This polynucleosis decreases in the following days and the eosinophils reappear. By the 4th day the neutrophils and lymphocytes reach normal. At the same time there is a parallel fall in the alkaline reaction of the blood. From the 5th day the reaction is normal and there is a pronounced lymphocytosis for some days, caused by involutionary processes in the uterus which, in the sense of inflammation, make increased demands on the mesenchyme and therefore on the lymphocytic elements of the peripheral blood.

9976. FREY, SIGURD. Experimenteller Beitrag zur Entstehung der akuten und chronischen Entzündungen des Nebenhodens und Hodens. *Deutsche Zeitschr. Chir.* 218(1/6): 333-365. 8 fig. 1929.—Experimental production of movements of the seminal vesicles of the rabbit by electrical and pharmacologic stimuli in 22 series of rabbits (no. not stated) and by electric stimulation in 2 men indicated that movements of the seminal vesicles are not responsible for inflammations of the epididymis and testicle. Where no local uropoietic cause is demonstrable, Frey believes that hematogenous infection produces epididymitis. Anatomic considerations forbid ascribing urethral orchitis to infection through the epididymes; Frey believes the lymphatics to be the only possible channels of infection.

9977. GENTHER, IDA T. Irradiation of the ovaries of guinea-pigs and its effect on the oestrous cycle. *Amer. Jour. Anat.* 48(1): 99-137. 2 pl. 1931.—Long exposures with filtered x-rays and 40% of the cases of short exposures with unfiltered x-rays produced degeneration of both large and small follicles and their egg cells, usually without ovulation and without formation of a typical corpus luteum, but with hypertrophy of the theca-interna cells to form interstitial gland. Primordial follicles continued to mature partially or completely, but without any regularity; subsequently they underwent degeneration. Oestrous cycles continued, but were irregular in length; often the oestrous period was greatly prolonged. A large follicle (not necessarily mature) was present whenever oestrus had occurred. In the absence of corpus-luteum action, the cycle depended on the maturation of the follicles only—therefore their irregularity and frequent prolongation of oestrus. The genital tract and mammary gland showed typical oestrous changes; when oestrus was prolonged, the activity seemed abnormally intense. In 45% of the cases of short exposures with unfiltered x-rays, connective-tissue atresia of all the follicles occurred, except of some primordial ones. Uninjured primordial follicles developed subsequently to small follicles, which degenerated as soon as formed; thus no medium-sized or large follicles were ever present. Oestrous cycles were absent and the entire genital tract was in a continuous resting conditions.—*Author (courtesy Wistar Bibl. Serv.).*

9978. GIERHAKE, E., und H. NASSE. Über das Vorkommen von Arginase in menschlichen Hoden und Ovarien. (Ein Beitrag zur Frage nach den Beziehungen zwischen intermediärem Arginin-Stoffwechsel und Geschlechtsfunktion.) *Arch. Gynäkol.* 143(3): 592-597. 1931. Organ pap from 12 testes and 6 ovaries was added to 2% arginin solution at 37°. The testes showed much more active digestion (mean 28.9-29.46%) than the ovaries (mean 5.25-5.69%). The authors conclude that high arginin metabolism is a specific characteristic of the ♂ and apparently predominantly related to the genital function. Of 7 ♂♂ (newly born-3½ mo.) only 2 showed arginin metabolism; none of 4 ♀♀ (newly born-14 mo.) showed any. Thus the intermediate arginin metabolism of children differs from adults. Creatinine in the urine seems to show a similar dependence on sexual glands: abundant in children and eunuchs, absent in healthy adult men.

9979. HARTMAN, CARL G., and JOSEPHINE BALL. On the almost instantaneous transport of spermatozoa through the cervix and the uterus in the rat. *Proc. Soc. Exp. Biol. & Med.* 28(3): 312-314. 1930.—Preliminary paper.

9980. HARTMANN, H. Experimenteller Beitrag zur Frage der Placentarpermeabilität. (Übergang von Farb-

stoffen vom Fetus zum Muttertier.) *Zeitschr. Ges. Exp. Med.* 74 (5/6) : 709-712. 1930.—Dyes which are excreted by the kidneys were injected, after laparotomy of 9 pregnant guinea-pigs and 5 pregnant rabbits, through the uterine wall into the fetuses. The wound incision was closed and the excretion of dye by the mother observed, or, if none appeared, the animal was killed and the bladder and kidneys examined. Indigocarmin in 0.4% solution (used in 3 guinea-pigs) and "Patentblau" in 1:100 (1 guinea-pig) and 1:500 (1 guinea-pig), but not in 1:1000 (1 guinea-pig) passed from fetus to mother; cyanol (2 rabbits, 3 guinea-pigs) and trypan blue (4 rabbits) did not pass.

9981. HILL, H. GARDINER, and J. FOREST SMITH. The relation of fatness to sterility. *Jour. Obstet. and Gynaecol. Brit. Emp.* 37 (2) : 256-271. 1930.—The 198 cases of obesity in married women fall into 3 main groups: (1) those with a family tendency to obesity, i.e., hereditary or constitutional obesity, who are either fat from birth (28%) or who develop the condition in early life especially about the time of puberty (18.7%); (2) those who become fat in later life at times other than childbirth (21.6%); (3) those in whom obesity dates from childbirth (30.9%). In the 1st group primary sterility was rare, but when found was associated with amenorrhea. It is not shown by statistics, however, to be especially common in the constitutionally fat. In a certain proportion of these constitutional cases in later life there was a tendency to develop secondary sterility with hyperthyroidism. In the 2nd group sterility was common, especially among patients who became obese immediately after marriage. In the majority there was amenorrhea or mild hypothyroidism with regular menstruation throughout. In the 3rd group subsequent sterility was rare. This appears to be a form of simple obesity seldom associated with amenorrhea or hypothyroidism. Hence obesity developing subsequent to pregnancy is not liable to be associated with absent or diminished fertility. Obesity per se is not a cause of sterility. When the 2 conditions occur together, sterility is usually the result of amenorrhea, or occasionally of hypothyroidism.

9982. HOCHLOFF, A. W. Zur Kolloidchemie der Vernix caseosa. *Zentralbl. Gynäkol.* 55 (14) : 1281-1285. 1931.—Vernix caseosa (V.C.) (10%, 20%, and 30%) was mixed with 3% gelatine solution (3% gelatine as control) and the diffusion of $N/10$ and $N/5$ H_2SO_4, $N/25$ and $N/10$ HNO_3, $N/10$ CH_3COOH, $N/10$, $N/20$ and $N/50$ NaOH, $N/10$, $N/20$ and $N/50$ KOH, 5% and 10% $CuSO_4$, 0.1 and 0.5% methylene blue and 1% novocaine in mm. using Congo-red, neutral red or, with 1 novocaine test, Lugol's solution as indicators. V.C. delayed diffusion markedly and in proportion to its concentration. Small blocks of 10% gelatine and solidified gelatine and V.C. (10, 20, 30%) were dried; when immersed in distilled water, $N/100$ HCl, or $N/100$ NaOH the action was greater on pure gelatine; acid and alkali had the same type of action. The V.C. is a natural colloid protection against abnormal drying or swelling of the skin.

9983. HOFFMANN, FRIEDRICH, und KARL JULIUS ANSELMINO. Über den Milchsäureumsatz in der Schwangerschaft und seine Beziehungen zum Kohlehydratstoffwechsel, zur Leber- und Schilddrüsenfunktion und zum Kreislauf. II. Über die Ursachen der vermehrten Milchsäurebildung im Schwangeren-Muskel. *Arch. Gynaekol.* 142 (2) : 310-323. 2 fig. 1930.—Muscle in pregnancy doing moderate (measured) work gives off considerably more lactic acid to the blood than muscle in non-pregnant cases under the same conditions. Two main causes of increased lactic acid production may be (1) deficient O consumption (2) change of regulating mechanism of carbohydrate metabolism. Determinations on 3 pregnant and 3 non-pregnant women eliminated the first, but similar measurements of anaerobic lactic acid production in muscles of 10 pregnant and 10 non-pregnant rats gave an indeterminate result, as the increase lay within the limits of experimental error. A series of physiological and clinical investigations lead to the conclusion that the demonstrated increase of lactic acid production in pregnancy muscle is to be ascribed to increased thyroid activity. The conclusion rests on facts that thyroxin increases lactic acid production, and that heightened thyroid action is certainly found in pregnancy, and further the work- and resting-lactic acid values in exophthalmic goitre completely correspond to those of pregnancy. The question of increased carbohydrate consumption as a cause of greater lactic acid production is left open.—*W. P. Kennedy.*

9984. KNIBBS, GEORGE H. Proof of the laws of twinbirths. *Jour. & Proc. Roy. Soc. New South Wales.* 61: 347-353. 1927 (1928).—From a study of data taken from the Bureau of Census of the Australian Commonwealth, formulae have been developed which give separately the numbers of uniovular and diovular twins. The results show that, in 3 out of every 1000 maternity cases, regardless of the age of the mother, twins are produced by the division of a single fertilized ovum; and that the frequency with which 2 ova are effectively fertilized increases linearly with age until about 37, and then decreases. Over the entire child-bearing period, the uniovular cases for each year of age equal the sum of the cases of 2 ♂♂ and 2 ♀♀, less the cases of ♂ and ♀. —*H. C. McPhee.*

9985. LASOWSKY, J. M. Beobachtungen über die Wirkung hoher Temperatur der Aussenwelt auf die Hoden von weissen Mäusen. (Experimentell-morphologische Untersuchung.) *Virchow's Arch. Path. Anat. u. Physiol.* 280 (1) : 311-324. 10 fig. 1931.—Entire litters of white mice were subjected to continuous temp. of 32-35° C. (absolute humidity 25.6-30.9, relative—72-74%); usual diet. After 2-45 days the animals were killed or 1 testis removed. The action of high temp. was found to be dependent upon the season. In fall and in winter it caused pronounced degeneration of seminal epithelium; usually spermatocytes and spermatids degenerated first, appearing to be most sensitive to high temp., while they were more resistant to x-rays than the spermatogonia. Degeneration of seminal epithelium was followed by regeneration, which usually ended with a complete restoration of the testes to normal. High temp. had no influence upon regeneration. In spring and in summer the testes, in spite of continuous heating of the animals, remained either entirely unchanged or (in isolated cases only), there was a great degeneration of spermatocytes and spermatids. Different sensitivity of testes to high temp. in various seasons seemed to be due to specific peculiarities of these organs.

9987. LEWIN, H. Die Lage des Oxydations-quotienten des Harns bei der Menstruation. *Arch. Gynaekol.* 140 (1) : 191-201. 5 fig. 1930.—Coincident with menstruation there is N retention, and a less complete oxidation of foodstuffs, as measured by the O necessary to oxidize the organic matter in the urine to completion. This oxygen is called Vakat-O. Normally the ratio Vakat-O/N equals 0.9. During menstruation it rises to 1.6.—*F. Bernheim.*

9988. MALFATTI, J., und J. BURTSCHER. Die Beeinflussung der Alkalireserve des Blutes durch Schwangerschaft, Geburt und Wochenbett, sowie ihr Verhalten beim Neugeborenen. *Arch. Gynäkol.* 143 (2) : 272-309. 1930.—Investigations were made on 14 women with samples of blood obtained during pregnancy, 1-2 times during the 1st stage, directly after the birth of the child, the day following partus, the day after the appearance of lactation, and on the 6-8th day, before the patient left her bed. Samples were obtained from the infants directly after birth from the umbilical vein, thereafter from the sagittal sinus. In healthy pregnant women the recognized acidotic state of the alkali reserve (A.R.) was found.. During partus there is a further decrease of the A.R., more distinct in primiparae than in multiparae; during the 1st 3-4 days of the puerperium there is a rise of the A.R. which, however, does not reach normal. Lactation influences the CO_2 combining power

of the blood, decreasing the A.R. if the blood is sampled more than 12 hrs. after the appearance of lactation; thereafter the non-pregnant normal is not attained even by the 12th-21st day of the puerperium. In 1 case of hyperemesis of pregnancy and in 1 of nephropathia gravidarum with high albumin in the urine, the A.R. was lower than for healthy pregnant women. Septic conditions produce an especially low A.R. The A.R. of the newly born in the blood of the umbilical vein is lower than that of the mother at the same time, and during the 1st 21 days the infant shows an acidosis which is usually more pronounced than the maternal. No typical influence on the A.R. in the newly born could be found by the physiological loss of weight or the transition from colostrum to milk.

9989. MANZI, LUIGI. Azione diretta del liquido follicolare sulla motilità tubarica. [Direct action of follicular fluid on the tubal motility.] *Boll. Soc. Ital. Biol. Sperim.* 5(6): 1020-1025. 2 fig. 1930.—Follicular fluids acted on human tube preparations increasing the height of movements, which become more regular. In some experiments addition of follicular fluid to the Ringer's solution was followed by the occurrence of a hitherto absent rhythmical motility of the tubes.—*M. Comel.*

9990. MAURIZIO, EUGENIO. Azione dell'urina di gravida sugli organi genitali degli animali da laboratorio. [Action of the urine of pregnancy on the genital organs of laboratory animals.] *Rass. Ostetr. e Ginecol.* 39 (10): 591-595. 1930.—Guinea pigs were substituted for mice with satisfactory results in the Aschheim-Zondek and Brouha-Hinglais-Simonnet tests for pregnancy (the latter in 18 cases).

9991. MILLS, C. A., and F. A. SENIOR. Does climate affect the human conception rate? *Arch. Internal Med.* 46(6): 921-929. 1930.—Birth statistics of cities, states and countries were obtained. The numbers of births in each month for a number of yrs. were taken, the mean for each month obtained, and the 12 months equalized to a 31 day basis for comparison. Where the population changed more than 1% a yr. during the period covered by the statistics used, correction was made. The corrected monthly births were then transposed to conception times by counting back 9 months and 10 days, and these "conceptions resulting in live births" were plotted. The graphs show that human fertility, as indicated by the conception rate, is highest in any given population at about 65 F., and that it is reduced during the low temp. of the northern winter and by mean summer temp. above 70° F. The summer depression is roughly proportional to the rise in the mean temp. above 70 F. These changes in conception rate are not dependent on changes in the marriage rate or sexual activity of the population, and must therefore represent actual variation in human fertility.

9992. MINAMIKAWA, K. Experimental investigation of the effect of the nervous system on the function of the genital organs. Relation between sympathectomy and parasympathetic poison, and pregnancy. *Japanese Jour. Obstetr. & Gynecol.* 13(4): 433-436. 1930.—Periarterial sympathectomy was performed on the right hypogastric artery in non-pregnant ♀ rabbits (number not stated), pregnancy was induced, and in 27 or 28 days the uteri were removed and the fetuses on each side weighed and compared. No difference was found between the number, development and mortality of the fetuses on the sympathectomized and those on the normal side.

9994. NICOTRA, ANTONINO. Ricerche istologiche sulla mucosa uterina dopo la castrazione radiologica. (Nota preventiva.) [Histologic study of the uterine mucosa after x-ray sterilization.] *Arch. Radiol.* 6(1): 268-282. 1 fig. 1930.—Nicotra calls attention to the fact that the 1, 2 or 3 menstruations which may follow roentgen sterilization are precisely the same in number as the menstruations which may follow surgical oöphorectomy or occur during the 1st 3 mos. of pregnancy; they also correspond to the number of ova brought to maturity at once by the human ♀. Nicotra believes that by simultaneous irradiation of the ovaries and hypophysis in 4 cases and of the ovaries, hypophysis, thyroid and mammary glands (followed by 1 menstruation in 2 cases and by 2 menstruations in the 3 others) he has excluded the possibility that the post-operative menstruation may be due to a vicarious action of some of the parasexual organs. Nicotra offers the hypothesis that the death of the non-fecundated ovum is due to the hormone of the corpus luteum, which permits the maturation of new graafian follicles. When the ovary has been removed or its function suspended by irradiation, there are no longer corpora lutea and no possibility of the maturation of new follicles, and hence no agent destructive of ova. This theory would attribute the menstrual periods after operation, irradiation or fecundation to the ova last liberated, each of which, presumably, would have lived long enough, in the absence of corpora lutea, to produce a menstruation.

9995. PEARSON, MARGARET, and KARL PEARSON. On the relation of the duration of pregnancy to size of litter and other characters in bitches. *Biometrika* 22 (3/4): 309-323. 1931.—In Pomeranians, Pekinese and crosses between them, the mean duration of pregnancy is about 60 days, and the standard deviation about 3 days. The correlation of size of litter with duration of pregnancy is $-.45 \pm .05$; with order of pregnancy, $-.05 \pm .05$; with age, $-.17 \pm .06$. In the first case, size of litter is probably the causal factor and hastens the end of gestation. The correlation of duration with order of pregnancy is $+.18 \pm .06$; the regression is non-linear, the correlation ratio of duration on order being .38. The correlation of age with order of pregnancy is $+.80 \pm .02$; with duration, $+.15 \pm .06$. None of the factors considered explains the variation in duration. "Can it be that this duration is individual and possibly an inherited character? If so it would be of evolutionary importance."—*J. R. Miner.*

9996. PINCUS, GREGORY. The transplantation of mouse ovaries into the rat. *Anat. Rec.* 49(1): 97-101. 1931.—Twenty out of 40 spayed rats receiving transplants of mouse ovaries gave evidence of ovarian function as judged by vaginal smears and the occurrence of copulation. Oestral smears were observed from 1 mo. to 2½ mos. after transplantation. In several instances ovarian tissue present was probably derived from unexcised ovarian fragments, but in other cases the functional tissue was undoubtedly derived from the transplanted mouse ovaries. A litter of rats was produced by a female with a "regenerated" ovary. No rat-mouse hybrids were obtained.—*Author (courtesy Wistar Bibl. Serv.).*

9997. PORCHER, CH., et L. MAYNARD. La graisse du sang et la graisse du lait pendant la lactation. *Lait* 10: 601-613, 765-782. 1930.—A study is reported of the total fatty acids and unsaponifiable matter in the blood plasma of dry and milking cows. These constituents exhibit only small variations from day to day and at different hrs. in the same day. While the values for fatty acids and unsaponifiable matter vary for different individuals, the ratio between them tends to remain const. There is a parallel increase in both these lipids following parturition. Variations of 100% and more frequently occur in the percentage of fat in the milk obtained in consecutive milkings. Despite these large variations the blood lipids studied rarely vary more than 20% and the average variation is much smaller. No correlation is evident between the percentage of fat in the milk and the level of blood lipids at the time the milk is being secreted.—*L. A. Maynard.*

9998. SCHMERLING, S. Die Schwangerschaftsdauer beim Menschen und das Gesetz ihrer individuellen Veränderlichkeit. *Arch. Frauenk.* 16(4): 314-321. 1931.—Investigations of the duration of pregnancy in 931 wives showed an average period of 277.3 ± 0.4 days. The individual duration varied according to Quetelet's law of individual variation of biological characteristics. The greater the deviation from the average in the duration of individual pregnancies, the more infrequent the cases

deviations of 6 wks. and more being extremely rare (0.3%).

10000. WITTENBECK, FRANZ. Ovulationstermin und Konzeptionsfähigkeit bei der Frau. *Arch. Gynaekol.* 142(2): 446-473. 11 fig. 1930.—Knaus has no exact and reliable observations on the human to support his theory of the limited conception period in woman, but he has been forced to devise hypotheses based upon findings in animals. Nor do his observations on time of ovulation controvert the practical lesson that cohabitations at all times of the cycle can result in conceptions. Therefore, one can not place any dependence on his statement that there is a physiological sterility before the 11th and after the 17th day of the cycle. His investigations and observations show that in many cases an alteration in the function of the uterine musculature follows the cyclic changes of the ovary; his conclusions, however, go too far. Deductions made from the results gained by his method can under certain circumstances lead to serious confusion, because the uterus in its functional relationships is, according to my observations, not dependent upon the ovary alone. Of course, if we take into consideration the condition of the follicle described by R. Meyer as a special one, for which, however, the case published by Stieve furnishes a very plausible explanation, still, it has not been demonstrated that the condition of the uterine musculature (in the sense of the corpus luteum effect) is a proof of a closely preceding follicle rupture, because a corpus luteum can form without rupture of the follicle. On the other hand the rupture of the follicle can really occur much earlier. On these grounds, neither the location of the ovum nor the time of ovulation can be recognized with absolute certainty from experimental deduction.—*Author's summary (transl. by G. L. Kelly).*

Ital.* 40(8): 227-230. 1929.—*A. salina* has one eye to the metanauplius stage and is positively phototropic; with complete development of the visual apparatus it becomes negatively phototropic. Its phototaxis varies with the conditions of intensity of light, with adaptation to solar light or to darkness or to colored light, with temp. and the chemical composition of marine water.—*I. Bellisai (transl. by R. A. Muttkowski).*

10004. BETHE, A., und A. SALMONSON. Beziehungen zwischen Bewegungsfrequenz und Grösse des Ausbreitungsgebietes der Erregungen. (Versuche an Würmern und Myriapoden.) *Pflüger's Arch. Ges. Physiol.* 226(6): 749-760. 6 fig. 1931.—A cinematographic method was adapted for measuring the rate of movement in worms particularly of the myriapod *Julus,* in which the movements of the feet were investigated. The waves started in the hind end of the animal whether the whole animal or the front end of one cut in half was investigated. The rate of transmission of the waves and their rhythm were both increased by the sectioning of the animal. The results are discussed in relation to the size of the animal as affecting the rhythm of its movements and the conclusion is reached that rhythmical movements progress more rapidly the smaller the area in which the stimulation spreads.—*H. C. Bazett.*

10005. BODENHEIMER, F. S., und H. Z. KLEIN. Über die Temperatur-abhängigkeiten von Insekten. II. Die Abhängigkeit der Aktivität bei der Ernteameise Messor semirufus E. André von Temperatur und anderen Faktoren. *Zeitschr. Wiss. Biol. Abt. C. Zeitschr. Vergleich. Physiol.* 11(3): 345-385. 17 fig. 1930.—The general biology of the harvest ant, *Messor semirufus,* in Palestine is briefly described. Its activity is strongly bound with temp. and annually has 2 maxima, in April and December; and 2 minima, in January-February and August. From November to March, activity is stopped by cooler temp. and in summer and autumn by warmer temp. The optimum for the worker lies between 17-19° C. Temp. of 24° C. and above are tolerated only a short time. In winter the greatest number of individuals are active during the noon hours; in spring, during the evening; in summer, during the entire night; and in autumn, during the first half of the night. The preferred temp. for the different varieties was found to be between 18.4-20.3° C. Within each month the average velocity of running per second at different temp. formed an equilateral hyperbola. These hyperbolas are different in separate seasons, probably modified by physiological changes in the ants. No relation of activity to rain, dew, moonlight and wind could be established.—*H. Klein (transl. by D. Ludwig).*

10006. BUDDENBROCK, W. von. Untersuchungen über den Schattenreflex. *Zeitschr. Wiss. Biol. Abt. C, Zeitschr. Vergleich. Physiol.* 13(1): 164-213. 20 fig. 1930.—*Balanus* reacted only to darkening, *Hydroides* also to illumination and to the movement of the observer. *Branchiomma* and *Arca* did not react to darkening although they showed the shadow reflex on movement. The reaction time of *Balanus,* which the animal spent in its shell after darkening, depended on temp., on the intensity and duration of the shadow, and on the size of the illuminated surface. It was independent of the condition of adaptation. The minimal duration of the shadow which was necessary to initiate the reaction was less, the greater the intensity of light and the intensity of the shadow. The sensitivity with which *Balanus* responded to the shadow stimulus depended, whether or not the state of adaptation remained the same, upon the number of stimulated light sensory cells, and on the duration of exposure to the shadow; it was independent of temp. *Balanus* follows Weber's law with the limitation of von Puetter and Hecht. The sensitivity was greatest in moderate intensity, much less with very strong and very weak light. The shadow stimulus to which *Balanus* responds can be summated in various ways, 1st with other shadow stimuli, 2nd with mechanical stimuli. Subminimal shadow stimuli can be made effective by summation with other stimuli. The adaptation from dark to bright follows other laws than hitherto supposed. The sensitivity first sank to a minimum, and then increased gradually to the final value. After long

darkening *Balanus* and *Hydroides* were insensitive for a time to all light stimuli. This period was the greater in *Balanus* the smaller the final light and the smaller the original light. *Balanus* soon ceased to respond to rapidly succeeding shadow stimuli. This failure to respond appeared sooner the smaller the stimulus. *Balanus* reacts to all types of light visible to man and to ultraviolet.—*Author's summary (transl.)*.

10007. CHALKLEY, H. W. On the relation between the resistance to heat and the mechanism of death in Paramecium. *Physiol. Zool.* 3(4): 425-440. 1930.—Paramecia were exposed in saline solutions of different pH and inorganic salt balance to a temp of 40° C. The resistance of the organisms to this temp. is a function of both the pH and the saline constituents of the surrounding media. When resistance is expressed as a function of pH, the relation is bimodal with maxima in the alkaline and acid ranges and a minimum at neutrality. The positions and magnitude of the maxima and the magnitude of the minimum depend on the salt balance of the medium. Under these conditions, the mechanism of death varies (from cell coagulation to cell dissolution), probably as a result of changes in the cell membrane and rate of water intake which result from the changes in both pH and inorganic salt balance, superimposed upon changes of purely thermal origin.—*Author (courtesy Wistar Bibl. Serv.)*.

Sci.* 36: 365-366. 1929 (1930).—25 specimens were bisected near the middle of the body. The anterior halves survived in the majority of the cases, while all the posterior halves eventually died.—*F. A. Stromsten.*

10010. GALTSOFF, PAUL S. The rôle of chemical stimulation in the spawning reactions of Ostrea virginica and Ostrea gigas. *Proc. Nation. Acad. Sci.* 16(9): 555-559. 1 fig. 1930.—The discharge of eggs or sperm of the oyster is stimulated by the presence in the water of sexual products of the opposite sex. In the ♀ oyster the latent period varies from 6 to 38 min. and is independent of the concentration of sperm. The spawning reaction of the ♀ is followed by a refractory period lasting 2-5 days. In the ♂ the latent period varies from 5 to 12 sec.; the reaction is not followed by a refractory period. The active principle of sperm suspension does not pass through the collodion membrane, and is destroyed by heating for 15 min. at 55° C. The active principle of egg suspension is soluble in the sea water and withstands boiling for 10 min. The chemical stimulation is influenced by the temp., which determines the lowest limit (20° for *O. virginica*) below which the ♀♀ fail to spawn, and supplies initial stimulus for the spawning of the ♂.—*P. S. Galtsoff.*

10011. HAYES, FREDERICK RONALD. The physiological response of Paramaecium to sea-water. *Zeitschr. Wiss. Biol. Abt. C, Zeitschr. Vergleich. Physiol.* 13(1): 214-222. 1930.—Cultures of *P. caudatum* were made in various media, most satisfactory being 0.025% beef extract and turnips. All were made up in fresh water and salinities of 0.2, 0.4 and 0.6% secured by adding sea water; additional sea water was added up to 1.6% but paramecia did not thrive above 1.0%. Tests were made in bacteria-free pond-, or pond and salt water; O was expressed either as O consumption per unit time (microscopic count) or consumption per unit N per unit time (micro-Kjeldahl determinations on 3 cc. suspension). The animals reacted to changes in salinity in at least 4 ways: alteration in body shape, change in volume, variation in the proportion of water, and deviation from normal rate of respiration. The rate of O consumption decreased with increasing salinity to the point of isotonicity, after which respiration increased; the curve was thus U shaped.

10012. HOWELL, W. H. Humidity and comfort. *Science* 73(1895): 453-455. 1 fig. 1931.—The paper gives the results of observations made upon the sense of comfort of a class of 40-45 persons in the School of Hygiene and Public Health of the Johns Hopkins University during the fall and winter of the session of 1930-1931. The class met once weekly for an hr. in a lecture room with a capacity of 16000 cu. ft. which was controlled by an air conditioning apparatus. The temp. of the room was kept constant at 70° F., but the humidity was varied at different times between a low of 15-20% and a high of 55-60%. Votes of the class were recorded at each meeting on a designated scale of comfort. The main result was that for winter conditions when the dry bulb was kept at 70° F., and adequate renewal of air was provided, the great majority of the group (91-97%) found the conditions comfortable (comfortable or comfortably warm or comfortably cool) irrespective of the humidity within the ranges designated.—*W. H. Howell.*

10013. KAMADA, TAKEO. Control of galvanotropism in Paramecium. *Jour. Fac. Sci. Imp. Univ. Tokyo, Zool.* 2(2): 123-139. 1929.—The anodal galvanotropism of *Paramecium* may be induced by regulating the galvanic stimulation and by changing the kind and concentration of electrolytes of the surrounding medium. Cations may be divided into 2 groups according to their mode of bringing about the anodal galvanotropism: Ca and Sr belong to one group and Li, Na, K, Rb, Cs, NH_4, H, Ba, Mg, and Al to the other. In general anions do not seem to modify the property of the cations above described.—*Author's summary.*

10014. LÉPINEY, J. de. Note préliminaire sur le rôle de la vision ocellaire dans le comportement des chenilles de Lymantria dispar L. *Bull. Soc. Zool. France* 53: 479-490. 2 fig. 1928.—The attraction of caterpillars of *L. dispar* to forest trees is the result of visual impressions alone, to the exclusion of all other sensory reactions. By substituting for trees various silhouettes the forms and shadows of which could be varied, caterpillars were found to be attracted from a distance by relatively tall and straight forms, and not by objects that are broad and only slightly elevated. The extreme limits of the apparent dimensions within which attraction is produced are in the neighborhood of: height 9°, width 3°. Dark silhouettes are most attractive; very light ones either do not attract at all or repel, while those not too bright but lighter than the background may also attract.—*J. de Lépiney (transl. by D. L. Collins)*.

10015. MAIN, ROLLAND J. Stereotropism and geotropism of the salamander, Triturus torosus. *Pysiol. Zool.* 4(3): 409-422. 5 fig. 1931.—A positively stereotropic reflex, produced by rubbing the belly of a labyrinthectomized salamander, is inhibited in the normal animal by the presence of the labyrinths; whereas an inhibition of the normal leg-clasping reflex may be produced by stimulation of tactile sense organs other than those involved in the reflex. The normal animal, when placed on its back, orients itself through a stereotyped righting reflex in which the head is bent backward, rather than lifted, as is generally the case. This reflex is abolished by bilateral labyrinthectomy, to be replaced by a response to differential stereotropic stimuli. Responses to rotation are very similar to those of other animals, except for an absence of head and eye nystagmus. Unilateral labyrinthectomy produces tilting, dragging

of the feet of the injured side, and rolling movements if strongly stimulated when swimming. Animals lacking both vestibules no longer orient the head, show disturbances in walking, and are completely unoriented when swimming, although soon righting upon reaching the bottom. The eyes seem to be of no importance in equilibrium. Repetitive mechanical stimulation of the spinal column produces a strong opisthotonus, which may be explained as due to direct stimulation of the linearly arranged motor neurones of the cord. The elicitation of this opisthotonic reflex is greatly facilitated by the injection of strychnin.—*Author (courtesy Wistar Bibl. Serv.).*

10017. PANTIN, C. F. A. On the physiology of amoeboid movement. V. Anaerobic movement. VI. The action of oxygen. VII. The action of anaesthetics. *Proc. Roy. Soc.* [*London*] *B* 105(740): 538-555. 6 fig.; 555-565. 2 fig.; 565-579. 5 fig. 1930.—Studies are reported on a marine *Limax* amoeba.—V. In the absence of O, gradually diminishing amoeboid movement continues for 6-12 hrs. The amoeba then abruptly passes into an inactive condition. Anaerobic activity is accompanied by morphological changes. There is a definite relation between the velocity of movement and the duration of anaerobiosis. Movement continues not only when O is completely absent, but when the external medium has considerable reducing power. Evidence is given that the energy of amoeboid movement is supplied by an anaerobic process, which allows movement to continue in the absence of O. O is required for recovery after anaerobiosis; this recovery occurs even after 48 hrs., but anaerobic inhibition of movement is ultimately irreversible. It is concluded that the anaerobic processes of amoeboid movement are normally accompanied by an oxidative recovery process. Recovery is progressively delayed as the period of anaerobiosis is increased beyond about 6 hrs. Delayed recovery occurs in 2 stages; the amoeba is at first inactive, and then suddenly resumes activity, as in immediate recovery. The delay is caused by increase in duration of the inactive phase. Delay in recovery increases long after all activity in the anaerobic amoeba has ceased, and is therefore not altogether dependent on activity. The delay may be related to the accumulation of an "oxygen debt."—VI. With a limited O supply, movement diminishes and ceases. But its duration is greatly prolonged when a trace of O is present as compared with the duration under complete anaerobiosis. The duration of movement increases with the O pressure. After complete anaerobiosis, O is required for recovery; prolonged activity in the presence of a trace of O may therefore be due to this recovery process operating to a limited extent. After a given duration of O deficiency, the greater the deficiency has been, the greater is the time required for the amoeba to recover in aerated sea-water. The efficiency of the recovery process during O deficiency therefore diminishes with the O pressure. As an O pressure of 30-40 mm. Hg is approached the activity of the amoebae increases. Above this critical pressure movement is maintained as long as in controls in aerated sea-water.—VII. The morphological changes and other effects of cyanide in amoebae (below 10^{-1} *M*) resemble those of O deficiency. Activity progressively falls to zero; "Limax" movement is maintained till inhibition occurs. Inhibition is reversible even after 40 hrs. in 10^{-4} *M* cyanide. The effects of cyanide on the amoebae are characteristic of its action on a respiratory mechanism. The minimal effective concentration lies between 10^{-5} and 10^{-6} *M*. Increasing the concentration to 10^{-4} *M* only slowly increases the effect. The effect of sulphides on the marine amoeba closely resembles that of cyanides. Alcohols and chloretone cause inco-ordination of amoeboid movement. At a certain liminal concentration movement becomes irregular, and it is inhibited by about 10 times this concentration. The effects do not resemble O deficiency. The effectiveness follows the series methyl < ethyl < butyl and chloretone < amyl. In the absence of O, cyanides do not affect the behavior of the amoebae. This agrees with the supposition that cyanides act upon the respiratory mechanism in the amoeba. Alcohols are even more effective in the absence of O than in its presence. Those anaesthetics (cyanides and sulphides) which induce effects resembling O deficiency in the amoeba are those which inhibit the cytochrome respiratory mechanism. It is suggested that the adverse effects produced by the anaerobic processes causing amoeboid movement are normally removed by an oxidative recovery process, which involves some respiratory mechanism similar to cytochrome.—*C. F. A. Pantin.*

[Movements of teleosts as related to experimental lesions of the peripheral motor and sensory apparatus.] *Boll. Soc. Ital. Biol. Sperim.* 5(6): 1026-1028. 1930.—Unilateral blinding is followed in *Julis vulgaris* and *J. giofredi* by an irregular bending of the tail and a homolateral bending of the body. Bilateral blinding causes the animals to keep in contact with the basin walls. No rotation or other movements were noticed.—*M. Comel.*

10022. SCHEMINZKY, FERDINAND. Weitere Untersuchungen über die Galvanotaxis von Echinodermen. *Pflüger's Arch. Ges. Physiol.* 226(3): 354-365. 2 fig. 1930.—A study of the galvanotactic response of a series of echinoderms. *Strongylocentrotus lividus, Asterias tenuispina, Astropecten bispinosus, Astropecten spinulosus, Asterina gibbosa, Asterias glacialis* and *Echinaster sepositus* all showed a response to the electric current although Nagel had previously reported that the last two give no reaction. *S. lividus* gives a monophasic anodal response; all the others display a diphasic type of galvanotaxis. The smaller forms require a greater current density for stimulation. The author points out the possibility of explaining the phenomena observed in galvanotaxis on the basis of permeability changes analogous to those resulting in electrically stimulated excised frog muscle, e.g., local cathodal fatigue, anodal recovery, etc.—*D. W. Bronk.*

10023. SCHEMINZKY, FERDINAND. Zur Analyse der zweiphasischen Galvanotaxis der Echinodermen. *Pflüger's Arch. Ges. Physiol.* 226(3): 366-376. 2 fig. 1930.—Certain echinoderms, e.g., *Solaster,* give a diphasic galvanotactic response, moving first toward the cathode, then after a pause toward the anode. The paper is devoted to an analysis of this spontaneous reversal of movement, previously observed by the author. The mechanisms of these two phases of the movement are fundamentally different. The 1st is due to direct action of the current on the organs of locomotion or to a local reflex in the individual arms. The 2nd or positive phase is essentially a reflex movement of the whole animal and is of the nature of an escape movement. In support of this view the author presents experiments which show that following transection of the nerve ring or partial asphyxia only the movement toward the anode is suppressed.—*D. W. Bronk.*

10024. **ADRIAN, E. D., and F. J. J. BUYTENDIJK. Potential changes in the isolated brain stem of the goldfish.** *Jour. Physiol.* 71(2): 121-135. 11 fig. 1931.—The goldfish was chosen because of the large size of its brain stem compared with that of the frog and also because of the greater activity of the respiratory centers. It was possible to record rhythmic potential waves of long duration (up to ¼ sec.), recurring at intervals of 1-3 sec. The respiratory movements have the same range of frequency, and the potential waves presumably coincide with the activity of the respiratory centre. Each wave is caused by the vagal lobes developing a negative potential with respect to other parts of the brain stem. The change is usually monophasic and of smooth contour, but small oscillations are occasionally present. Potential waves of various form may occur in the mid-brain. Some of these are of smooth contour, but often there are rapid oscillations (10-20 a sec.) superimposed on a much slower change. The oscillations resemble those obtained from a nerve trunk when a number of fibers are discharging rhythmically and more or less in unison. The slow potential waves may be due to nerve fibre discharges, but their form makes it more probable that they represent a slow change in the nerve cells or dendrites. It is pointed out that, if the nerve cells become depolarized when they are excited, a slow development and decline of the excitatory state would be accompanied by potential waves of the type described, and the axon discharge would rise and decline in frequency. The rhythmic activity of the respiratory centre in the goldfish can occur in the entire absence of sensory impulses.

10025. **ALTSCHUL, RUDOLF. Contributo biologico allo studio della patoclisi. [Biologic contribution to the study of pathoclisis.]** *Bull. e Atti R. Accad. Med. Roma* 55(7): 147-151. 1929.—"Pathoclisis" is the term which sums up the theories of Ehrlich and C. and O. Vogt as to the differing physico-chemical properties of the different nervous systems. Altschul draws on these theories to explain a differential Au staining of the dentate nucleus and the surrounding cerebellar substance.

10026. **AMBERSON, WILLIAM R., ARTHUR PARPART, and GERTRUDE SANDERS. An analysis of the low-voltage elements of the action-potential wave in nerve.** *Amer. Jour. Physiol.* 97(1): 154-179. 1931.—By a direct method of analysis the low-voltage elements of the action-potential wave in nerve were studied, and the voltage and duration of the negative after-potential were approximately determined. The main observations were: (1) In resting nerve the low-voltage elements are very much reduced or absent; after activation of the tissue by a period of repetitive stimulation they become highly developed so that the electrical discharge from the negative after-potential may be 4-10 times as great as that from the initial high-voltage "spike." (2) The negative after-potential and the "after positivity" are very much reduced at low temp. (5° C. or below), even though the nerve is continually activated by repetitive stimulation. (3) During O-lack the low-voltage elements, both positive and negative, disappear after 1-2 hrs., so that the action potential wave consists of the high-voltage phase alone. The latter may continue for more than an hr. after the suppression of the low-voltage phase. Upon readmission of air the low-voltage elements soon reappear, and become very highly developed, often rising far above the values previously observed in the fresh nerve. The high-voltage phase shows no such behavior, merely returning to, or nearly to, its original value. (4) Direct analysis of the electrical discharge from 2 waves, separated by an interval (10 σ) just longer than the relative refractory period, shows that while the high-voltage phases of the 2 waves come through without diminution, the low voltage elements interfere over all, or nearly all, of their extent, so that the electrical discharge from the negative after-potentials of the 2 waves together is less than double that given by a single wave alone. The differing behaviors of these 2 elements of the action potential wave are interpreted to mean that they are the electrical signs of 2 separate processes. It is concluded that the low-voltage after-potentials are the electrical sign of an active second process, restorative in nature, which builds the nerve back to its original state, possibly by replenishing the stock of some material whose breakdown is responsible for the high-voltage phase. This first process, underlying the high-voltage phase, is relatively anaerobic, and slightly affected by various physical and physiological changes. The second process is relatively aerobic, and is sensitively related to a variety of factors. This conception is similar to the idea long ago proposed by Hering in explanation of the "after-positivity" after repetitive stimulation, but differs from that suggested recently by Levin, who believes that the after-potentials arise from an accumulation of chemical metabolites during activity. The authors believe that the mere presence of such products has no effect upon the action potential wave, although they may affect the injury potential, but that the after-potentials arise only when these substances are being removed, or, more probably, when a new store of precursor substance is being formed, by direct chemical action. A possible relationship between such chemical changes and the physical state of the membrane is suggested, according to which fluctuations in the pH of the tissue affect the dissociation state of an ampholyte near its isoelectric point, and so alter the value of the membrane potential by changing the membrane charge.—*Authors' summary.*

10027. **BABKIN, B. P., and MARGARET E. MacKAY. Concerning the motor mechanism of the salivary glands.** *Amer. Jour. Physiol.* 91(2): 370-376. 1930.—Motor phenomena under the influence of the stimulation of nerves and action of histamine could be observed in the submaxillary gland of both dogs and cats. No smooth muscles could be found either in the ducts or elsewhere in the gland. The possibility of contraction of other histological elements is discussed. The cervical sympathetic nerve besides secretory fibres possesses motor fibres for the submaxillary gland. No adequate explanation can be given at present for the motor effect produced by the stimulation of the chorda tympani.—*Authors' summary.*

10028. **BACQ, Z. M. The action of abdominal sympathectomy on the growth of the albino rat and the weight of the genital organs.** *Amer. Jour. Physiol.* 95(3): 601-604. 1930.—Removal of the 2 abdominal chains from young albino rats has no influence on the later growth of the tail and hind limbs. An increased weight of epididymides, seminal vesicles and prostate was observed in 4 sympathectomized ♂♂; the weight of the ovaries, uterus and tubes in 2 sympathectomized ♀♀ was also much above the normal.—*Author's conclusions.*

10029. **BARDENSTEIN, SARA. Über nervöse Wechselbeziehungen der Nebennieren und des Paraganglion**

abdominale mit den anderen Organen der Bauchhöhle bei der Katze. *Anat. Anzeiger* 71(1/3): 37-54. 1 fig. 1930.—In 30 cats Bardenstein found that the abdominal paraganglion and the suprarenal, as in man, had "short" routes of nervous connection with some sections of the gastro-intestinal tract and its large glands, with the sexual glands, the kidneys, the diaphragm, the vascular system, the peritoneum, and the peritoneal cellular tissue. The "short" nerve routes of the suprarenals varied from barely pronounced to complete. Those of the abdominal paraganglion showed those constants which appear usual for the autonomic nervous system.

10030. **BISHOP, GEORGE H.** The reactance of nerve and the effect upon it of electrical currents. *Amer. Jour. Physiol.* 89(3): 618-639. 10 fig. 1929.—The "capacity" of nerve is discussed in terms of the polarizability of its interfaces to ions. A network of capacity and resistance is described which in 1 arm of a Wheatstone bridge balances the reactance of nerve in the opposite arm, when the Pb electrodes are in contact with intact tissue. The distribution of polarizability in nerve is inferred to be different from the distribution of the reactance in this network, but to involve more than 1 component, such that no single unit of 1 capacity and resistance will compensate nerve in a bridge. By means of the visible cathode ray oscillograph record it is feasible to measure the reactance of a stretch of nerve mounted on electrodes with a galvanic current of short duration, to differentiate qualitatively between its different components of polarizability, and to measure its resistance to direct current, and to alternating currents of (practically) infinite frequency. The reactances of nerve trunks, and of roots with thin connective tissue sheaths, are found to be similar in distribution. The effect of the sheath is chiefly due to its resistance, in series transversely, and in shunt longitudinally, to the nerve fibers. The effect of injury under 1 or both electrodes, by heating, by crushing, or by repeated electric shocks, is to reduce 1 component chiefly of the nerve's reactance, with little effect on the others. Injury in the interpolar stretch reduces a different component. The action potential is decreased to extinction, and the threshold is raised, progressively, through injury by electrical shocks, considerably before the transverse polarizability of the nerve under the electrodes is abolished; further injury by shocks of the same strength then further reduces the polarizability to approximately zero at the region injured. Certain apparatus suitable for the measurement of resistance and capacity with the oscillograph as a null instrument is described in an appendix.—*Author's summary.*

10031. **BLIER, ZACHARY.** Physiology of the sphenopalatine ganglion. *Amer. Jour. Physiol.* 93(2): 398-406. 1 fig. 1930.—The vasomotor reactions in the nasal mucosa were measured by the method of Tschallussow, which depends upon changes in volume of the nasal cavity. It was found that in the dog vaso-constrictor fibers for the nasal mucous membrane travel as follows: the preganglionic fibers run in the cervical sympathetic and synapse in the superior cervical ganglion. The post-ganglionic fibers go to the internal carotid nerve; the major portion of them join the posterior nasal nerve and reach the nasal mucous membrane with this nerve. A small number reach the deep petrosal, go to the Vidian nerve, traverse the sphenopalatine ganglion, and reach the nose by way of the posterior nasal nerve. In the dog vaso-dilator fibers for the nasal mucous membrane travel in 2 ways: a) from the facial nerve the preganglionic fibers travel in the major superficial petrosal to the sphenopalatine ganglion, where they undergo a synapse. The post-ganglionic fibers enter the posterior nasal nerve and go to the nose. b) Vaso-dilators run in the cervical sympathetic and probably synapse in the superior cervical ganglion. From here they travel in the internal carotid nerve, to the posterior nasal nerve, and reach the nasal mucous membrane. No antidromic vaso-dilators are present in the posterior nasal nerve of the dog. Sensory nerves for the nasal mucous membrane are visceral and somatic. The visceral fibers run through the sphenopalatine ganglion to the Vidian nerve to the greater superficial petrosal nerve to the facial nerve. The somatic fibers run in the posterior nasal nerve of the trigeminus. Both sets of fibers are capable of producing respiratory, cardiac, ocular, facial, and lingual reflexes. Reflex vasomotor changes in the nasal mucous membrane can be evoked by stimulation of the Vidian nerve, posterior nasal nerve and others. There are no sensory fibers in the cervical sympathetic of the dog. These findings on the dog do not seem to help in explaining effects reported from cocainizing the sphenopalatine ganglion in man.—*Author's conclusions.*

10032. **BRJUSSOWA, S. S., und W. W. LEBEDENKO.** Zur Schmerzleitungsfähigkeit der Gefässe. *Zeitschr. Ges. Exp. Med.* 69(1/2): 29-40. 1929.—This research has been done in order to settle the dispute between the anatomists and physiologists as to whether the innervation of the vessels is through branches of the spinal nerves or long periarterial branches in the walls of the vessels. Previous varying results have been due to the acute experimentation. The authors measure the pain by the crying and movements of the animal, the pulse, blood pressure, and respiration. Electrical, mechanical, or chemical stimuli (injection of 5% $BaCl_2$) are employed 2-7 days following the operation instead of in an acute experiment. After section of the spinal nerves sending fibers to the vessels complete anesthesia results; this is in opposition to the view that there are long periarterial paths and also not in accordance with the work of Foerster on patients. Cutting the posterior roots eliminates pain, but it is essential that a sufficient number be cut. Hemisection of the cord weakens the pain reaction. The writers conclude: there is no pain conduction on section of all the mixed peripheral nerves, or the posterior roots, or bilateral section of the proximal cord. —*W. H. Gantt.*

10033. **BRODMAN, KEEVE, and McKEEN CATTELL.** Heat versus tension in relation to the problem of plurisegmental innervation. *Jour. Physiol.* 70(3): 205-217. 1930.—In the gastrocnemius muscle of the frog, preparations in which the sum of the tensions (T) resulting from the separate stimulation of the 8th and 9th nerve roots (T_a+T_b) considerably exceeds the value obtained from their simultaneous stimulation (T_{a+b}) give values for the initial heat (H) such that (H_a+H_b) approximates (H_{a+b}), as was observed by Katz. On the other hand, if the excess tension $(T_a+T_b)-(T_{a+b})$ is low, the heats measured for the separate roots (H_a+H_b) fail to equal the value obtained when the whole nerve is stimulated at once (H_{a+b}). This suggests that a smaller proportion of the heat produced is recorded when both roots are stimulated together, and consequently that heat measurements do not serve as a reliable criterion of doubly innervated muscle fibers. The indicated proportion of plurisegmentally innervated fibers $((T_a+T_b)-(T_{a+b}))$ becomes smaller as the observations are repeated, i.e., as fatigue develops. In 1 group of experiments the average number was reduced to less than ½ the original indication, during a period which resulted in a reduction of the power of the muscle (T_{a+b}) to about ⅓. This result can be accounted for on the basis of the functional loss of a chance distribution of neuro-muscular junctions, and it undoubtedly explains many instances in which a low proportion of plurisegmentally innervated fibers has been indicated by tension. The change in the value of the excess tension $((T_a+T_b)-(T_{a+b}))$ which may occur in a given preparation, as well as the wide differences observed between different preparations, rule out the suggestions advanced by various workers that the excess tension can be wholly accounted for by a decrease in the proportion of tension registered when both roots are stimulated together (T_{a+b}). These results indicate that tension records give a reliable approximation of the proportion of fibers in a muscle having functionally active nerve endings from both nerve roots.—*Authors' summary.*

10034. **BRONK, D. W.** The initial and recovery heat

production of vertebrate nerve. *Jour. Physiol.* 71(2): 136-144. 1931.—Recent improvements in thermopile and galvanometer design have been employed in a determination of the course of the heat production of frog's nerve. Many of the essential findings of the earlier workers have been in large part confirmed. An analysis of the course of the heat production resulting from a 9- to 15-sec. stimulus shows a progressive increase in the rate of heat production during the period of stimulation. This is the sum of the heat associated with the conduction process and that accompanying the recovery therefrom. The recovery heat production has a maximum rate immediately following the end of stimulation, and continues for some min. at a decreasing rate. The duration of this recovery phase is largely dependent upon the temp. At 19° C. it was about 11 min. and at 24°-25° C. about 7½ min. From 7 experiments comprising about 70 individual determinations the initial heat production has been found to be 8.9% of the total. This is compared with the earlier determinations of 11% for frog's nerve and Hill's recent value of 2.25% for crustacean nerve.—*Author's summary.*

10035. BROWN, GEORGE E. Observations on the surface capillaries in man following cervicothoracic sympathetic ganglionectomy. *Jour. Clin. Investigation* 9(1): 115-137. 6 fig. 1930.—Quantitative studies on the capillaries of the skin of human beings have been made both before and after cervicothoracic sympathetic ganglionectomy. Nine cases of advanced Raynaud's disease, 4 of vasomotor forms of scleroderma, 4 of primary scleroderma, 2 of thrombo-angiitis obliterans, and 1 of arthritis of the hands have been studied. The operation did not cause dilatation of the capillaries (the usual physiologic effect) in any case. On the contrary, there was consistent narrowing of the dilated atonic capillaries in Raynaud's disease, and an increase in the number of visible capillaries. This could be explained on the basis of a diminished concentration of a theoretic chemical dilator substance in the tissues. Following sympathetic ganglionectomy in 8 cases of vasomotor and primary forms of scleroderma, there was definite reduction in the caliber of the capillaries. The number of open capillaries for each sq. mm. of skin increased. There was quantitative evidence of arteriolar dilatation and lessened response on the part of these vessels to cold. Clinical improvement of some degree occurred in every case. In the cases of thrombo-angiitis obliterans and arthritis, in which the capillaries were of fairly normal caliber and tonus, following operation no change in the width of the capillaries was noted. The intermittent slow flow of cyanotic capillary blood changed to one that was rapid, regular, and of normal color. The number of open capillaries was increased. The major effect of sympathetic ganglionectomy is exerted on the arterioles. There is a sharp, maintained increase in the surface temp. of the skin of the hand in every case. These studies add some confirmation to the opinions of those who hold to the importance of chemical factors in modifying tonus in the capillaries of the skin of human beings. Chemical control of these vessels seems, under certain conditions, more effective than nervous control.—*Author's summary and conclusions.*

10036. BURGET, G. E., and W. K. LIVINGSTON. Pathway for visceral afferent impulses from the forelimb of the dog. *Amer. Jour. Physiol.* 97(2): 249-253. 1931.—Injection of 5% lactic acid into the brachial artery of a dog gave rise to afferent impulses which apparently were painful to the animal. This reaction is dependent upon changes in the vessel wall rather than upon secondary changes in somatic tissues. Removal of the stellate and 2nd thoracic ganglia on one side did not alter the response of the animal to injection of lactic acid into the brachial artery of that side. These visceral afferent impulses enter the cord largely by way of the posterior roots of the 7th and 8th cervical and 1st dorsal nerves. —*Authors' conclusions.*

10039. CATTELL, McKEEN, and KEEVE BRODMAN. The influence of the number of active fibres on the heat-tension ratios of striated muscle. *Jour. Physiol.* 70(2): 195-203. 1930.—The relative amount of heat and tension measured, as the result of the application of a short tetanic stimulus to the gastrocnemius muscle of the frog through its nerve, changes as the strength of the current is varied between its threshold and maximum value. In 7 preparations the average value of the heat-tension ratio increased more than 50% as the tension increased from a low value to the maximum. Since the muscle was always stimulated through its nerve, this result is not due to a primary influence of the current strength on the physiological response of the muscle, but rather to the changing number of active fibres. Various factors which might account for the increasing value of the heat-tension ratios as more fibres are involved are discussed, and it is suggested that the explanation lies in the difficulty in measuring a constant proportion of the tension or heat produced when a changing number of fibres are active.—*Authors' summary.*

10040. CHILOW, K. L. Über einige Indikatoren bei der Untersuchung der reflektorischen Nasenfunktion. [Some indicators in the investigation of reflex nasal function.] *Beitr. Anat. Ohres. Nase u. Halses* 28(2): 124-137. 1930.—The action of increasing intensities of odor (geraniol, citral, chinolin, pyridin, acetone, and toluol in the order given) on the respiratory and cardiovascular reflexes was tested on 12 surgically prepared rabbits. Mechanical stimulation by pure air produced no cardiovascular reflex in the nasal mucosa. In the odor experiments the cardiovascular reflex was a secondary phenomenon, dependent on the respiratory reflex. All the odors produced slowing or standstill of respiration while the olfactory bulb was in situ; thereafter only toluol and acetone produced a reaction. Another series of aromatics was also without action after extirpation of the olfactory bulb. When the Gasserian ganglion was also removed acetone and toluol had no effect. Individual degrees of sensitivity were found but all rabbits responded to toluol with respiratory standstill.

10041. CLEMINSON, F. J. Limb responses to semicircular canal stimulation in man. *Acta Oto-Laryngol.* 15(2/4): 393-397. 3 fig. 1931.—A patient with total deafness of the left ear following mumps, tested 3 wks. after onset of the disease for equilibrium-maintaining reflexes, gave reactions exactly corresponding to those described by Tait and McNally in the case of frogs in which the left anterior and posterior semicircular canals had been destroyed. After 11 wks. more, though hearing and caloric tests showed no recovery of the labyrinth, no difference was found between the responses of the right and left limbs. Apparently in some way compensation had been established.

10042. COATES, A. E., and O. W. TIEGS. Further observations on certain alleged effects of sympathetic nerves on skeletal muscle. *Australian Jour. Exp. Biol. and Med. Sci.* 71(1/2): 37-40. 1930.—In the brachial plexus of the pigeon the sympathetic ganglia are so intimately associated with the spinal nerves that postural effects following upon removal of these ganglia may be ascribed to unavoidable injury of spinal nerves, and not to removal of the ganglia alone. The histological structure of the interosseus muscles of a dog was not visibly affected by deprivation during a year of the sympathetic supply nor was there a change in thickness of the fibers. Contrary to Royle, the authors found that the sympathectomized limb of a goat did not behave differently from the normal limb on injection of ephedrine into the jugular vein. Apparent lack of tone in the sympathectomized limb, occurring in 1 out of 10 goats in which the left sympathetic trunk was removed and allowed to

degenerate for 3 mos., seemed to be due to trauma, and not to removal of sympathetic nerves.

10043. **COOK, D. D., and R. W. GERARD. The effect of stimulation on the degeneration of a severed peripheral nerve.** *Amer. Jour. Physiol.* 97(3): 412-425. 2 fig. 1931.—A method for the continued stimulation of nerves in situ in living animals by means of buried electrodes was used on dog sciatics to study the course of degeneration of the peripheral portion of a severed nerve under stimulation. A cut nerve lost its ability to conduct more rapidly when stimulated than when at rest. Data on irritability and muscle response lead to the conclusion that individual axones fail in temporal sequence. In each axone the threshold rises, and conduction is probably depressed, until it has passed a critical value at some point along the fiber, when conduction is blocked. Degeneration of a nerve process isolated from its cell body might be due to lack of impulses conducted by it or of necessary substances spreading along it. The evidence considered favors the 2nd possibility.—*Authors' summary.*

10044. **CORBEILLE, CATHERINE, and EDWARD J. BALDES. Changes in volume of the spleen in response to acoustic stimulation.** *Amer. Jour. Physiol.* 91(2): 499-506. 1930.—In dogs and in 1 cat the changes in volume of the spleen were studied by the plethysmographic method of Hargis. Environmental conditions of the animals were carefully controlled. External evidences of emotional response were not noted at any time. The splenic responses to acoustic stimuli followed certain definite types: sudden contractions with the onset of the stimuli, delayed sudden contractions occurring during the stimuli, sudden contractions following cessation of the stimuli, slow contractions during the stimuli, and persistent contractions and dilatations. These reactions have some of the characteristics of general reflexes described by Sherrington.—*Authors' summary.*

10045. **CRILE, GEORGE W. An electro-chemical interpretation of memory.** *Proc. Amer. Phil. Soc.* 69 (6): 359-369. 3 pl. 1930.—A theory is advanced which seeks to explain the faculty of memory on the basis of an electrical balance of the K-phospho-lipins of the nerve cells and their fibers. Due to stimuli received from the outside, electrical changes are produced along afferent nerves. These are carried to the nerve cells of the infant and condition a "secretion" of the neurofibrils. Experiments are reported in which elements that can be shown to be chemical components of brain substance when subjected to electrical stimulation tend to arrange themselves in a fashion which the author considers to be similar to the neurofibrils in the brain. The author considers his experiments as proof of the fact that memory and other intellectual faculties are based on these electrical properties of brain tissue.—*W. Malamud.*

10046. **DALE, H. H., and J. H. GADDUM. Reactions of denervated voluntary muscle, and their bearing on the mode of action of parasympathetic and related nerves.** *Jour. Physiol.* 70(2): 109-144. 1930.—For experiments on denervated voluntary muscles with their natural vascular supply the authors have used the musculature of the tongue and the gastrocnemius of cats and dogs. The apparent difference between the actions of epinephrine on "drug contractures" and "nervous contractures" of denervated muscles was investigated and explained. It was found that eserine greatly enhances the contractures produced by stimulating vaso-dilator nerves and those produced by choline esters, but leaves unchanged those produced by analogous non-esteric substances (tetramethyl ammonium salts). Atropine paralyses the effect of acetylcholine and similar drugs, applied directly to denervated mammalian muscle. The evidence removes discrepancies and produces new concordances, supporting the view that the vaso-dilator effects of parasympathetic nerves and of sensory fibres stimulated antidromically, and the contractures of denervated muscles accompanying these actions, are due to the peripheral liberation of acetylcholine.

10047. **DWORKIN, S., and M. FLORKIN. The effect of temperature upon chronaxie and recovery period of nerve.** *Amer. Jour. Physiol.* 95(1): 139-141. 1930.—The effect of cooling the nerve upon least interval for muscular summation and duration of chronaxie has been studied in the sciatic-gastrocnemius preparation of *Rana pipiens.* Both processes are prolonged in a fairly uniform manner; a ratio of 6 to 1 appears to hold at any given temp. Making use of the data of Amberson, a ratio of 4 to 1 between absolute refractory period and chronaxie is disclosed. The significance of these relationships is not discussed.—*Authors' summary.*

10048. **ENGERTH, GOTTFRIED, und HANS HOFF. Ein weiterer Beitrag zur Lehre von der Stirnhirnfunktion.** *Zeitschr. Ges. Neurol. u. Psychiatr.* 129(3/4): 332-341. 1 fig. 1930.—Other investigators had shown that dogs in which the pyramids had been sectioned, dogs from which the cerebellum had been removed, and animals from which the cerebrum but not the thalamus had been removed, preserved the normal rhythm in walking (in dogs, either a trot with diagonal extremities advanced, or a gallop). In 6 dogs from which large parts of the cerebrum had been removed, Engerth and Hoff found that a cut in front of the corpora quadrigemina anteriora produced spastic gait ["Laufkrämpfe"], while a posterior cut did not, even though it severed the nucleus ruber completely from the brain stem. In a 2nd experiment the basal portion of the brain stem was cut in an anterior-posterior direction, and thereby the crossed fibers from the nucleus ruber to the spinal cord were severed. One of the 2 dogs used died; the survivor could not walk. It could move its legs, but correlation between the 2 sides was completely lost. The authors conclude that the nucleus ruber is an important center regulating quadrupedal walking, but that the gait is modified (probably differently for the various animal species) by the higher centers. That the frontal lobes affect the human quadrupedal gait was indicated by several series of experiments. First, a "large number" of healthy persons were made to walk on all fours, with knees bent and palms and soles flat on the ground. The arm and leg of first 1 side and then the other were advanced. Is this ambling gait congenital or acquired during development? Children just beginning to walk were observed to advance simultaneously the left foot and right hand, then the right foot and left hand, until the 2nd yr. of life, when the gait changed to that previously observed in adults. Engerth and Hoff believe that they have observed signs of a connection between this change and the development of the faculty of speech: children who are backward in learning to talk retain the primitive trot gait longer than children whose speech development is normal. The authors conclude that the development of the human walk depends on a switching of control from the deep centers to the superficial motor centers in the frontal lobes of the cerebrum. In 2 patients with lesions of the frontal lobes Engerth and Hoff were able to demonstrate a reversion of the quadrupedal gait to the primitive crossed advance. They explain the ambulation apraxia observed by Gerstmann and Schilder as probably due to incomplete destruction of the frontal centers, so that what remained was enough to prevent the deep centers from assuming control, but not enough itself to regulate the act of walking.

10049. **[ERSHOV, V. A.] ЕРШОВ, В. А. Экстензорная корковая ригидность и функции предлобных долей головного мозга. [The extensor cortical rigidity and functions of prefrontal lobes of brain.]** [English summary.] Клинический Журнал Саратовского Университета (*Klin. Zeitschr. Univ. Saratow*) 8(4/5): 211-228. 1 fig. 1929.—The author's experiments were conducted on 14 dogs. Prior to operation, dogs were deprived for an entire day of food and water. 30-60 min. before the operation, solution of morphine chloride was injected subcutaneously. The animals were anesthetized with chloroform-ether. Motor areas of the cerebral cortex and prefrontal lobes of the brain (in front of *sulcus cruciatus*) were removed together or separately. In animals No. 2-5, extirpation was performed on the left

side; in No. 6-8, 10-13—on the right; No. 1, 9, 11—only frontal lobes were removed. Dogs were observed after the operation from 2-5 days to 3-5 weeks. In all cases there was paralysis of legs on the opposite side, and derangement of cutaneous and deep sensitivity, persisting for 2-3 weeks. No. 1, 3, 8 showed cutaneous hypersensitivity (scratch reflex) on the side of operation. There was also observed extensor rigidity of limbs—especially of forelegs—on the opposite side. This rigidity remained for about 35 days, although decreasing gradually after 7th-8th day. Its intensity depended on the position of the animal's head in relation to the body. Removal of prefrontal lobes alone resulted in profound depression, circular movement towards the side of lesion, and, in many cases, in scratch reflex on the ipsilateral side. Distinct extensor rigidity, especially in the forelegs, was marked on the opposite side. The author concludes that the motor areas and prefrontal lobes of the brain share the function of supreme control of the static and stato-kinetic reflexes (postural reflexes).—*B. Van Rosen.*

10051. **FORBES, A., H. DAVIS, and E. LAMBERT. The conflict between excitatory and inhibitory effects in a spinal center.** *Amer. Jour. Physiol.* 95(1): 142-173. 3 fig. 1930.—The balancing of excitatory and inhibitory central effects in the extensor center has been studied by isometric recording of contraction in the knee extensor, vasto-crureus, in the decerebrate cat. The effective strength of the inhibitory stimuli has been controlled by simultaneous recording of action currents in the ipsilateral afferent nerve. Maximal stimulation of the ipsilateral (peroneal or popliteal) nerve causes complete inhibition of the strongest crossed extension reflex. Submaximal stimulation causes complete inhibition of weak crossed extension reflexes, but as the strength of the excitatory stimulation is increased, the amount of inhibition passes through a maximum and then decreases, in this respect resembling the relation found by Creed and Eccles with the crossed inhibition of flexors. Increasing the excitatory background against which the the submaximal inhibitory stimulus operates, not merely adds more motor neurones to the number previously involved, but robs the inhibitory stimulus of the power to inhibit as many motor neurones as it did when acting against the weaker excitatory background. Weak stimulation of the popliteal nerve, which causes inhibition against a weak excitatory background, sometimes, in the presence of a strong excitatory background, gives instead additional excitation. The authors' observations of the rebound contraction which follows strong inhibitory stimuli, tend to support the interpretation of this phenomenon, proposed by Sherrington and Sowton, as the delayed expression of activity of excitatory fibers in the ipsilateral nerve. The threshold of these fibers is relatively high. Evidence is also adduced for the presence of inhibitory fibers of high threshold in the contralateral sciatic nerve. The balance between excitatory and inhibitory influences is rarely steady. One or the other usually tends to dominate. The intrinsic tendency of the spinal centers to exhibit a spontaneous alternation between extension and flexion, even in the absence of proprioceptive impulses, demands some postulate other than the simple grading of opposed excitatory and inhibitory states, acting like chemical substances. Evidence at present known, pointing to the view that central excitatory and inhibitory effects are qualitatively different from those associated with peripheral nerve impulses, is discussed and shown to be compatible with an interpretation based on known functions of peripheral nerve. Sherrington's theory, which assumes a "central inhibitory state" of undetermined character, requires fewer subsidiary hypotheses and is simpler in this respect, but must still be regarded as merely a working hypothesis.—*Authors' summary.*

10052. **FULTON J. F., E. G. T. LIDDELL, and D. McK. RIOCH. The influence of experimental lesions of the spinal cord upon the knee-jerk. I.—Acute lesions.** *Brain* 53(3): 311-326. 10 fig. 1930.—One of the major physiological symptoms of spinal shock is an increased susceptibility to inhibition. The knee-jerk, for example, may be inhibited for a period of several sec. by applying a single break-induction shock to a sensory nerve of the hind-limb. In the intact animal, or in a decerebrate preparation, it is exceedingly difficult and often impossible to inhibit a knee-jerk by a corresponding stimulus. The present paper records experiments in which the attempt was made to determine the pathways responsible for the differences between the decerebrate and spinal condition, as judged by the inhibition of the knee-jerk. Acute lesions were made at levels ranging from D.8 to L.1, after which knee-jerks were examined by means of a frictionless torsion-wire myograph of high natural vibration frequency, with simultaneous registration of the electrical response according to the technique described by Ballif, Fulton and Liddell. Complete lateral semisection of the spinal cord causes the knee-jerk on the side of the semisection to assume "spinal" characteristics, while the jerk on the opposite side remains "decerebrate." The dorsal $\frac{2}{3}$ of the spinal cord may be cut through without causing the knee-jerk to become "spinal" in type on either side. In acute preparations isolated transections of the ventral quadrant of the spinal cord on 1 side cause the knee-jerk on the same side to become "spinal." From these observations the authors conclude that the descending pathways responsible for the differences between the "decerebrate" and "spinal" conditions pass in the ventral quadrant of the spinal cord, probably in the medial $\frac{1}{2}$. The vestibulospinal tracts therefore suggest themselves since they are the most important descending fibres in this area. Transection of the spinal cord caudal to the knee-jerk centers causes great enhancement in their activity, diminution in susceptibility to inhibition, and, in a "spinal" preparation, the prompt reappearance of the stretch reflex.—*Authors' summary.*

10053. **FULTON, J. F., E. G. T. LIDDELL, and D. McK. RIOCH. The influence of unilateral destruction of the vestibular nuclei upon posture and the knee-jerk.** *Brain* 53(3): 327-343. 3 fig. 1930.—Experiments on cats indicate that experimental lesions of the vestibular nuclei in normal animals cause hypotonia on the side of the lesions with forced rolling movements to that side. If decerebrated after an interval of 3 wks., the rigidity and stretch reflexes are greatly diminished on the injured side, and the knee-jerk is more readily inhibited. Marchi staining of the cord in such animals has shown extensive degeneration of the homolateral vestibulospinal pathway and slight degeneration in the crossed vestibulospinal tract. Acute lesions of Deiters' area after decerebration also cause great diminution of rigidity on the same side and increased susceptibility of the knee-jerk to inhibition. The authors conclude that the nucleus of Deiters and the direct spinal pathway to which it gives rise are chiefly responsible for the differences between the decerebrate and the spinal condition, and hence its integrity is essential for preventing spinal shock.—*Authors' summary.*

10055. **GELLHORN, E., H. GELLHORN, and J. TRAINOR. The influence of spinal irradiation on cutaneous sensations. I. The localization of pain and touch sensations under irradiation.** *Amer. Jour. Physiol.* 97(3): 491-499. 1931.—In 8 subjects for experiments with pain points and 4 for experiments with touch points, the localizations of pressure and pain points underwent characteristic changes when a spinal irradiation was brought about by pinching up a small area on the forearm. The accuracy in localization of pain points was

improved while the localization of touch points was impaired. These changes were not produced by changes in threshold since they were independent of the intensity of the stimulus. The experiments indicate that an alteration of the sensory part of the spinal cord is inadequately described by hyper- or hypo-esthesia, because qualitative changes in the sensations which lead to quantitative deviations in the accuracy of localization are not taken into account. The importance of the experimental results for the physiology and patho-physiology of the spinal cord is briefly discussed.—*Authors' summary.*

10056. **GLEY, E., et H. JANKOWSKA. Relation de dépendance entre la teneur du sang en calcium et l'action inhibitrice du nerf splanchnique.** *Jour. Physiol. et Path. Gén.* 28(4): 789-799. 8 fig. 1930.—The inhibitory effect of the splanchnic nerve on the movements of the intestine depends, like its vasomotor effect, on the Ca content of the blood. Hypocalcemia causes a great decrease and often temporary suppression of the inhibitory action of the nerve, which is rapidly regained by injections of $CaCl_2$ into the blood stream. In some animals the two functions of the splanchnic nerve can be differentiated by varying the Ca content of the blood.—*W. R. Fearon.*

10057. **GRIFFIN, ALBERT M., and WILLIAM F. WINDLE. The relation of the level of transection of the brain stem to the occurrence of decerebrate rigidity in newborn rabbits.** *Amer. Jour. Physiol.* 97(3): 397-404. 1931.—In 29 rabbits aged 1 hr.-9 days the cerebral hemispheres were removed and the brain stem sectioned, in different animals, at 3 principal levels. Decerebrate extensor rigidity occurred if the brain-stem was transected in a plane passing through the superior colliculi and the rostral ⅓ of the pons; the red nuclei and associated centers in the mesencephalon were separated from the functional portion of the central nervous system by such an operation. If the plane was slanted forward to the infundibulum or mammillary bodies, the red nuclei remained intact and marked decerebrate rigidity did not occur; instead, prolonged movements of progression characterized the experiment. It is evident that the postural reaction in young rabbits is independent of the red nucleus. Successful locomotion in these animals seems to require that this structure and possibly others in the hypothalamus remain intact. When the level of transection was made through the hind brain in the region of the nuclei of the 8th nerve, extensor rigidity disappeared and it was usually replaced by a marked flexor rigidity. Hence it is concluded that the occurrence of decerebrate rigidity in young rabbits is more dependent upon the level of transection of the brain-stem than upon the age of the animal.

10058. **HEINBECKER, PETER. The functional analysis of a sympathetic ganglion of the turtle by the cathode ray oscillograph.** *Amer. Jour. Physiol.* 93(2): 384-397. 2 pl. 1930.—Conduction through the cervical sympathetic ganglia of the turtle of the fiber types present in this nerve was studied in *Chrysemis picta, C. marginata* and *Pseudemys concinnata.* The nerve lacks the 1st component of fibers characteristic of somatic nerves. The 1st, or B_1, potential of this nerve when present pre- and postganglionically conducts through the ganglion in both directions without apparent delay. This fact, together with the evidence that the fibers giving rise to it have physiological and histological characteristics similar to those of fibers considered to be afferent in autonomic and somatic nerve trunks, seems to warrant the conclusion that the fibers of the B_1 potential are afferent. The major portion of the fibers of the B_2 potential and all fibers giving rise to the C potential synapse in the superior sympathetic ganglion. The action potentials of such fibers do not conduct toward the central nervous system through the ganglion. In turtles having 1 or more proximal ganglia besides the customary superior a small number of B_2 fibers conduct through the superior cervical ganglion in both directions without delay. These fibers have synapsed in the more proximal ganglia. Postganglionically they conduct more slowly than the rest of the B_2 fibers. No evidence of afferent C fibers has been obtained. In the turtle superior cervical ganglion, preganglionic myelinated or B_2 fibers are found to synapse with postganglionic myelinated or B_2 fibers, and unmyelinated C preganglionic fibers to synapse with unmyelinated C postganglionic fibers. In fresh preparations the synapse time as determined by delay in conduction rate and by absolutely refractory period times varies from 8 to 15 σ for the B_2 potential and from 20 to 30 σ for the C potential. These times are proportional to their respective thresholds and conduction rates. A method for determining the presence of a synapse in a ganglion by the use of CO_2 is described.—*Author's summary.*

10059. **HENDERSON, V. E., and T. A. SWEET. On the respiratory centre.** *Amer. Jour. Physiol.* 91(1): 94-102. 1929.—Experiments (of which 5 are cited) on decerebrated cats indicate that the respiratory centre is located in the lower part of the medulla. Respiration is affected by the increase in tonus caused by the activity of the medullary tonus centres when the impulses from the red nucleus are cut off but not deleteriously as long as the vagus nerves are functional. Cutting off of the impulses from the red nucleus and from the lungs by cutting the vagi leads to apneustic respiration. The work of the authors shows no evidence for more than 1 respiratory centre.

10060. **HERREN, R. YORKE, and HAROLD R. FOSSLER. Achilles and crossed flexion reflex time in the intact rat.** *Amer. Jour. Physiol.* 97(2): 282-285. 1931.—In 6 mature ♂ rats weighing 170-200 gm. light dosages of caffeine citrate lengthened Achilles reflex times but did not affect crossed flexion reflex times. Heavy dosages of caffeine citrate gave an Achilles reflex time similar to the normal but greatly shortened crossed flexion reflex time. Light dosages of alcohol shortened Achilles reflex time but did not affect crossed flexion reflex time. Heavy dosages of alcohol lengthened Achilles reflex time and also greatly lengthened crossed flexion reflex time.

10062. **HINSEY, J. C., S. W. RANSON, and E. A. DOLES. Reversal in the crossed extension reflex in decerebrate, decapitate and spinal cats.** *Amer. Jour. Physiol.* 95(3): 573-583. 1930.—Contralateral reflexes have been examined in the muscles acting at the ankle joint, in 14 decerebrate, 4 decapitate and 19 spinal cats. The state of neural balance in the spinal centers is a very important factor in determining the type of reflexes present. Reversals have been seen in a great many of these preparations. Weak stimuli usually elicit extension reflexes and stronger ones tend to bring in flexion. Changes in reflex type were found on changing the nerve stimulated. The saphenous nerve gave crossed extension in the anemic decerebrate preparations while the tibial at the ankle and the femoral at times showed flexor involvement either as contraction, alternate contraction or pure crossed flexion. Similar reversals were seen in decapitate and spinal animals but in the latter the tibial sometimes gave extension responses and the saphenous flexion. In the decerebrate preparations, rapid faradic stimulation sometimes showed flexor participation in the response while slower stimulation of the same strength gave crossed extension alone. This frequency reversal was not seen in decapitate and only once in spinal animals.—*Authors' conclusions.*

10063. **HOU, C. L., und E. TH. BRÜCKE. Reizversuche an Vorticellen. (Alles-oder-nichts-Gesetz, Dekrement der Erregungsleitung in der Narkose, Chronaxie.)** *Pflüger's Arch. Ges. Physiol.* 226(3): 411-417. 1 fig. 1930.—The response of the stalk muscle of *Vorticella* to stimulation by condenser discharges has been investigated. The authors conclude that the myonomes or contractile elements of healthy uninjured specimens obey the all-or-none law. Under anesthesia, as in a solution of 1.5% urethane, there is a decrease in the tonus of the stalk, a conduction of excitation with decrement and a variation

in the magnitude of excitation with the strength of the stimulus. Values for the chronaxie of a number of forms are given.—*D. W. Bronk.*

10064. HOU, CHUNG LIEN. Über die Veränderungen der Reizzeit-Spannungs-Kurve durch Narkose, Kälte und Veratrin. *Pflüger's Arch. Ges. Physiol.* 226(4/5): 676-688. 5 fig. 1931.—The first experiments were performed with the same pendulum as used by Kodera (Pflüger 219 & 220), and the curves showed the same large number of kinks. This was found to be due to a faulty closing contact, which when rectified gave smooth curves. For the rest of the work condenser discharges were used, the discharge rates being converted to seconds by Lapicque's factor .37 CR which was verified. The observations of former workers were confirmed as to the effect of narcotics (urethane and piscain) and temperature alteration. The changes are reversible, a rise in rheobase and shortening of chronaxie being produced by the action of narcotic or rise of temperature. Kodera and Brücke are confirmed in that veratrine poisoning of the curarised gastrocnemius gives rise to two quite different strength duration curves from direct excitation depending upon whether the twitch or contracture is taken as index of efficacy of stimulus. The chronaxie of the latter is 20 times as long as that of the former, and the thresholds are considerably higher.—*W. A. H. Rushton.*

10065. JACOBSON, EDMUND. Electrical measurements of neuromuscular states during mental activities. I. Imagination of movement involving skeletal muscle. *Amer. Jour. Physiol.* 91(2): 567-608. 2 fig. 1930.—The present conclusions relate to a simple act of imagined flexion of the forearm frequently repeated to secure statistics of measurements. (1) When the subject, lying relaxed with eyes closed, imagined that he was steadily bending his right forearm, action potentials were led off from a suitable electrode placed over the right biceps, with a 2nd electrode at a relatively indifferent point on the right arm. (2) No such potentials were recorded under the same conditions, including the same signal sounds, when the subject continued to relax and did not engage in imagination. Likewise the results were negative when the subject engaged in imagining that he was performing acts with other parts of his body, such as bending the left foot or bending the left arm, or when he actually bent the left foot or the left arm very slightly. The records secured during imagination are identical in type with records secured when the subject has been instructed to make slight actual muscular contraction, excepting only that the microvoltage is considerably less in the former instances. It is therefore concluded that the total physiological activity present when there is imagination of voluntary movement includes neuromuscular processes in the locale comprised in the imaginary act. A method of objectively measuring these neuromuscular processes is presented, and the possibility of the development of a branch of study analogous to physical chemistry, which may appropriately be called physical psychology, is herewith opened. The action potentials that occur during imagination of motion are very different from the psychogalvanic reflex. Relaxation of the neuromuscular processes characteristic of the occurrence of mental activities is generally accomplished within 1.5 sec. in the present experiments, when the motor imagination disappears. This is a confirmatory instance of the previous finding that diminution of mental activities can be brought about by muscular relaxation.—*Author's summary.*

10066. JACOBSON, EDMUND. Electrical measurements of neuromuscular states during mental activities. III. Visual imagination and recollection. IV. Evidence of contraction of specific muscles during imagination. *Amer. Jour. Physiol.* 95(3): 694-702; 703-712. 1930.—III. Electrical records can be secured characteristic respectively of looking to the right, left, up and down. These can generally be distinguished from frowning, winking, and convergence. During visual imagination and recollection electrical records are secured from the ocular muscles, producing photographic patterns like those following instructions to look in directions specified. As shown by these records, eye-movements characteristically occur during visual imagination and recollection. When the trained subject is requested to relax his eye-muscles, the curve becomes relatively horizontal and straight, characteristic of relaxation, and the visual imagination or recollection disappears, according to his report. Likewise, during control periods, when the subject has been instructed to keep his eye-muscles relaxed, he reports the absence of visual imagination or recollection. Reaction and relaxation times, except for minor differences, tally for tests following the instruction to imagine or recollect as compared with the instruction to look in a particular direction.—IV. Contraction of specific muscles takes place following the instruction to imagine an act performed with the voluntary musculature. The movement usually is of microscopic extent and generally confined within the group of muscles whose contraction would be required for the actual performance of the voluntary act. Imagination of a particular act performed by some portion of the body fails to occur if at the same time the muscles of this portion are completely relaxed. This supports the view that the contraction of specific muscles is essential to the occurrence of at least certain mental activities. The conclusion drawn by previous investigators that action-potentials from muscles always are associated with actual contraction is here extended to include a range of extremely low voltages. Evidence is conclusive that the electrical records ($V_{2m}{}^{c}$) during imagination, recollection and other mental activities are not psychogalvanic reflex phenomena.—*Author's conclusions.*

10067. JACOBSON, EDMUND. Electrical measurements of neuromuscular states during mental activities. VII. Imagination, recollection and abstract thinking involving the speech musculature. *Amer. Jour. Physiol.* 97(1): 200-209. 1931.—Into the muscular tissues of 7 subjects (6 more or less trained to relax) pointed electrodes of fine platinum-iridium were inserted about 1-2 cm. deep at the test regions. The click of a telegraph key was the signal to the subject to engage in a mental activity previously agreed on; a 2nd click was the signal to relax. In 5 of the 7 subjects, when the electrodes were connected in the speech musculature, the string shadow was practically quiet during relaxation. But promptly after the signal was sounded to engage in mental activity, marked vibrations appeared, indicating action-potentials. Soon after the signal to relax the vibrations ceased, and the string returned to rest. The series of vibrations during the mental activity occurred in patterns evidently corresponding with those present during actual speech. During the period of imagination, there occasionally appeared 1 or more series of action-potentials approximately equal in microvoltage to those which appeared during muscular movements visible to the naked eye. On the evidence previously considered, it is assumed that action-potentials in electrodes connected in muscle tissues signify the occurrence of contraction of fibers. The author concludes that while the muscular contractions occurring as a specific part of the physiologic process during imagination are generally microscopic, they are at times grossly visible.

10068. JOHNSON, H. M., and T. H. SWAN. Sleep. *Psychol. Bull.* 27(1): 1-39. 1930.—In this review the authors offer a searching analysis of (1) attempts to determine the depth of sleep by one type of sensory stimulation (papers by Kohlschütter, Mönninghof and Piesbergen, Michelson, Czerny, de Sanctis Neyroz); (2) studies of rest and activity based on registration of changes in bodily position (papers by Szymansky, Karger, Kreidl and Herz, Guttmann, Van Leeuwen); (3) measurements of O consumption upon awakening from sleep of variable duration (paper by Laird and Wheeler); (4) histological changes in the nervous system resulting from prolonged wakefulness (papers by Bast et al.); and (5) miscellaneous papers not falling

into the above classifications. These criticisms should be of interest to all students of the physiology of sleep.—*N. Kleitman.*

10069. KATO, G., T. HAYASHI, T. OTA, M. NAKAYAMA, H. TUMURA, M. TAKEUCHI, K. KANAI, and S. MATSUYAMA. Explanation of Wedensky inhibition. I. II. Explanation of "paradoxes Stadium" in the sense of Wedensky. *Amer. Jour. Physiol.* 89(2): 471-481. 6 fig.; (3): 692-714. 11 fig. 1929.—I. Six kinds of experiments were made to determine the point in the narcotized nerve at which the series of subnormal impulses vanishes. All gave the same result, viz., that the subnormal impulses are extinguished, not by decrement as supposed by Lucas, but at the beginning of the narcotized area, about 3-5 mm. inside the upper wall of the narcotizing chamber.—II. It was shown that the recovery curve of the narcotized part approached, as narcosis deepened, a horizontal line, indicating prolonged absolute refractory period and heightened threshold in the relative refractory period. To know the depth of narcosis necessary to produce complete inhibition, the least intervals were determined at A (normal part outside) as well as at B (narcotized part) through the whole course of narcosis. In the early stage of narcosis the least interval at A increased more slowly than that at B, and from certain stages the former increased more rapidly and overtook the latter. Therefore the curves A and B cross. Complete inhibition could never be produced until this stage of narcosis at which the curves cross, however frequent the tetanic stimuli might be. Curves A and B cross because the 2nd impulse started from A vanishes in the narcotized area by falling into the relative refractory period left by the 1st impulse. For the production of complete inhibition such a depth of narcosis is necessary that the 2nd impulse shall be extinguished on account of the heightened threshold in the relative refractory period due to the 1st impulse. This 2nd impulse, although itself extinguished, leaves behind an "after-effect" which lasts long enough to inhibit the 3rd, and so on. The duration of the inhibitory "after-effect" left by the 2nd (extinguished) impulse was measured. Similar experiments were made to measure the inhibitory "after-effect" left by the 3rd (extinguished) impulse. Furthermore, experiments are described in which the narcotized part was directly stimulated during the relative refractory period, with a stimulus which was below the threshold at the moment. The inhibitory "after-effect" left by such an apparently ineffective stimulus falling actually in the relative refractory period was measured. It was sufficiently long, in an advanced stage of narcosis, to account for the "after-effect" left by the extinguished impulse. The conditions necessary to produce complete inhibition are that curves A and B cross and that the 2nd impulse falls in the shaded area between AA and BB.—*From authors' summaries.*

10070. KING, C. E., E. A. BLAIR, and W. E. GARREY. The inspiratory augmentation of proprioceptive reflexes: a study of the knee jerk and the Achilles reflex. *Amer. Jour. Physiol.* 97(2): 329-342. 1931.—Experiments on men, dogs and cats demonstrate that with each inspiration in normal breathing the knee jerk and the Achilles reflex are augmented. The augmentation is not demonstrable in all subjects and animals, nor in the same ones at all times. The conditions, favorable and unfavorable, are discussed. The phenomenon is not a reflex from the respiratory tract or muscles, but is dependent upon the discharge of impulses from the respiratory center. There is no increase in the knee jerk during normal expiration, but during forced breathing there is some evidence of a slight increase. By forcing the respiratory effort the effects of inspiration are increased. The inspiratory augmentation is demonstrable through the whole range of intensity of stimulation, from threshold to maximal, but is best shown in the weak and medium range. Within the limits tested, the augmentation bears no relation to the rate of stimulation. The existence of a true refractory state is not essential for its production. The inspiratory augmentation of the reflexes studied is attributed to the irradiation of impulses from the respiratory center. The exact mechanism involved is not clear, but the possibilities have been stated, and the lines of work necessary for further clarification pointed out.—*Authors' summary.*

10071. KLINKE, J. Modelversuche zu einer capillarelektrischen Erregungstheorie. *Pflüger's Arch. Ges. Physiol.* 227(1/2): 110-131. 11 fig. 1931.—Changes in ionic concentration at phase boundaries in electrolytes, due to the passage of a current, were studied. The current was passed through strips of gelatine or collodion, either in air or immersed in an electrolytic solution, and the changes in concentrations of H and Cl ions observed. As was to be expected, these changes occur most where the current across the phase boundary is densest, and secondary anodes and cathodes may arise. The bearing of these results upon nerve and muscle excitation is considered.—*W. A. H. Rushton.*

10072. KNOWLTON, F. P., and C. J. CAMPBELL. Observations on peripheral inhibition in arthropods. *Amer. Jour. Physiol.* 91(1): 19-26. 1929.—In vertebrates all inhibition of skeletal muscle has its seat of action in the central nervous system. Therefore the study of inhibition is complicated by the intricacy of central nervous organization. In certain invertebrates the conditions are simpler. Stimulation of the claw of the crayfish has been shown to cause opening or closing, depending on the strength of stimulus applied, the phenomenon involving a reciprocal inhibition. The authors studied this type of inhibition on the lobster (*Homarus*), the blue crab (*Callinectis*) and the spider crab (*Libinia*). It does not appear to have been previously recognized that the selective excitability and reciprocal inhibition is not limited to the claw muscles but is general in the appendages of arthropods. At least as far as the authors have examined, the various joints which are moved by antagonistic flexor and extensor muscles may each be flexed or extended depending on the character of the stimulus. Peripherally produced summation, rhythm, delay, arrest, reversal and alternation, rebound and after-contraction, are described. Superficially, at least, these resemble similar phenomena associated with central conduction in vertebrates.

10073. KRAUS, WALTER M. The hypothalamus: a segmental structure and a regulator of glandular activity and metabolism. *Arch. Neurol. and Psych.* 25(4): 824-828. 2 fig. 1931.—The theory here advanced is that as the pituitary gland was originally a gland of external secretion that emptied its secretions into the alimentary canal and has developed into a gland of internal secretion, and as it regulates all metabolic processes rather than any single metabolic process, the most cephalic end of the segmental nervous system which controls the pituitary is an extremely primitive and altered segment of the central nervous system regulating metabolism in general. The remaining glands having fewer functions are regulated by the less cephalad segments of the central nervous system. The hypothalamus thus regarded is the guiding segment of that part of the segmental central nervous system which is concerned with visceral functions.

10074. KUBIE, LAWRENCE S. A theoretical application to some neurological problems of the properties of excitation waves which move in closed circuits. *Brain* 53(2): 166-177. 6 fig. 1930.—The hypothesis is offered that the brain is composed of 2 types of tissue, the "active" (consisting of neurone systems so intimately and directly related to the rest of the body that passage of an impulse along any of them always registers in some way in the body economy) and the "silent" (consisting of tissues through which impulses may circulate indefinitely without any external registration of their passage). Under normal conditions impulses impinge upon the active system only or chiefly from stimuli arising without the central nervous system. Abnormal (pathological) conditions may divert into active channels ordinarily impotent impulses, normally

circling through silent pathways, thereby causing spontaneous movement (chorea, athetosis, epilepsy, etc.), sensation or vegetative alteration. These speculations imply modification but not necessarily abandonment of the neurone theory: (a) Not all neurones must necessarily be organized for through-and-through conduction, with irreversible synapses. Those of the silent system may be organized for more circuitous and diffuse conduction systems. (b) Even within the active system it is conceivable that conduction in closed circuits may play some normal rôle—and certainly it must be reckoned with as one of the possible explanations of abnormal functions. (c) The excitation wave in dendrite and neurone may not be identical with the axonal impulse, as is usually assumed. The laws of conduction within the neurones of the central nervous system must, therefore, be studied as intensively as has been done in the peripheral axone. (d) The circling excitation wave may be closely related to the excitatory agent which Sherrington has found it necessary to postulate, and inhibition may find its mechanism, as Keith Lucas suggested, in some expression of the refractory phase; to which the suggestion is added here that it may be of the refractory phase, or some other fundamental attribute, of the circling excitation wave.

Gén.* 29(1): 72-76. 3 fig. 1931.—The excitability of a neuro-muscular preparation is inversely proportional to the chronaxie for a given value of the rheobase, and inversely proportional to the cube of the rheobase for a given value of the chronaxie.—*W. R. Fearon.*

10076. LANGWORTHY, ORTHELLO R., and CURT P. RICHTER. The influence of efferent cerebral pathways upon the sympathetic nervous system. *Brain* 53 (2): 178-193. 4 fig. 1930.—Using the galvanic skin response as a measure of sweat-gland activity, the controlling influences from the cortex, brain-stem and spinal cord were investigated [in 36 cats, first etherized and later decerebrated]. Definite galvanic skin responses were obtained from faradic stimulation of 2 areas adjacent to the motor cortex, from the floor of the 3rd ventricle, from the cortico-spinal and rubro-spinal tracts, from the vestibular nuclei, from the posterior column nuclei and from the posterior columns of the cervical cord. It is concluded that the same cerebro-efferent pathways which influence somatic motor cells also control preganglionic sympathetic cells; this cerebral control is predominantly an inhibitory one. Any cerebral centres influencing lower centres seem to exert final control through well-known cerebro-efferent pathways.—*Authors' summary.*

10078. LEARMONTH, JAMES R., and J. MARKOWITZ. Studies on the function of the lumbar sympathetic outflow. I. The relation of the lumbar sympathetic outflow to the sphincter ani internus. *Amer. Jour. Physiol.* 89(3): 686-691. 1929.—The sphincter derives a certain amt. of motor innervation through the lumbar sympathetic outflow. The majority of the fibers concerned are postganglionic fibers arising in the inferior mesenteric ganglion. A few motor fibers are not interrupted in the inferior mesenteric ganglion. Inhibitory fibers from the lumbar sympathetic outflow pass to the sphincter by way of the hypogastric nerves.—*Authors' summary and conclusions.*

10079. LINDBERG, ALEXANDER. Über die Wirkung von Lecithin auf die Grosshirnrinde. I. Einfluss chronischer subkutaner Einverleibungen von Lecithin auf die höchste Nerventätigkeit. *Jour. Psychol. u. Neurol.* 42 (5/6): 465-476. 1931.—A dog with left parotid gland fistula was subjected to various stimuli for 2 yrs.; and after reaction time to the conditioned reflexes had been determined 2 cc. of 1% emulsion of egg lecithin was injected daily subcutaneously. The lecithin increased the response to stimuli. Increased irritability of the central nervous system was not observed; instead, the central nervous system was strengthened, its resistance increased, in the shift from "stimulatory weakness" to normal activity.

10080. LULLIES, HANS. Über die Polarisation in Geweben. II. Die Polarisation im Nerven I. III. Die Polarisation im Nerven II. *Pflüger's Arch. Ges. Physiol.* 225(1): 69-86. 7 fig.; 87-97. 4 fig. 1930.—II. The resistance and polarization magnitude of the frog's nerve were measured with alternating currents of varying frequencies (30-300,000 d. v.). In relationship to these functions the nerve behaves like a polarization magnitude c with an unpolarized short-circuit w_1 in a series containing an additional resistance w. The polarizable layers consist of two parts, one of which has the character of non-reversible, the other of reversible electrodes. Measurements at different points along the course of the same nerve show that the polarization magnitude and the increase in resistance do not depend upon distance, which means that they are chiefly centralized at the point of entrance. The polarization begins in the outermost layers of the nerve but is not restricted to them as is shown by the relationship between the magnitude and the short circuit w_1. The effects of unpolarized short-circuits along the course of the nerve can be detected at very short distances, especially with low frequencies. III. In the determination of the resistance of the sciatic nerve of the frog to alternating currents of different frequencies it is found that both the effective and the unknown resistances are decreased as the measuring currents begin to exceed the threshold values. The amount of this decrease with currents of different strength, depends upon the intensity of the negative fluctuation of the residual current in the nerve itself. The effect diminishes with increased frequency and at 500 d. v. it cannot be demonstrated any more, probably because of fatigue phenomena. This effect is probably due to processes that occur at the stimulation of the nerve and that are accompanied by a decrease in polarization. Both effective and unknown resistance of this nerve contained in a moist chamber will decrease in the course of time. These changes were followed for several days and a graphic presentation of the relationship of this decrease to frequency and time is included. After 4-24 hrs. at room temp., the original polarization of the nerve practically disappeared and the irritability was extinguished. The high frequency resistances behave somewhat differently. After a period of time a new increase of resistance can be demonstrated. It is not dependent upon the frequency and shows no change of polarization.—*Author's summaries (transl. by W. Malamud).*

10081. LYONS, L. VOSBURGH, and RICHARD M. BRICKNER. Physiologic differences between generic and individually acquired automatic associated movements. *Arch. Neurol. and Psych.* 25(5): 998-1002. 4 fig. 1931.—Observation of a patient with typical epidemic encephalitis, presenting an extreme picture of parkinsonism, who still retained the ability to catch and throw a ball with a grace and ease acquired during a previous career as a star pitcher, suggests that, while phylogenetically associated automatic movements are seriously impaired in Parkinson's syndrome, there is a group of individually acquired automatic associated movements that may escape. This is added evidence that both groups depend on some type of anatomic patterning. Therefore, the rigidity alone cannot account for the impairment of movement in parkinsonism, which tends to show that the patterning of phylogenetic automatic associated movements is a striatal function. The patterning of the individually acquired movements is presumably a function of some part of the cortex.

10082. MACGREGOR, R. G., and S. PEAT. An investigation into a possible nervous mechanism involved in the liberation of histamime. *Jour. Physiol.* 71(1): 31-35. 1931.—In an investigation on 18 cats and 1 dog

into the reason for the relatively large amount of histamine in extracts of lung tissue, the authors removed the left lung of each animal as a control, subjected the right lung to the required experimental conditions, then removed the right lung, worked up both lungs by the method of Best, Dale, Dudley, and Thorpe to determine the amount of histamine present per unit weight of lung tissue, and compared the quantities in the 2 lungs. The method used determined the histamine content with not more than 20% error. Neither direct faradic stimulation of the nerves supplying the lungs (in 10 cats) nor perfusion with adrenalin, pilocarpin or physostigmin produced any detectable change in their histamine content.

10083. McSWINEY, B. A., and J. M. ROBSON. The sympathetic innervation of the stomach. II. The effect of stimulation of the peri-arterial nerves on the stomach and small intestine. *Jour. Physiol.* 71(2): 194-200. 1931.—Isolated strips of the smooth muscle of the stomach and small intestine innervated by peri-arterial nerves were prepared. The reaction of the gastric muscle depended on the type of stimulation employed. Stimulation of the nerves with frequencies of 1-12 break induction shocks per sec. caused contraction of the muscle; with 20-50 shocks per sec. relaxation was obtained. Reversal effects were also recorded by varying either the strength of current or the duration of faradic stimulation. The motor response was abolished by addition of ergotoxine or atropine. The movements of the intestine were inhibited by all types of stimulation. The latent periods of contraction and relaxation were recorded and compared with the latent periods obtained on stimulation of the vagus nerve. Evidence is put forward to show that the motor and inhibitor response is due to stimulation of sympathetic fibers conveyed in the peri-arterial nervous network.—*Authors' summary.*

10084. MANSON, J. S., and FERGUS R. FERGUSON. "Decerebrate rigidity" in man. *Brit. Med. Jour.* 2(3644): 769-771. 1930.—A clinical case is described in which the patient lay motionless and speechless during the greater part of 10 yrs., with his arms adducted and flexed at the elbows and wrists, and his legs rigidly extended—in the position regarded by Walshe and others as the physiological counterpart of experimental decerebrate rigidity. At necropsy a firm, rounded, apparently endotheliomatous subdural tumor about 2 inches in diameter was found in the right pre-Rolandic area growing from the falx cerebri.

10085. MARINESCO, G., et A. KREINDLER. Les réflexes du sinus carotidien en pathologie nerveuse. *Jour. Physiol. et Path. Gén.* 29(1): 77-92. 10 fig. 1931.—In addition to the 3 recognized carotid-reflexes (cardiac inhibitory, respiratory, vaso-motor), a 4th is reported, and is shown by a fall in the level of the plethysmograph-curve during compression of the carotid sinus. In epilepsy the carotid reflex is diminished, thus accounting for vaso-motor instability accompanying the disease. Compression of the carotid sinus is effective in controlling the convulsions in some cases of epilepsy and encephalitis. Phenylethyl-malonyl-urea sensitizes the sinus, which may explain the beneficial action of the drug in epilepsy. The respiratory carotid-reflex is altered in Parkinsonian encephalitis, and the vaso-motor reflex is diminished in myasthenia and in adrenal insufficiency.—*W. R. Fearon.*

10086. MATTHEWS, BRYAN H. C. The response of a single end organ. *Jour. Physiol.* 71(1): 64-110. 2 pl. 1931.—A method is described of making a muscle preparation containing a single nerve ending (lying in the centre of the muscle, where histological preparations reveal a single muscle spindle) responding to stretch. The response is recorded with a moving iron oscillograph and is found to be extremely constant for any given tension. If the muscle is kept in a small quantity of Ringer for some time the response in the nerve is first depressed and then disappears, but returns to its initial magnitude when the Ringer is changed. Frequency of response is roughly proportional to the logarithm of the load. When the muscle is loaded rapidly the interval between the impulses set up is little greater than the absolute refractory period of the nerve fibers concerned, and the time relations of the action currents of these impulses are modified, showing that they are travelling in an incompletely recovered nerve fibre. It seems possible that these rapid discharges may be due to continuous rather than intermittent excitation of the nerve fiber. The viscosity of the end organ may account for the discontinuities in the response when small loads are applied rapidly. The interval between the impulses at the highest frequency recorded varies with temp. in much the same way as does the refractory period of a nerve trunk. Behavior of the end organ is greatly modified by the ionic composition of the surrounding fluid. In NaCl frequency of discharge remains high for some min.; addition of either Ca or K alone reduces the response below that obtained in Ringer, Ca and K appearing to have an antagonistic action. Rhythmic discharge of grouped impulses occurs when the preparation is kept at 25° in NaCl: the response can be modified by passing a steady current through the muscle, change in response depending on the direction of current flow. HCN causes a transient increase in the response later followed by extinction of the discharge. Adaptation is examined, and it is found that there is an after effect lasting several sec. after the stimulus is removed. This adaptation remainder has been measured quantitatively and is found to develop as stimulation is prolonged and vanish in a few sec. after the stimulus is removed. The adaptation remainder is found to be a function of the total stimulation, i.e., the magnitude of the load and the time it has been acting. A hypothesis is suggested to account for the observed behavior of these end organs.—*From author's summary.*

Neurol. and Psych.* 25(5): 986-997. 5 fig. 1931.—Severe pain was relieved by interruption of the dorsal sympathetic fibers in 31 cases, suggesting that there may be definite sensory fibers running in the dorsal sympathetic chain.

10088. MONTGOMERY, MARY F., and ARNO B. LUCKHARDT. Studies on the knee jerk. VIII. The effects of acutely raised intracranial and intraspinal pressures upon the knee jerk. *Amer. Jour. Physiol.* 91 (1): 210-219. 1929.—Of 17 dogs used, 15 produced useful records. The intracranial pressure was raised a total of 132 times, the intraspinal pressure 31 times, on these animals. Increasing the intracranial pressure to a point where it approaches the carotid arterial blood pressure leads to a fairly abrupt diminution in the height or abolition of the knee jerk preceded in some instances by a few jerks of increased amplitude. If the cord has been cut above the knee jerk center, the knee jerk is not affected until the respiratory and vasomotor centers have been paralyzed. The abolition of the knee jerk then seen is due to asphyxia of the center, and perhaps also to inadequate circulation through the center. Increase in the intraspinal pressure following transection of the cord above the knee jerk center, results in a temporary but marked increase in the amplitude of the knee jerk, followed by a complete abolition of the reflex. These results are attributed to cessation of the blood flow through the cord (asphyxia), for ligation of the abdominal aorta in the upper lumbar region gives similar results.

10089. MOSER, KURT. Zur Frage eines zentral-vegetativen Blutregulationszentrums. *Deutsche Med. Wochenschr.* 56(29): 1209-1211. 1930.—In about 30 cases of encephalitic Parkinsonism leukocyte values on the upper normal level were strikingly frequent and in part a distinct hyperleukocytosis; similar values were seen in 4 cases of arteriosclerosis with paralysis agitans and in 3 tumors of the region of the brain stalk, all pointing to the existence of G. Rosenow's vegetative blood-regulating center.

10090. MUSSEN, AUBREY T. The cerebellum: the

influence of the cortical reactions on the classification and the homology of the lobes and fissures in the cat, monkey and man. *Arch. Neurol. and Psychiatr.* 24(5): 913-920. 1930.—After discussing the confused nomenclature and the homology of the cerebellar lobes in man, the cat and the monkey, Mussen proposes a new classification of these lobes, equally applicable to all 3 animals, based on the reactions of the individual lobes to stimulation. The idea, he admits, is contrary to the views of most leading authorities; the method of investigation on which he bases his classification has never before been tried in the same precise manner: the experiments of Horsley and Clarke, which are largely responsible for the view that the cerebellar cortex was inexcitable, were not entirely negative, for they also reported movements in the head, eyes and extremities, though not localized. In many instances the reactions to stimulation are entirely supported by operative results and developmental conditions. After several years of experimentation on the cerebellum, the reason why so many investigations have proved fruitless is fairly clear. The usual method of free exposure for either stimulation or destruction may be accompanied by severe hemorrhage which lowers its activity and greatly weakens the animal; precautions against hemorrhage by the temporary constriction of the vessels are not satisfactory, for they reduce the excitability of the cortex; this manner of operating cannot be recommended. Another obvious cause for the absence of localizing symptoms in experimental lesions is the fact that in almost every instance the destruction of tissue has been far too extensive, involving lobes of different functions and producing results that were naturally confused.

10091. MUSSEN, AUBREY T. The cerebellum: comparison of symptoms resulting from lesions of individual lobes with reactions of the same lobes to stimulation: a preliminary report. *Arch. Neurol. and Psychiatr.* 25(4): 702-722. 10 fig. 1931.—The author previously offered evidence that the cortex of the individual lobes of the cerebellum showed localized reactions. As conclusive proof he has now undertaken localized destruction of individual lobes in cats. Results indicate that the interior vermis is definitely associated with the maintenance of forward balance, the posterior vermis with backward balance, and the middle lobe of the vermis with rotation movements of the head. The loss of forward balance from a lesion in the anterior vermis, the loss of backward balance from a lesion in the posterior vermis and the rotation of the head to the opposite side when ½ of the middle lobe of the vermis was injured have shown that the vermis is divided into 3 lobes each with a distinctive function; the same 3 divisions also apply to the hemispheres and consequently to the cerebellum as a whole. The function of the individual lobes, as indicated by the stimulation experiments, does not mean that the lobe is concerned only with that particular activity, but suggests that the lobe is responsible for whatever coordination is necessary to assure the proper performance of the act with which it is especially associated; e.g., the anterior lobe of the vermis gives reactions in the posterior muscles of the neck, the principal function of which is the maintenance of forward balance. When forward balance is disturbed this function is called into action and the first evidence of cerebellar activity is the posterior neck reflex, which provides for the necessary readjustment to take care of the threatened loss of equilibrium. This indicates that cerebellar activity may be considered to be composed of 2 distinct reactions: (1) the primary reflex, the nature of which depends on the particular lobe involved, and (2) the secondary response, which integrates the synergic activity set in motion by the primary reflex. The normal cerebellum always acts as a whole.

10092. NEMOTO, MAMORU, and HIROSHI SATO. Über die Folge der Erwärmung des Karotidenblutes auf die Atmung beim Kaninchen, dem das Corpus striatum entfernt oder der Kältestich ausgeführt ist. *Tohoku Jour. Exp. Med.* 14(2/3): 109-134. 8 fig. 1929.—When blood of animals thus treated was warmed tachypnea appeared although usually (but not always) in less marked degree than in normal animals. This result thus fails to confirm the view that the higher brain centers take part in producing tachypnea whenever the blood undergoes a rise of temperature.—*C. D. Snyder.*

10093. NEMOTO, MAMORU. Sur la relation du temps écoulé entre les premières mises en action des excitants conditionnels et non-conditionnels combinés pour développer le réflexe conditionnel. *Tohoku Jour. Exp. Med.* 14(5/6): 466-486. 1930.—From experiments on dogs it is concluded that in order to develop a conditional reflex, the conditioned stimulus must precede the unconditioned by some seconds, e.g., 5 to 10 sec. This time, preceding the conditioned reflex, will perhaps vary somewhat with the individuality of the subject.—*C. D. Snyder.*

10094. PAGE, IRVINE H., und WILH. MENSCHICK. Über das Vorkommen von Ergosterin im menschlichen Gehirn. [Ergosterol in the human brain.] *Biochem. Zeitschr.* 231(4/6): 446-459. 1931.—The absorption spectra of purified sterol fractions from fetal, newborn, infant, and adult brains appeared in the 1st 3 absorption maxima at 294, 283, and 250 mμ. The maxima 294 and 283 mμ belong to ergosterol, which decreases from 0.05% in the fetus to 0.01% in the child of 1½ yrs. The band at 250 mμ is entirely unaccounted for. The absolute amt. of ergosterol reaches its maximum of less than 1 mgm. before the end of the 1st yr., decreasing considerably thereafter.

[Statement of priority: The somatic factors of sensation and representation and generally of intellectual activity.] *Boll. Soc. Ital. Biol. Sperim.* 5(3): 359-361. 1930.—In 1912 Patrizi had studied, with the plethysmograph, the somatic factors of the sensation and representation, and further the object of the autoscopic attention and the localisation of its motor expression. The studies of Patrizi on the somatic factors of intellectual activity are prior to those of Jacobson (Chicago).—*M. Comel.*

10096. PORTER, EUGENE L. Evidence that the postural tonus of decerebrate rigidity increases in amount by the successive innervation of single motor neurones. *Amer. Jour. Physiol.* 91(1): 345-361. 1 fig. 1929.—A method is described by which a small muscle in the tail is used in the study of postural tonus in the decerebrate cat. With this as a nerve muscle preparation gradually increasing single shocks are applied to the motor-nerve; the response of the muscle is by contraction occurring in steplike groups with no intermediate gradation. Each group step represents, presumably, the activity of a single motor neurone and the muscle fibers innervated by it. Tonic contraction may be induced or increased in the tail muscle by various measures which are described, or it may occur spontaneously. By whatever means produced the increase in contraction height is never smooth and uniform but always by sharp steps. The steplike increments in tonic contraction height are approximately the same size as the steps in a nerve-muscle record from the same muscle. The inference is drawn that in producing an increase in postural tonus the central nervous system throws into action one motor neurone after another. The all-or-none contraction of all muscle fibers innervated by each neurone produces the steplike increase in contraction height. In certain records when the tonus is spontaneous and self-perpetuated, steps may be seen to drop out from the record and reappear again while the general level of contraction remains fairly constant. This is taken as evidence of rotation of activity of single neuromuscular units of contraction. This supports the theory that the apparent lack of fatigue in postural tonus depends on such rotational activity (Forbes, 1922). The fact that steps of an all-or-none character corresponding in size to nerve-muscle steps may be demonstrated both in the

spinal flexion reflex and in postural tonic contraction is regarded as favoring the view that the same mechanism on the motor-side is operative in both cases.—*Author's summary.*

10097. POSNANSKAJA, INNA B., und W. W. EFIMOFF. Der Einfluss der geistigen Ermüdung auf die bedingt reflektorische Tätigkeit des Menschen. *Arbeitsphysiologie* 3(6): 456-467. 2 fig. 1930.—The experiments were carried out in a divided room in one part of which the experimenter operated the various combinations and recorded the results while in the other part the subject sat and responded to the various combinations by pressing a small rubber ball. Seven different kinds of combinations were used, conditioned reflex to a 75 c.p. white lamp, to a synthetic sound signal of 4 tones, synthetic light signal of 4 colors, inhibition to differentiated synthetic sound signal, inhibition to differentiated synthetic light signal, simple conditioned sound inhibition of reflex to the synthetic light signal, and a delayed reflex to a sound signal. The 35 subjects were first put through a practice period of several days to have the conditioned reflexes and inhibitions thoroughly established. They then went through the procedures as usual on a given day and then went into an adjoining room and hung tegs, marking each one, upon a circular conveyor for 1 hour. The subjects returned to the experimental room and the same order of reflexes were tested as before the work. Under the influence of fatigue a disturbance of the equilibrium of the inhibiting and excitation processes of the cortex resulted. The intensity of the change of the conditioned reflex activity due to the work was individually very different. In a number of the subjects no alterations took place, that is after one hour's uninterrupted work on a conveyor no indications of mental fatigue were observed. Three kinds of fatiguing influences were noted: a) the inhibiting, b) the stimulating, and c) a mixture of both. A certain relationship was found between the type of reaction of the individual and the influences of fatigue. The method of investigating the conditioned reflexes with men furnishes the approach to a professional physiological selection of persons with specially stable nervous systems difficult to fatigue for occupations more or less fatiguing to the nervous system. This requirement grows more pressing in the present extended mechanization of work.—*T. M. Carpenter.*

10098. PRITCHARD, E. A. BLAKE. Central mechanism of the reflex arc. A description of a ballistic model in terms of which to unify explanations of spinal reflex activity and certain changes in the voluntary electromyogram in man. *Brain* 53(4): 431-448. 2 fig. 1931.—The behavior of this model (representing the nervous mechanism discussed by the author (*Brain* 53(3): 344-375. 1930)) subjected to units of equal and opposing forces (representing the impulses supplied along an afferent nerve) agrees with the observed facts of spinal reflex activity. It is inferred that the suggested localization of the site of origin of the changes in the voluntary electromyogram is not inconsistent with the observed facts of spinal reflex activity.

10099. RENQVIST, Y., V. LESKINEN, und S. PARVIAINEN. Die Bedeutung des Parameters a der Weiss-Hoorwegschen Reizformel. *Skand. Arch. Physiol.* 61: 113. 1931.—The formula considered is $V = a/t + b$ where V is the voltage of the stimulating current, t its duration, b the rheobase, and a is the quantity of electricity (current $\times$ time) at the point where the graph of Vt as plotted against time cuts the ordinate. The rheobase b is the value of the asymptote parallel to the horizontal axis of the rectangular hyperbola formed when V is plotted against t for a liminal stimulus. The ratio a/b represents the chronaxie, when V is given double the rheobase value. Then $2b = a/t + b$ or $t = a/b$. Further, if the chronaxie is represented by τ, $a/b = \tau$, or $a = b\tau$; the product of the rheobase and the chronaxie is invariant. Experimentally, using different muscles of the hind leg of the frog, stimulated through the sciatic nerve, the authors find that the values of b and τ vary in different muscles. The product however is constant, so long as the same nerve supply is stimulated. The invariance of a is not found when the muscle fibers are stimulated directly or when the same muscle is stimulated by different nerves. It thus appears to have different values depending upon the groups of fibers stimulated, being smallest when the muscle is stimulated through its nerve. These findings are explained on the basis of a grouping of nerve fibers within the sciatic nerve which show the same effective capacity for stimulation notwithstanding the fact that they may innervate different muscles.—*J. A. E. Eyster.*

10100. SCHALTENBRAND, GEORGES, and STANLEY COBB. Clinical and anatomical studies on two cats without neocortex. *Brain* 53(4): 449-488. 23 fig. 1931.—Two cats without neocortex are described clinically and anatomically. In the 1st both cerebral hemispheres were removed anterior to the thalamus; this animal lived for 9 days after the 2nd operation. It exhibited states of waking and sleep, and when awake it made purposeless circus movements. It did not eat spontaneously. In the other animal the rhinencephalon and striatum were left intact; this animal was kept alive for 5 mos. after the 2nd operation. Immediately after the 2nd operation it showed much more activity and a greater variety of movements and of reactivity than the thalamus cat. It reached and ate its food spontaneously, and for a time it had polydypsia, polyphagia and polyuria, which were probably due to destruction of the right nucleus filiformis. Immediately after the operation the animal developed a well-marked shaking reflex of the extremities; this was shown to be an exaggeration of the normal shaking reflex which serves to clean or dry the paws. The animal cleaned its fur spontaneously. Its motor activity, when recorded in an "activity cage," was found to be much greater than that of a normal cat. This excessive activity was excited by noise, and increased during infection by nematodes and mange. Rotational nystagmus and after-nystagmus were studied on a rotating wheel, and were shown to follow the same rules as in intact animals and in man. As long as the speed and the amount of rotation were kept within physiological limits, the number of jerks depended chiefly on the degree of rotation. On longer rotation the after-nystagmus assumed the characters of a reaction to acceleration. Electrical stimulation, immediately before the animal was killed, of those portions of the brain which remained revealed 2 points which were definitely excitable. The 1st proved to be the anterior commissure; stimulation of this produced movements relating to smelling and eating, as puckering of the nose, licking, moving the whiskers and chewing. The 2nd point lay above a small comma-shaped nucleus in the velum medullare; stimulation of it gave rise to urination and changes in the respiratory rhythm. The anatomical examination showed that, on the whole, the aim of the operation had been attained; the few portions of the neocortex which had been left had no fibre connections with the brain-stem. The anterior and lateral parts of the thalami had undergone severe atrophy. This atrophy was more marked on the left side on which the striatum had been damaged.—*Authors' summary.*

10101. SCHMITT, FRANCIS O. On the nature of the nerve impulse. I. The effect of carbon monoxide on medullated nerve. *Amer. Jour. Physiol.* 95(3): 650-661. 1930.—For the study of the effect of CO on the O uptake of resting nerves the Warburg manometric technique was employed. The respiration of nerve is inhibited in the dark by CO-O mixtures. This inhibition may be fairly complete, the degree depending on the partial pressure of the CO and upon conditions of diffusion in the nerve. Light markedly decreases this inhibition, the decrease stopping when the illumination is discontinued. The maximum height of the action potential as measured by the cathode ray oscillograph is reduced in CO-O mixtures in the dark, and ultimately to zero, the time required for extinction depending on the partial pressure of the CO. Intense illumination of the nerve

during the period of the failure causes the height of the action potential to rise to, and in some cases to exceed somewhat the normal level. When illumination is discontinued, the action potential does not drop immediately to the original extinction curve, but does so gradually after a period of time. This period of after-effect of light is of fairly constant duration and usually lasts 25 to 30 min. These facts are interpreted to mean that the action potential whether aerobic or anaerobic requires an oxidation or oxygenation of substances in nerve and that activation of the O by a respiratory enzyme similar to that of Warburg is essential. The mechanism of this oxidation system is briefly discussed. —*Author's summary.*

10102. **SCHMITT, FRANCIS O., and OTTO H. A. SCHMITT. The nature of the nerve impulse. II. The effect of cyanides upon medullated nerves.** *Amer. Jour. Physiol.* 97(2): 302-314. 1931.—Experiments here summarized indicate that the O consumption of resting nerves of the green frog may be practically completely inhibited by cyanides, whether the nerve is suspended in Ringer solution or in phosphate or bicarbonate buffer, and whether the measurements are made under physiological CO_2 tension or at zero CO_2 tension. The action potential is abolished in N/100 NaCN about as rapidly as in pure N, i.e., in about 100 min. N/5000 NaCN is still capable of abolishing the action potential, although more dilute solutions act much more slowly and never completely block it. Cyanided nerves stained in methylene blue fail just as rapidly as do unstained cyanided nerves. The possible catalytic action of the dye is discussed.—*Authors' summary.*

10103. **SCHTSCHERBAKOW, S. A., W. S. SIMNITZKY, A. A. WISCHNEWSKY (Jun.), und W. R. DIMITRIJEW. Der Einfluss des Schmerzreizes auf die Nebennierensecretion und den Blutzucker.** *Pflüger's Arch. Ges. Physiol.* 224(5): 670-677. 4 fig. 1930.—The experiments were carried out on cats and dogs. It was found that the stimulation of the sciatic nerve with a faradic current caused an increase in the blood sugar. This occurred only when the adrenals were intact. When the adrenal veins were tied off, or when the splanchnic nerves were cut, the stimulations caused a decrease instead of an increase in blood sugar. Blood taken from the adrenal vein at the time of stimulation and injected into the veins of another animal caused an increase of the blood sugar in the latter. This means that a pain-stimulus excites an internal secretion reflex arc which reaches the adrenals by way of the splanchnic nerves and causes the production of a secretion which when released into the blood stream increases blood sugar.—*W. Malamud.*

10104. **SHARPEY-SCHAFER, E. The nomenclature of the autonomic nervous system.** *Jour. Physiol.* 71(4): 362-363. 1931.—In using the anatomical term "sympathetic" to express a particular nervous action we unintentionally include 2 antagonistic effects (excitation and inhibition). Physiological effects should be denoted by purely physiological terms, the anatomical terms being reserved for the fibers which convey the nervous impulse.

10105. **SHERRINGTON, C. S. Notes on the knee extensor and the mirror myograph.** *Jour. Physiol.* 70 (1): 101-107. 2 fig. 1930.—Stretch reflexes are recorded for knee and ankle extensors in the decerebrate frog. From observations on rectus femoris an estimate is outlined for the contraction tension of the extensors of knee and ankle (cat). The arrangement and construction of a myograph suitable for mammalian observations are described.—*Author's summary.*

10106. **STAVRAKY, GEORGE. The action of partly degenerated sympathetic nerve on the submaxillary gland in the dog.** *Trans. Roy. Soc. Canada, Sect. 5, Biol. Sci.* 24(1): 193-195. 1930.—The experiments reported "show that in the submaxillary gland of the dog there is some contractile tissue which is under the control of the sympathetic innervation, and which may be stimulated by histamine. The preganglionic nerve fibers to this contractile tissue are more stable than the vasoconstrictor and presumably the secretory sympathetic fibres. The augmented secretory effect obtained by stimulation of the partly degenerated sympathetic nerve is chiefly due to the presence of these motor fibres in the nerve."

10107. **STEIN, JOHN BETHUNE, and JOSEPH TULGAN. Reciprocal reaction in the cat as a possible local mechanism. III. The reciprocal reaction of the biceps brachii and the triceps brachii.** *Amer. Jour. Physiol.* 95(1): 174-177. 1930.—At the shoulder-joint of the cat there appears to be a nervous mechanism for the reciprocal reaction of the biceps and the triceps,—evidently local, because cutting the brachial plexus does not abolish the reciprocal reactions of the 2 muscles. The reciprocal reactions of the 2 muscles in this case could be reversed, i.e., no matter which of the 2 muscles in question was made the protagonist, its antagonist relaxed. Is this local mechanism a mediate agency in correlating the chronaxies of the protagonistic and antagonistic muscles?—*Authors' conclusions.*

Physiol.* 226(4/5): 600-658. 21 fig. 1931.—The author restates his resonance theory with a minor modification and cites a series of experiments involving transplantation of muscles in the toad with functioning connection with a selected peripheral nerve. The results are interpreted as evidence in support of his theory.—*G. P. McCouch.*

10109. **WENNER, W. W., and A. B. TAYLOR. The effect of changes in acid-base equilibrium on reflex time.** *Amer. Jour. Physiol.* 91(2): 365-369. 1930.—The patellar tendon reflex time of [6] normal unanesthetized dogs was determined and compared with the reflex time of the same dogs after administrations of NH_4Cl and $NaHCO_3$. From results obtained the authors believe that with an increase in H ion concentration there is a decrement created at the synapse or the motor end plates or perhaps both neural and neuro-muscular factors are involved. This would probably block out the higher cortical centers and thus shorten the reflex arc and thus account for the decreased reflex time. It would seem probable then that an increase in OH ions produces an effect opposite to that of H ions, that is, the decrement at the nerve endings would be decreased. If such is the case then the passage of the nerve impulse would be facilitated and the reflex time decreased. In this condition the reflex arc is not shortened.

10110. **WINDLE, WILLIAM FREDERICK. The relation of the level of transection of the brain-stem to the occurrence of decerebrate rigidity in young animals.** *Jour. Comp. Neurol.* 48(2): 227-245. 2 fig. 1929.—Decerebration was performed on cats and dogs, most of which varied in age from a few hours to several days after birth. In some cases the knife was passed through or just cephalad to the superior colliculi dorsally and through or just cephalad to the optic chiasma ventrally, leaving the hypothalamus and red nuclei intact. These animals retained the ability to right themselves and progress spontaneously by crawling. Alternate progressive movements could be elicited by mild stimuli (tactile), and the animals responded more vigorously than normal unoperated controls. Extensor rigidity was sometimes observed between periods of active progression. Other animals were decerebrated by passing the knife through the cephalic border of the superior colliculi and the cephalic border of the pons, thus removing the red nuclei. In these animals righting and progression responses were absent and decerebrate extensor rigidity appeared. The fore legs always showed marked hyperextension, while the hind legs, head, and tail varied somewhat in the degree of rigidity present. While unoperated animals did not voluntarily support their body weight upon their legs, it was not infrequently found that after decerebration at the low level they were able to do so. It is believed, therefore, that a mechanism

for the production of extensor hypertonus is present in the cat and dog at birth.—*Author (courtesy Wistar Bibl. Serv.)*.

10113. ARMSTRONG, PHILIP B. Functional reactions in the embryonic heart accompanying the ingrowth and development of the vagus innervation. *Jour. Exp. Zool.* 58(1): 43-67. 3 pl., 1 fig. 1930.—The embryonic *Fundulus* heart beats for several days before there is any physiological indication that vagus nerves have reached the heart. During this aneural stage the heart differentiates from a straight tube to essentially the adult condition. Vagus effects can be obtained only after this differentiation is finished. By mechanical methods the developing vagus nerves can be reflexly stimulated. If the embryo is left undisturbed, beat initiation and transmission are the same as in the aneural stage. The vagus responses only gradually involve the various parts of the heart, so that, including the aneural stage, there are 5 physiological stages in its development. The auricle, auricular-canal anlage and ventricle, and the sinus venosus are successively involved in the vagus response, and their functions are negatively affected. The vagus effects are abolished by atropin, a vagus depressant. The reestablishment of normal rhythm from the inhibited condition always takes place in the reverse order of its ontogenetic development. During the development of the physiological effects of the nerves on the heart there is no indication of transposition of automaticity and conductivity from the heart muscle to the cardiac nervous system. Throughout all stages beat initiation remains myogenic and beat conduction myodromic. The development of nervous responses in the heart is compared to the development of swimming reactions in *Amblystoma* as described by Coghill.—*Author (courtesy Wistar Bibl. Serv.)*.

10114. ASHMAN, RICHARD, and ROBERTA HAFKESBRING. Unidirectional block in heart muscle. *Amer. Jour. Physiol.* 91(1): 65-82. 5 fig. 1929.—By means of asymmetric pressure applied to the middle of a ventricular strip from the turtle heart, it is possible, in the greater number of cases, to produce irreciprocal conduction in the direction desired. An impulse passing from normal to a narrow region of strongly compressed muscle may pass on to a less strongly compressed region and thence into normal muscle. If the process is set up at the opposite end of the strip, so that it must traverse the less before reaching the more strongly compressed region, it may fail to pass the region of compression. Under similar conditions, before irreciprocal conduction appears, the impulse will usually traverse the strip more rapidly in the direction from stronger to weaker compression than the opposite.—*Authors' summary.*

10115. BARCROFT, H. Cardiac output and blood distribution. *Jour. Physiol.* 71(3): 280-291. 2 fig. 1931.—The systemic output of the heart has been measured in dogs [number not stated] with the mechanical stromuhr. Complete occlusion of the thoracic aorta increases the systemic output after section of the vagi. This is due to a transference of blood from the vessels supplied by the thoracic aorta to the remainder of the vascular system. Simultaneous occlusion of the thoracic aorta and inferior vena cava causes increase in the blood-pressure and in the flow through the brachiocephalic artery, due to the transference of a quantity of blood from the cardiopulmonary system to the remainder of the vascular system.—*Author's summary.*

10116. BECKMANN, RENATA. Die Wirkung der Wasserstoffionenkonzentration auf überlebende Venen. *Pflüger's Arch. Ges. Physiol.* 223(1/2): 561-581. 8 fig. 1929.—This article discusses the veins as a factor in the regulation of the volume output of the heart and especially the effects of changes in C_H on the contraction and dilatation of circular strips cut from 5 different veins of the ox. About 170 strips were placed in Ringer's solution (Fleisch formula) at 37° C. A decrease in pH from 7.4 to 7.3 was sufficient to cause contraction in specimens from vena saphena, cephalica and iliaca and a change from pH 7.3 to 7.4 resulted in relaxation; whereas strips from v. jugularis and mesenterica were comparatively uninfluenced. Not all specimens from any one region were equally affected. There was some relation between the intensity of reaction and amount of change in pH, and a latent period averaging 2½ to 5 min. was noted. The experiments did not locate the exact seat of the vasoconstrictor action nor decide whether in vivo it is the pH of circulating blood or of tissue fluids which is the main factor in this action, which must be important in the regulation of the heart's stroke volume. Epinephrine may be a factor in the sensitivity of the veins to pH increase. 39 references.—*M. Dresbach.*

du liquide nutritif. *Arch. Internat. Physiol.* 31(3): 272-309. 11 fig. 1929.—A balanced physiological saline increases the activity of fragments of chick embryo hearts more than the addition of chicken plasma. Slightly larger amounts of $CaCl_2$ and KCl further increase the activity of the fragments for about 2 hrs., but activity is actually lost sooner than in the controls. Isotonic solutions plus .1% KCl increase the contractility for 30 to 60 min. but standstill appears earlier than in the controls. Isotonic solutions plus .085, .1 and .125% $CaCl_2$ bring about a rapid but transitory increase in contractility. Hypotonic solutions also increase contractility of the fragments. Uranium acetate in .85% NaCl shows excitation if the concentration is .2% or lower. This salt dissolved in H_2O or hypotonic solutions produces depression rather than excitation. Culture of heart fragments in plasma and hypertonic solutions containing excess of $CaCl_2$ and KCl is difficult for the cell elements are reduced in volume and irregular in form. An excess of KCl does not stop migration or multiplication of cell elements but it does determine a vacuolisation of the cytoplasm. The fragments, however, may recover and be transplanted. The addition of $CaCl_2$ does not affect rate of growth or form of the myoblasts. Hypotonic solutions have no effect except an expansion of the cytoplasm. Uranium acetate prevents a culture from developing migration. If migration is in process then uranium brings about profound changes, such as the formation of vacuoles and fat droplets and nuclear changes which rapidly destroy the culture.—*W. J. Meek.*

10120. COPE, OTIS M. The effect of exercise on ventricular minute-output time. *Amer. Jour. Physiol.* 94(1): 140-143. 2 fig. 1930.—Carotid pulse tracings were taken from 8 individuals during work on a stationary bicycle. The effects of light and heavy exercise on the cycle length and minute output-time were thus recorded. It is shown that the heart adjusts itself to increased demands not only by increased rate but also by relative increase in its ejection phase, and that this adjustment takes place more rapidly and therefore more efficiently than the heart-rate changes when the work ceases.—*Author's summary.*

10121. CORUZZI, CESARE. Eccitazioni cutanee e pressione sanguigna. [Cutaneous stimulation and blood pressure.] *Clin. Med. Italiana* 61(1/2): 57-75. 1930.—Various means of cutaneous stimulation were used repeatedly on 3 subjects, by preference hypodermic injection of physiologic solution. Fall or rise of arterial pressure was observed according to the stimulated region, the most pronounced fall occurring after stimulation of the region corresponding to the projection of the heart on the thorax, and rise to the umbilical region. Later studies, in which physiologic solution was replaced by neurotropic substances, indicated that variations of arterial pressure in response to cutaneous stimulus (in particular, injection of various substances into the cellular tissue) are due to stimulation of the sympathetic nervous system in which the heart is involved through the thoracal cardiac nerves of sympathetic origin.—*From author's summary (transl.).*

10122. DANIELOPOLU, D., und I. MARCU. Reflexogene Zonen der Carotis. V. Respiratorischer Tonus des Sinus caroticus. *Zeitschr. Ges. Exp. Med.* 75(3/4): 347-352. 1931.—Experiments on dogs and cats showed that bilateral occlusion of the common carotid often produced changes in respiratory rhythm (increase or decrease) and increase in blood pressure. This was much more distinct after bilateral vagotomy. It was caused by suppression of the respiratory tonus in the carotid sinus; alterations in respiration from stimulation of the carotid sinus were caused by the sino-carotid reflex; these frequently succeeded the alteration due to occlusion of the carotid, the rush of blood acting as a stimulus. The change in rhythm was not due to cerebral anemia.

10123. DANIELOPOLU, D., I. MARCU, et G. G. PROCA. Inhibition cardiaque provoquée par la suppression fonctionelle du sinus carotidien après l'interception des filets sympathiques du coeur. *Compt. Rend. Soc. Biol.* 106(9): 731-733. 1931.—Functional suppression of the carotid sinus was studied in chloroformed dogs. Two ligatures were made in the posterior wall of the left ventricle to produce local alterations in the cardiac muscle. Tracings were made before and after the bilateral extirpation of the first thoracic ganglion. When the myocardium and the nerves of the heart are intact, suppression produces a rise in blood pressure and an acceleration of the pulse. When the common carotids are occluded, after the sympathetic nerves of the heart have been cut, excitation of the sinus or its functional suppression produce inhibitory results (slowing of the pulse, etc.). Functional suppression of the sinus produces cardiac inhibition only when the contractility is destroyed. If the myocardium is strong, inhibition does not occur, even if the sympathetic nerves are cut. Survival of patients having angina pectoris who have had the stellate ganglion removed depends on the condition of the myocardium.—*E. Weiner.*

10124. DUKES, H. H., and L. H. SCHWARTE. The blood pressure of the pig and the influence of non-nervous and nervous factors on the cardiovascular apparatus. *Jour. Amer. Vet. Med. Assoc.* 32(1): 37-62. 21 fig. 1931.—Mean blood pressure in the ligated carotid artery of 14 pigs under local anesthesia was determined, the average for the group being 169 mm. Hg. The effect of gravity on blood pressure was similar to the effect reported by others for certain other animals. Compression of the abdomen caused a rise in blood pressure as did asphyxia, but ligation of both carotid arteries had little or no effect. In a pig under local anesthesia, ligation of both carotid arteries appeared to impair but did not abolish consciousness. The action of adrenalin and pituitrin on blood pressure in the pig was similar to their action in other species, and indications are that vagus tone is fairly well developed. Cardiac inhibitory action was better developed in the right vagus nerve than in the left. In a pig no evidence was found of the existence of accelerator fibers in the cervical vagus nerve (right). Stimulation of the central end of the vagus nerve or of the central end of the sciatic nerve caused a rise of blood pressure more often than a fall. Acceleration and augmentation of the heart beat followed stimulation of the cardiac plexus of the pig. Stimulation in the region of the sino-auricular node caused cardiac acceleration. Stimulation of the peripheral and central end of the splanchnic nerve caused a rise of blood pressure, and also stimulation of the central end of the sympathetic trunk (right) opposite the fourteenth rib. —*From authors' summary.*

10126. FIELD, MADELEINE E., and CECIL K. DRINKER. The permeability of the capillaries of the dog to protein. *Amer. Jour. Physiol.* 97(1): 40-51. 1931. —Experiments on dogs showed that the capillaries of the subcutaneous tissues permit the passage of protein through their endothelial walls, the protein being detected in the cervical lymph 1 to 2 hrs. after injection. Normal serum, injected subcutaneously, is rapidly absorbed by the lymphatics, as shown by a concentration of the lymph and by the presence of foreign serum which can be detected serologically. The absorption is not due to puncture of the lymphatic vessels at the time of the injection. Fat is absorbed by the subcutaneous lymphatics but much more slowly than protein. The lymphatics of the peritoneal cavity which enter the thoracic duct take up protein even more readily than do those of the subcutaneous tissues. The blood capillaries of the subcutaneous tissues are not normally concerned in the absorption of protein. The blood capillaries of the peritoneal cavity are capable of absorbing extravascular protein. The omental vessels are probably most concerned in this absorption.

10127. FISCHER, M. H. Reizversuche mit "Wärmestrahlung" am Zentralnervensystem. *Zeitschr. Ges. Exp. Med.* 68(1/4): 139-144. 1929.—With a simple irradiation

method the sinus, atria, ventricle and atrioventricular junction of isolated frog hearts in Gaskell suspension were heated locally. Isolated irradiation of the sinus slowed the atria and weakened their contraction. An A-V block set in, which finally became complete. Long continued sinus irradiation produced arrest of the ventricle, atria and finally the sinus. The effects are attributed to a gradual decrease in the capacity of the sinus to originate excitation, resulting finally in complete "heat paralysis." Local irradiation of the atria or of the ventricles provoked a gradually spreading heat paralysis of the irradiated muscle, accompanied by a decrease in the extent of contraction therein. Local irradiation of the A-V junction produced A-V block, with idioventricular rhythm and extrasystoles in the atria which were beating in sinus rhythm. All the phenomena described are completely reversible on withdrawal of the irradiation.—*M. H. Fischer (transl. by W. J. Meek).*

10132. **GLEY, PIERRE, et D.-M. GOMEZ. La détermination de la pression moyenne par la méthode oscillométrique.** *Jour. Physiol. et Path. Gén.* 29(1): 38-41. 1 pl., 2 fig. 1931.—By "mean dynamic pressure" is meant the constant pressure that will maintain the same head of circulation as that due to the variable vascular pressure. It is equivalent to the "pression efficace intra-artérielle" of V. Pachon, and must be distinguished from the mean pressure obtained by arithmetical calculation from the observed maximum and minimum pressures. When measured in the living animal by a Marey compensation-manometer, it is found that the mean dynamic pressure corresponds closely to the point of maximal oscillation as observed in clinical sphygmomanometry.—*W. R. Fearon.*

10133. **GORJAJEW, N. K., M. SERGIJEWSKY, und J. ZWETKOW. Zur Frage des Ursprungs der Traube-Heringschen Wellen.** *Pflüger's Arch. Ges. Physiol.* 227 (1/2): 45-56. 8 fig. 1931.—The authors consider these waves to have a peripheral origin and to be at any rate partly dependent on variations in activity of the adrenals. When these glands are removed, the waves are no longer seen. They are not interfered with by section of the vagi, of the splanchnic nerves or of the sympathetic chain.—*H. C. Bazett.*

10134. **GOTTHARDT, PAUL PETER. Herz und Sport.** *Münchener Med. Wochenschr.* 76(27): 1117-1120. 1 fig. 1929.—This is a condensed preliminary report and deals with the question whether or not strenuous athletic exercise of certain types leads to enlargement (work hypertrophy) of the heart. Various difficulties peculiar to the problem are discussed at length. X-ray measurements of the transverse cardiac diameter (with some blood pressure and pulse rate determinations) were made on 467 skiers and a total of 156 runners, acrobats, boxers, swimmers and rowers. If certain important precautions are observed, on a large enough number of subjects, it can be shown that the transverse diameter of the heart is not often increased by the types of athletics mentioned. In some individuals, e.g., boxers, it even decreases. Under the circumstances, the terms "increased filling" and "thickening of the heart wall" are preferable to "dilatation" and "hypertrophy," which have a pathologic significance.—*M. Dresbach.*

10135. **GREENBURG, LEONARD. Changes produced in the distribution of the blood supply of the skin and the upper respiratory tract by the application of localized drafts of air.** *Yale Jour. Biol. and Med.* 3(4): 341-354. 1931.—In 26 experiments on 7 nude human subjects, exposed to drafts on the head and feet (remainder of body shielded by a screen), temp. observations of the skin, of the mucous membranes of the nose and throat, and of body temp. were made by a thermoelectric system. The environmental conditions were studied and the cooling power expressed on a basis of effective temp. It is concluded that skin temp. under any set of conditions is characteristic of the individual and varies with the effective temp. at which the body is exposed. At high effective temp. the skin tends to possess a uniform temp., while at lower effective temp. the temp. of the skin of the extremities falls below that of the remainder of the body. Exposure of an extremity (head or foot) lowered the temp. of that extremity. Exposure of the feet to a draft produced a fall of temp. of the head in approximately 65% of the experiments; after cessation of the draft, there was a slow return of the original temp. in the head and feet. Exposure of the head to draft is followed by a slow return of temp. to the feet and a rapid return of temp. to the head. The temp. of the nasal mucosa was lowered in 75-80% of these experiments on the exposure of the subject to a draft, whereas the temp. of the palatine tonsils was lowered in 60% of the experiments. Glatzel mirror studies indicate that the breathing space of the nose was increased in 50-64% of the experiments. It is rather difficult to reduce the temp. of the human body by exposure to cold to the extent practiced in these experiments, the av. change of temp. being a fall of 0.13° on exposure to a draft. The temp. studies of the nose and throat, as well as observations on the size of the nasal breathing space, the Glatzel mirror records, and the color of the mucous membranes all agree in indicating the production of a shrunken, pale mucosa of a lower temp. than that existing before the application of the localized draft.—*From author's summary and conclusions.*

Physiol.* 93(2): 536-543. 1930.—Results on a healthy ♂ subject showed that, under strictly basal conditions, the cardiac output of man is constant from day to day and is not subject to daily or seasonal variations.

10137. **[GRUZIN, A. I.]** ГРУЗИН, А. И. К вопросу о колебаниях артериального кровяного давления в зависимости от некоторых факторов. **[Dependence of arterial blood pressure on certain factors.]** [German summary.] Одесский Медицинский Журнал (*Odessaer Med. Zeitschr.*) 4(8/10): 529-540. 1929.—Persons with normal cardiovascular system and at rest gave comparatively slight oscillations of blood pressure (10-20 mm. Hg). Strenuous work together with unfavorable environment (high temp., air impurity, vapors, etc.), and

sports (volley ball and football) as well as serious psychic traumas produced even in persons with normal cardiovascular system large blood pressure oscillations (40-50 mm. Hg). In essential hypertonia, too, these oscillations were quite considerable. Large oscillations which, due to industrial conditions, are repeated daily over a period of many years, finally lead to permanently increased blood pressure, resulting in secondary phenomena, such as arteriosclerosis. Curves of maximal and minimal oscillations in many cases may be typical for certain diseases (glomerulonephritis, arteriosclerosis, hypertonia).—*B. Van Rosen.*

10138. HAMPERL, H. Zur Fragmentatio myocardii. *Beitr. Pathol. Anat. und Allg. Pathol.* 82(3): 597-601. 2 fig. 1929.—The author found that fragmentation of the heart muscle could not be produced definitely by experiment. In the human heart fragmentation was found only in necrotic regions. The position of the cross striations changed in contraction. These cross striations may represent boundaries between regions of different hydrogen ion concentration.

10139. HARTMAN, CARL G., R. R. SQUIER, and O. L. TINKLEPAUGH. The fetal heart rate in the monkey (Macacus rhesus). *Proc. Soc. Exp. Biol. & Med.* 28(3): 285-288. 1930.—The maternal pulse ranged from 160 to 240, the fetal from 100 to 180, at periods from 3 to 32 days prior to parturition and at a copulation age of 129 to 163 days. The rapid pulse of the pregnant monkey is explained as due to the excitement and vigorous exercise attending capture and subsequent struggles to escape.

10140. HOOKER, D. R. On the recovery of the heart in electric shock. *Amer. Jour. Physiol.* 91(1): 305-328. 2 fig. 1929.—Methods heretofore suggested for the recovery of the heart in electric shock have not been found efficacious. The new method here described calls for the central carotid injection of the remedial solutions, saturated with O and warmed to body temp., at a pressure of 150 mm. Hg. The arterial pressure being practically at 0, the solutions thus injected readily find their way into the coronary arteries. The first solution (KCl 0.5%, NaCl 0.9% plus heparin 0.25 mgm. per cc.), about 13 cc. per kgm., establishes K inhibition and the heart is allowed to rest for 1 min. The 2nd solution ($CaCl_2$, 0.023%; NaCl, 0.9%), about 25 cc. per kgm., washes the excess of K out of the coronary bed and substitutes a relative excess of $CaCl_2$, the effect of which is to stimulate a normal cardiac rhythm. This effect is enhanced by the coincident injection of 1 cc. of 1:1000 adrenalin chloride. In 12 experiments on dogs (of which 3 were killed) the heart was in fibrillation 1½-18½ min.; recovery was complete in 4 dogs, in 2 of which the heart had been in fibrillation for 5 min.

10141. KAHN, R. H., und FRANZ POLLAK. Die aktive Verengerung des Lumens der capillaren Blutgefässe. *Pflüger's Arch. Ges. Physiol.* 226(6): 799-807. 8 fig. 1931.—The contraction of capillaries has been studied in the nictitating membrane in the frog. The tissue has been excised so that variations secondary to changes in blood pressure can be excluded. Excellent photomicrographs are reproduced which strongly support the hypothesis that constriction of the capillaries can be of two kinds—one a diminution in the lumen as a result of the swelling of the endothelial cells, particularly their nuclei, and a second type in which adventitious cells lying outside the capillary exert pressure on the wall, changing the lumen and producing longitudinal folds in the vessel wall.—*H. C. Bazett.*

10142. KATZ, LOUIS N., and MORTIMER L. SIEGEL. The importance of the variable capacity of the aorta in averting "back pressure" in the right heart and pulmonary artery. *Amer. Jour. Physiol.* 89(2): 417-427. 1929.—An analysis of the effects of stenosis at the root of the aorta on the pulmonary circuit and right heart was made on the basis of optically recorded pressure pulses from these chambers (9 experiments reported). The following changes were noted immediately after a moderate stenosis of the aorta was made: (a) progressive rise in the pressure of the left auricle and pulmonary veins and a smaller rise in the vena cava after a short lag during which the pressure fell; (b) rise in the pulmonary arterial diastolic and systolic pressures; (c) increased pulse pressure in the pulmonary artery; (d) rise in initial pressure and in pressure amplitude in the right ventricle; (e) systolic vibrations in the left auricular pressure curve; (f) shift in the peak of the pulmonary arterial and right ventricular curve toward the latter part of ejection; (g) no significant changes in the duration of the cycle and systolic phases. The effects of changes in coronary flow which follow stenosis at the root of the aorta were evaluated by comparing the results of experiments in which the coronary return flow to the right heart was free with those of experiments where it was interrupted more than 60%. The coronary flow was interrupted either by occlusion of the sinus near its opening into the right auricle or by severing the sinus and allowing it to bleed freely. Except for the occasional absence of an increase in pulse pressure, no difference was noted in the 2 types of experiments, indicating that the changes in coronary flow play an unimportant part. The effects found are caused primarily by "back pressure" per se. The results indicate that moderate stenosis of the aorta leads to a damming back of blood in the pulmonary artery and right ventricle adequate in amt. to raise the pressure within them and augment the discharge of the latter. The additional capacity of the aorta is necessary to accommodate the excess blood and avert "back pressure." Compensatory changes follow very quickly. Evidence is given to show that they depend primarily on an increased discharge of the left ventricle which results from its increased distention with blood held back by the stenosis. The effect of aortic stenosis on the right heart varies with its degree. A greater degree of stenosis is needed to produce changes in the right heart than in the left. When the degree is excessive—the extent varying with the condition of the heart—a decrease in the pressure levels and pulse pressure eventually ensues because the right ventricle is distended beyond the physiological limit and its discharge decreased.—*Authors' summary.*

10143. KISCH, BRUNO. Der Calciumalternans. Ein Beispiel des Alternans bei systolisch disponiertem Herzen. *Zeitschr. Ges. Exp. Med.* 64(5/6): 666-679. 6 fig. 1929.—Total hyposystole is not found in Ca alternation. The increased duration and strength of systole appearing in the frog heart after excess Ca may lead to an alternating partial adiastole which may be expressed only by an alternation in the position reached by the bottom of the curves. In hearts with a systolic predisposition alternation is not preceded by weaker contractions. They may even be higher than normal. Alternation in hypodynamic hearts is to be referred to a disturbance in the assimilatory processes and a resulting decrease in energy output during systole, but in hearts with a systolic predisposition it is to be referred to an increase of the energy yielding processes during systole accompanying a more or less marked shortening of diastole. Negative inotropic substances such as acetaldehyde or Mg salts may abolish alternation in hearts with a systolic predisposition, while positive inotropic substances such as Ca salts may abolish it in hypodynamic hearts. Ca therefore aids both energy yielding and recovery processes. In man alternation appears mostly in cases with high blood pressure because in such hearts the systole is lengthened and the diastole shortened. Fundamentally every influence on the heart which increases the exhaustion processes during contraction and lessens the following recovery processes will lead to alternation as soon as the condition of luxus recovery is encroached upon.—*W. J. Meek.*

10144. KINSMAN, J. MURRAY, [et al.] Studies on the circulation. I. J. MURRAY KINSMAN, J. W. MOORE, and W. F. HAMILTON. Injection method: physical and mathematical considerations. II. JOHN WALKER MOORE, J. M. KINSMAN, W. F. HAMILTON, and R. G. SPURLING. Cardiac output determinations: comparison of the injection method with the direct Fick

procedure. *Amer. Jour. Physiol.* 89(2): 322-339. 6 fig. 1929.—I. Evidence is presented showing that it is possible to calculate accurately the flow of water through a system of tubes and bulbs, simulating the cardio-vascular apparatus of animals. The calculation is based upon the av. concentration and time relations of consecutive samples of the stream into which a dye has been injected. These samples serve equally well whether taken through large or small needles or from large or small branches of the stream. Curves obtained in experiments in which the water recirculates are similar to those in animal experiments. The confusion introduced by re-circulation is avoided by plotting the curve on semi-logarithmic paper. The descending limb of the primary wave is then a straight line and when prolonged serves to differentiate once-circulated from twice-circulated dye.—*Authors' summary.*—II. For the 1st time the accuracy of a method for calculating the cardiac output in man has been established by checking it in 6 experiments on 3 dogs against a reliable method, the direct Fick procedure. The results of 4 human experiments are included.

10145. [KUZNETSOV, V. P.] КУЗНЕЦОВ, В. П. Определение функционального состояния сосудов кожи. [Determining the functional condition of skin vessels.] [German summary.] Одеський Медичний Журнал (*Odessaer Med. Zeitschr.*) 5(3/5): 277-280. 1930.—The author describes a special dermograph which permits quantitative and qualitative calculation of the functional condition of the skin vascular-nervous apparatus. Irritation which produces the first reaction (white or red) is termed J_1. As the second limit is taken the force of irritation at which the reaction becomes opposite, and this force is termed J_2. Difference J_2-J_1 represents the dermographic index of the tonus of the skin vessels. This index is negative if the primary reaction was white, and positive if it was red. $J_2/J_1=J_{lim}$, and shows the limits of irritation, below which the reaction remains normal, and above which it becomes edematous.—*B. Van Rosen.*

10147. MARSCHAK, M. E. Hauttemperatur bei dynamischer und statischer Arbeit. *Arbeitsphysiologie* 3 (1/2): 168-178. 4 fig. 1930.—The skin temperatures of students, 24-28 years of age, were measured by means of a thermoelement in a room at 18-21°C. The dynamic work was raising and lowering weights, 5 to 20 kgm., for 2 to 6 min., stationary running 2 to 3 min., raising and lowering forearm, and bending thumb. The skin temperatures over the active muscles were always higher in the 3 successive periods during 5 min. after the work ended than before the work began. The temperatures of the skin over other parts of the body either remained unaltered or were lower after than before the beginning of the activity. The author concludes that the rise in temp. of the skin over the active muscles was due to an increased blood flow. The static work consisted of holding weights 4 to 20 kgm. with slightly bent arm or completely outstretched arm 1 to 5 min., holding weights while sitting, and holding body bent in a forward position. The temperatures of the skin over the contracted muscles fell during the exertion, and after the work ceased rose to nearly or above the prework level. The author concludes that the lowering of the skin temperature in static work was due to the hindrance to the blood flow.—*T. M. Carpenter.*

10148. MOORE, ROBERT M. The volume of the spleen in traumatic shock. *Amer. Jour. Physiol.* 89(3): 508-514. 1929.—The state of contraction of the spleen in cats in various stages of traumatic shock was studied in 10 experiments. In every instance the spleen was so extremely constricted that its cut surface did not bleed; its weight was 0.18-0.35% of the body weight, averaging 0.25%. These weights are similar to the lowest post mortem values obtained by Barcroft, Harris, Orahovats and Weiss in cats, and correspond to the minimum weight of the completely contracted spleen. Evidently, then, a dilated spleen is not a factor in the production of the decreased blood volume characteristic of traumatic shock. The close relationship between the contracted state of the spleen and of the splanchnic vascular bed is discussed. It is concluded that, as regards its smooth muscle, the spleen may be looked upon as a large and modified splanchnic blood vessel the volume of which serves as an index of the state of contraction of the splanchnic vascular bed as a whole. The occurrence of an extreme constriction of the spleen in traumatic shock is interpreted as supporting the observations of others to the effect that the splanchnic vasoconstrictor mechanism becomes highly active in shock in an attempt to maintain an effective blood pressure in the presence of a rapidly diminishing blood volume.—*Author's summary.*

10149. NI, TSANG-G. Does muscular contraction affect the local blood supply in the absence of lactic acid formation? *Jour. Physiol.* 71(4): 356-361. 1 fig. 1931. —Experiments on frogs with the spinal cord transected below the medulla showed that when the formation of lactic acid is prevented by poisoning with monoiodoacetic acid, muscular contraction can still increase the local blood supply by opening up more capillaries. Evidently lactic acid from the muscle is not an essential part of the mechanism which regulates the peripheral blood flow. Whether a humoral intervention of a substance other than lactic acid exists, is not discussed.—*Author's summary.*

10150. PUPILLI, G. Sui meccanismi vasomotori del polmone. I. Effetti di sezioni del tronco encefalico sui riflessi vasomotori polmonari. [The vasomotor mechanisms of the lung. I. Effects on the pulmonary vasomotor reflexes of section of the encephalic trunk.] *Ateneo Parmense* 2(3): 188-207. 1930.—From experiments on 6 dogs Pupilli concludes that in dogs decerebrated at the level of a plane passing immediately back of the caudal boundary of the colliculi posteriores it is no longer possible by stimulation of the central head of the crural nerve or stimulation of an intercostal nerve to elicit the pulmonary vasoconstriction reflex, though vasomotor reflexes can still be produced in the systemic circulation. Section of the central axis at a higher level (in the plane between the colliculi anteriores and posteriores) produces no appreciable modification in the vasomotor reflexes of the lung.

10151. RACHMILEWITZ, M., und D. SCHERF. Über extrasystolische und automatische Tätigkeit der Zentren. *Zeitschr. Klin. Med.* 114(6): 785-798. 1930.—In patients with auricular fibrillation who develop extrasystoles under digitalization it is found not infrequently that the beats which come after the post-extrasystolic pause arise from the same center as the extrasystole itself. Occasionally the extrasystoles are combined with these post-extrasystolic beats. The same thing is found under certain conditions without digitalis and without fibrillation both in the ventricle and in the auricle. Moreover, this phenomenon may be brought about experimentally. The fact that the same center produces successively automatic beats and extrasystoles raises the question whether the two types of impulse are identical or fundamentally different. It may be concluded that while many similarities exist between the automatic and extrasystolic stimuli, identification is not yet allowable, and the necessity for sharp separation remains.—*H. E. Jordan.*

10153. SKRAMLIK, EMIL von. Das Verhalten der Überleitungsgebilde zwischen Vorhof und Kammer gegenüber recht- und rückläufig übertragenen Antrieben. *Zeitschr. Wiss. Biol. Abt. C, Zeitschr. Vergleich. Physiol.* 13(3): 626-638. 1930.—The conducting structure between auricle and ventricle shows a certain polarity. In fish hearts (*Scyllium canicula* L.) it was found that currents of a given frequency from the ventricle are carried to

the auricle, but not from the auricle to the ventricle. Every contraction of the ventricle was followed later by one from the auricle. If, on the contrary, the auricle was stimulated with the same frequency, the stimulated structure responded but the ventricle responded to every second stimulus. In the frog heart (*Rana esculenta* L.) conditions were reversed. The conducting structure carried impulses of definite and uniform number per min. from the auricle to the ventricle, but not from the ventricle to the auricle. If the auricle was stimulated with frequent, rhythmical stimuli, it responded to every stimulus with a contraction, which was followed in a corresponding interval by one from the ventricle. If the ventricle was stimulated the auricle responded only to every second ventricular contraction. Since the transmission of stimulation in the fish heart occurred more slowly from the ventricle to the auricle than from the auricle to the ventricle, while in the frog heart, on the contrary, normal conduction of stimulation required shorter time than the retrograde, it can be said that the functions of the transmitting structure with regard to the rapidity of transmission of a stimulus and its response to 2 successive stimuli within a short period of time parallel one another.—*Author's conclusions (transl.)*.

10154. SPADAFINA, LUIGI. Ricerche sperimentali sulla influenza che esercita sulla pressione arteriosa il plasma sanguigno in confronto delle emazie. [Influence of blood plasma on arterial pressure as related to that of erythrocytes.] *Boll. Soc. Ital. Biol. Sperim.* 5(6): 829-832. 1930.—Diluting the blood with water until only ½ the number of erythrocytes were present had no marked effect on blood pressure. The same result was obtained by reducing the erythrocytes by pyrodine administration.—*M. Comel.*

10155. THÖRNER, WALTER. Beobachtungen über peripheren Kreislauf und Melanophoren unter dem Einfluss von Degeneration und Kationenwirkung in Durchspülungsversuchen am Frosch. *Pflüger's Arch. Ges. Physiol.* 222(1/2): 52-70. 1 fig. 1929.—Experiments are reported on the behavior of the capillaries and of the melanophores of the skin of the frog 2 to 3 mos. after excision of the right sciatic plexus. The results which are observed under a comparison microscope show a diminished tonus of the vessels. The diminished tonus was evidenced by better circulation, greater speed of blood flow and greater mass of blood transmitted. Perfusion experiments show that K causes an increased tonus of the vessels which is greater on the degenerated than on the normal side. The locus of action is the arteries. Calcium causes a smaller increase in tonus which has its seat in the capillaries. Sodium increases blood flow and diminishes normal tonus. Calcium produces contraction of the melanophores and K an expansion.—*H. C. Stevens.*

10156. TUTHILL, C. R. Hypertension in relation to the blood vessels of the medulla oblongata. *Arch. Path.* 11(5): 760-765. 2 fig. 1931.—The blood vessels of the region of the obex of the medulla oblongata were studied in 24 cases of hypertension of varying duration and in 35 cases of normal blood pressure. In 12 cases of hypertension, arteriosclerosis of the vessels of the medulla oblongata was found, but in the other 12 cases slight or no arteriosclerosis of these vessels was present. Among the cases of normal blood pressure, 6 showed arteriosclerosis of the vessels of the medulla oblongata. However, in none of the cases was arteriosclerosis confined solely to the vessels of the medulla. No proof was found that hypertension is the result of arteriosclerosis of the vessels of the medulla oblongata.—*Author's summary.*

10157. WARBURG, ERIK J. Über den Coronarkreislauf und über die Thrombose einer Coronararterie. I. Anatomie, Physiologie, und Historik. *Acta Med. Scandinavica* 73(5): 425-459. 4 fig. 1930.—A preliminary paper reviewing the background of the disease theory of thrombosis in a coronary artery. The author denies the validity of the conception implied by the term, "Myomalacia cordis." His interest is in the frequency of lung complications. The present paper describes the anatomy of capillary circulation, and the physiology of coronary circulation. The author has calculated the rate of the coronary circulation, using the relative sectional area of the aorta, the amount of work done by the heart, and with full consideration of previous studies on metabolism, the O capacity of the blood, and the efficiency of the heart muscle. During rest, the minute-volume of the coronary circulation is ¼ of a litre, as compared to 5 litres for the heart; and during maximum work the flow is 1 litre as compared to 30 litres for the heart. The paper reviews the literature on ligation of a great branch of a coronary artery, on coronary thrombosis, and on various aneurysms. The bibliography will be given in a 2nd paper.—*F. W. Appel.*

10158. WERTHEIMER, ERNST. Beitrag zur Frage des Stoffumsatzes beim Schlagen der Kaltblüterherzen. II. *Pflüger's Arch. Ges. Physiol.* 227(1/2): 100-109. 1931.—Strips of heart continue to beat when placed in Ringer's solution containing monobrom-acetic acid. This indicates that carbohydrate splitting is not of primary importance in relation to the muscle contractions. No significant changes in the concentrations of the various types of phosphoric acid were found to occur as the result of activity of heart strips.—*D. W. Wilson.*

Chem.* 183(4/6): 184-190. 1929.—With few exceptions, the amount of total P in the heart chambers increases in this order: right atrium—left atrium—right ventricle—left ventricle. Ventricles contain a greater proportion of phosphoric acid, phosphatid P and dry substance than atria (fresh beef hearts used). These points deserve study in pathological hearts.—*M. Dresbach.*

10160. WILSON, FRANK N., and GEORGE R. HERRMANN. Relation of QRS-interval to ventricular weight. *Brit. Jour. Surg.* 15(2): 135-140. 1930.—Comparison of the QRS-interval and the ventricular wt. [in 49 cases] indicates that the length of this interval increases in av. value with the cube root of the ventricular wt. Comparison of the QRS-interval and the thickness of the left ventricular wall shows a similar increase in the av. value of this interval with an increase in muscle thickness. QRS-intervals which exceed 0.10 sec. should not in general be ascribed to increased size of the heart or to increased thickness of the left ventricular wall alone, but to retarded intraventricular conduction.—*Authors' summary.*

10161. WOLFERTH, CHARLES C., and ALEXANDER MARGOLIES. The influence of auricular contraction on the first heart sound and the radial pulse. *Arch. Internal Med.* 46(6): 1048-1071. 1930.—A series of 7 cases with varying auriculoventricular relationships all showed inequalities of the 1st heart sound which could be related to the lengths of the intervals between auricular and ventricular systoles. These time relations tended to be characteristic for each case, although the degree of inequality varied and exceptionally could not be recorded. The inequalities of sound are easily detected by auscultation and furnish a valuable clinical test of dissociated beating of the auricles and ventricles (complete heart block and ventricular escape). The absence of inequality of sound does not rule out the possibility of dissociated beating. In 2 cases (both having complete heart block) inequalities in the size of the pulse waves were recorded. When the amplitude of the waves recorded was compared with the lengths of intervals between auricular and ventricular systoles, a definite relation was revealed. In both cases the curves showed similar time relations. In 1, inequalities in amplitude seemed to vary from day to day, and occasionally no differences could be recorded. In 3 other cases tracings of the pulse waves failed to reveal changes in the amplitude of the waves that could be related to the auriculoventricular intervals. Simultaneous records of changes in the intensity of sound and amplitude of the pulse waves showed that either comparatively loud or faint sounds may be associated with comparatively large or small pulse waves. It was therefore con-

cluded that while both types of changes were dependent on phenomena resulting from auricular systole, the factors concerned were not identical. It is suggested, principally on the basis of work by Wiggers and Gesell and some indirect evidence obtained by the authors, that the changes observed in the amplitude of the pulse waves are due principally to the effects of auricular systole on ventricular filling and initial tension. The provisional hypothesis is adopted that inequalities of the 1st heart sound observed are due principally to variation in the position of the mitral leaflets at the beginning of ventricular contraction.—*Authors' summary.*

Fisiol.* 29(2): 245-255. 6 fig. 1930.—A simple apparatus is adopted for studying the action of japaconitin A on isolated intestine. The action is exerted on the parasympathetic system, and especially on the vagus. The pendular movements of the intestine are controlled by the vagus, the static function or tonus may be controlled by the sympathetic system.—*M. Comel.*

10168. BENOIT, W. Über die Guajacolvergiftung des Kaninchens unter besonderer Berücksichtigung der Veränderungen an den Nieren. *Zeitschr. Ges. Exp. Med.* 62 (5/6): 585-613. 6 fig. 1928.—In the large doses used, guaiacol is a definite kidney poison. In the first 24 hrs. after administration almost the entire dose was excreted by the kidneys in the combined or conjugated form. Clinical symptoms included albumin, casts, and hemoglobin in the urine. The tubules were the site of injury, as with $HgCl_2$ and cantharidin. The glomeruli were injured but not to the same extent. Formation of granuloids as described by Kosugi in $HgCl_2$ poisoning was also noticed, but the expulsion of granuloids was not complete. The injured epithelial cells of the tubules exhibited characteristic droplets of albumin which may be regarded as a defense reaction. The union of such droplets gives rise to the albumin casts or cylinders in the urine. Retrograde extrusion of some of these cylinders into the glomeruli causes anuria due to mechanical factors. The hemoglobinuria is due to its filtration through the glomerulus into the lumen of the tubule where partial resorption by the tubule epithelium takes place. Results in acute guaiacol poisoning are additional support for the Ludwig-Cushny theory of kidney function in terms of filtration and retrograde resorption.—*W. N. Berg.*

10169. BERNHEIM, ERNST. Histohämorenale Verteilungsstudien. III. Tierexperimentelle Studien am Hunde. (Phenolsulfophthalein.) *Zeitschr. Klin. Med.* 104(1/2): 240-254. 1926.—Phenolsulphonephthalein was intravenously injected, after catheterization, into ♀ dogs (apparently 11), with and without narcosis, and the dogs unilaterally nephrectomized and killed at varying intervals after operation. Determination of the amount of dyestuff in the blood, the urine and the tissues at these various times showed that large quantities disappeared from the blood and were stored in the tissues before appearing in the urine, and that consequently excretion involves the tissues before it does the kidneys.

10170. BIANCALANA, LUIGI. Effetti delle iniezioni di soluzioni ipotoniche ed ipertoniche sul sistema cefalorachideo. [Effects of injection of hypotonic and hypertonic solutions on the cerebrospinal fluid.] *Arch. Sci. Med.* 54(6): 385-400. 1930.—Intravenous injections of great amounts of distilled water are not followed in dogs by any increase in cerebrospinal fluid pressure, nor by marked variations of the water content of the brain. Injections of hypertonic NaCl solutions are followed by a noticeable diminution of pressure, and by a slight diminution of the water content of the brain. In dogs in which a diminished pressure was artificially induced, injections of distilled water were followed by a rise of cerebrospinal pressure.—*M. Comel.*

10171. BIJLSMA, U. G. Solbrol (para-oxybenzoesaurer Methylester). *Arch. Internat. Pharmacodyn. et Thérap.* 34(2): 173-179. 3 fig. 1928.—The amount of methyl p-hydroxybenzoate (solbrol) necessary to give

retardation of growth of bacteria and of mycoderma is about equal to that of salicylic acid. The general toxicity is not high and its use as a preservative involves no danger. No observations have been made of danger to health, but the taking of large quantities cannot be serious, judging by experiments on young rats, where continuous administration of either solbrol or salicylic acid lowered the resistance to untoward external conditions. Without these conditions, up to 4 gm. per kgm. per day was borne without incident. Although both substances behave alike in retarding growth of micro-organisms and in influence upon young rats, solbrol had a significantly smaller influence on nitrogenous exchange in dogs. On the other hand, experience with solbrol has been very limited. A maximum dose of 250 mgm. for adults, corresponding to that for salicylic acid, would give only 54 mgm. of methyl alcohol and would certainly cause no trouble. This amount of solbrol would have an extraordinarily high value.—*E. V. Lynn.*

10172. BISCHOFF, FRITZ, and M. LOUISA LONG. Depletion of muscle sugar by adrenalin. II. *Amer. Jour. Physiol.* 95(2): 403-411. 1930.—The fall in muscle sugar below the resting level is observed during the recovery period following a subcut. or continuous intraven. dose of adrenalin. The effective subcut. and continuous intraven. muscle sugar lowering doses of adrenalin are the same. The minimum muscle sugar lowering dose of adrenalin is greater than the minimum hyperglycemic dose. A physiological rate of injection over a long period of time reduces the muscle sugar below normal. When the muscle sugar was observed to be low following the action of adrenalin, the muscle glycogen was also low, but normal or high muscle sugar values were found with low muscle glycogen values. Under conditions in which blood sugar, muscle sugar, and muscle glycogen were affected by adrenalin, the polysaccharide sugar of the muscle was unaffected.—*Authors' summary.*

10173. BLUMGART, HERRMAN L., DOROTHY ROURKE GILLIGAN, and JACOB H. SWARTZ. The elimination of ethyl iodide after inhalation and its relation to therapeutic administration. *Jour. Clin. Investigation* 9(4): 635-650. 1931.—In more than 200 patients it was found that after 1.0-3.0 cc. of ethyl iodide are introduced into the inspired air, an average of 45% is immediately exhaled during the period of treatment, an average of 9% is exhaled during the 1st 2 hrs. after treatment and 31% is excreted by the kidneys. This accounts for 85% of the total dose given, the other 15% being excreted in all probability by the intestines, skin, and in the sputum. Of the ethyl iodide excreted as iodide in the urine, approximately 85% is excreted within the 1st 24 hrs. and approximately 97% is excreted by the end of 48 hrs. Within the range of therapeutic dosage, the percentage of ethyl iodide retained in the body is independent of the size of the dose, of the length of time taken for inhalation and of the fluid intake and output.—*From authors' summary and conclusions.*

10174. BOURNE, ALECK, and J. H. BURN. The dosage and action of pituitary extract and of the ergot alkaloids on the uterus in labour, with a note on the action of adrenalin. *Jour. Obstetr. & Gynaecol. Brit. Emp.* 34(2): 249-272. 1 pl., 15 fig. 1927.—A dose of 2 units in 1 cc. of pituitary extract may be expected to produce an effect which should be useful in hastening the course of a sluggish labour, provided it is not administered before the os is about ½ dilated. A dose of 2 units may be given with safety at any stage provided that there is no mechanical obstruction. The least interval at which any dose can be usefully repeated is 1 hr., but often the effect of 2 units has lasted longer than this. The action of the separate ergot alkaloids has been examined by the authors. It has been found that tyramine has no value in obstetrics. Histamin in a dose of 2.0 mgm., when injected under the skin, produces a powerful but short lived effect; it appears to exhaust the uterine activity. The specific alkaloid of ergot (ergotamine or ergotoxin) exerts a very prolonged action, and appears to be an ideal agent for use after delivery. Adrenalin, injected into a vein, inhibits uterine contraction before delivery; ether has a similar effect.—*From authors' summary.*

10175. BRÜDA, B. E., und W. M. KREINER. Über Oligodynamie. *Deutsche Zeitschr. Chir.* 228(6): 415-421. 1930.—Oxygen is not essential for the occurrence of oligodynamic action. Since, according to Kernst, it can be proven analytically that metals can go into solution directly, i.e., without previously forming a salt, ionic action on the part of the metals may be assumed. Ionic action is a physico-chemical phenomenon which satisfactorily explains the partially contradictory reports occurring in the literature. Oligodynamic action is a physico-chemical process involving free metallic ions.—*Authors' conclusions (transl. by B. S. Levine).*

10176. BRUNELLI, BRUNO. Schok arsenobenzolico. Crisi globulinolitica. [Shock from arsenobenzene. Globulin crisis.] *Arch. Sci. Med.* 54(10): 733-773. 10 fig. 1930.—The administration of arsenobenzenes with semi-colloidal constitution into the blood stream of individuals with altered colloidal stability of plasma induces a lysis of seroglobulins and thrombocytes. The proteolysis is shown by increase of non coagulable N and of reducing substances, by decrease of refractometric index, by modification of the ultramicroscopic structure of plasma, by the appearance in the plasma of histamine-like substances, by positive Abderhalden and Fehling reactions in the dialysate of plasma. The cause of shock from arsenobenzene may be the setting free of histamine-like substances. The faculty of provoking proteolysis is shown by arsenobenzenes as well as by all substances which behave as colloids or semi-colloids with electro-negative polyvalence. The proteolytic crisis is due to the introduction into the blood stream of colloidal or semi-colloidal substances and by the existence in the given subject of a colloidal lability of plasma.—*M. Comel.*

10177. CAIUS, J. F. The toxicity of the venom of Indian scorpions. *Jour. Bombay Nat. Hist. Soc.* 34(3): 788-789. 1930.—The toxicity of the venom in a male specimen of *Buthus alticōla* Pocock is here recorded. A description of the specimen is also given.—*S. Ribeiro.*

10178. CERUTI, G. L'eccitabilità riflessa nel diabete florizinico e nell'iperglicemia. [Reflex excitability in phloridzin diabetes and hyperglycemia.] *Arch. Fisiol.* 29(2): 234-244. 1930.—Ablation of the pancreas is followed in rabbits by a diminution of the reflex excitability, which develops at the same time as hyperglycemia. When the latter is decreased following regeneration of some fragments of pancreas, the reflex excitability is increased. Also alimentary hyperglycemia, and that induced by glucose injections, are followed by a diminution of reflex excitability. In phloridzin diabetes a diminution of reflex excitability is accompanied by hypoglycemia, the diminution probably being due to a direct action of phloridzin on the nerve-centers.—*M. Comel.*

10179. CHIARIELLO, ALFONSO GIOVANNI. Le variazioni della lipemia nelle narcosi cloroformica ed eterea. [Variations in the blood lipids in chloroform and ether narcosis.] *Ann. Ital. Chir.* 9(9): 853-864. 1930.—In 6 experiments with chloroform and 4 with ether on dogs, blood samples were taken every ½ hr. In both forms of narcosis a hyperlipemia (alternating with periods of depression) was predominant. In the chloroform narcosis free cholesterol and neutral fats were chiefly responsible for the hyperlipemia; in the ether narcosis the fact that the cholesterol ethers are more abundant than free cholesterol, would indicate a more pronounced reaction of the antitoxic mechanism (suprarenal cortex) of the organism.

10180. CHIODO, A. Action combinée du camphre et du salicylate de sodium. Influence du salicylate sur l'action pharmacologique de l'hexetone. *Arch. Internat. Physiol.* 31(2): 89-120. 10 fig. 1928.—The M. F. D. of

camphor, sodium salicylate and hexetone has been determined for the frog. In addition the minimal active and minimal arrest dosage of these compounds has been determined for the isolated heart and the character of the cardiac reaction described. In general, camphor has a negative inotropic and chronotropic action on the heart in all active concentrations. In toxic dosages a distinct depression of the nervous system occurs. Salicylate has a positive inotropic and chronotropic action on the heart. Hexetone acts like camphor. Salicylate antagonizes the depressive effects of camphor on the heart, but camphor also tends to antagonize the cardiac reaction to toxic salicylate concentration. Salicylate toxicity is enhanced by small dosages of camphor on simultaneous administration. Salicylate also seems to antagonize the toxic effects of camphor on simultaneous administration. The reaction of the frog to salicylate and camphor or hexetone, i.e., whether a summation, antagonism or potentiation occurs, depends on the ratio between the administered dosages of the 2 compounds. The theory of action is discussed.—*O. W. Barlow.*

10181. **CHISTONI, A. Ricerche farmacologiche sulla canfora della "Meriandra benghalensis." [The camphor of M. benghalensis.]** *Ateneo Parmense* 2(6): 611-613. 1930.—The essential oil of *M. benghalensis* and the camphor obtained from it possess pharmacologic properties identical with those of the camphor from *Cinnamomum camphora.—Author's summary. (transl.).*

10182. **CHISTONI, A. Intorno al meccanismo di azione del cloruro di bario. [Mechanism of the action of $BaCl_2$.]** *Boll. Soc. Ital. Biol. Sperim.* 5(5): 786-788. 1930.—The intensity of purgative action of $BaCl_2$ is related to the reactivity of the parasympathetic tonus of intestine; by increasing vagal tonus with pilocarpine, a smaller dose of $BaCl_2$ may exert a purgative action.—*M. Comel.*

10183. **CHOPRA, R. N., K. S. GREWAL, J. S. CHOWHAN, and G. S. CHOPRA. Addiction to "post" (unlanced capsules of Papaver somniferum) in India.** *Indian Jour. Med. Res.* 17(4): 985-1007. 1930.—With present restriction of poppy cultivation, addiction is practically limited to Punjab districts. Analyses of unlanced capsules show that as compared with opium, they contain much less morphine, but much more codeine, narcotine and papaverine. These latter alkaloids have a weaker depressant action on the psychical areas and a weaker analgesic effect, in fact some of them actually act as excitants. The symptoms, therefore, differ somewhat from those produced by opium indulgence, and resemble in some respects those produced by cocaine, though on a much milder scale. An analytic study of 530 cases of addiction to poppy heads or "post" has been carried out, and different factors in connection with its causation, dosage, symptoms and effects produced have been recorded.

10184. **CHOPRA, R. N., and PREMANKUR DE. The action of a sympathomimetic alkaloid in Sida cordifolia (Brela). (Indigenous drugs series no. 24.)** *Indian Jour. Med. Res.* 18(2): 467-475. 3 pl. 1930.—The active principle of *Sida cordifolia* (Brela) is an alkaloid with well-marked sympathomimetic action. A detailed study of the pharmacological action of this alkaloid on various tissues and organs shows that its action closely resembles ephedrine. Further work on its chemistry is in progress to determine if the alkaloid is ephedrine or a closely allied compound.—*Authors' summary and conclusions.*

10185. **CHOPRA, R. N. (In collab. with GURBAKSH SINGH CHOPRA). Cocaine habit in India. (Drug Addiction Series, no. 8.)** *Indian Jour. Med. Res.* 18(3): 1013-1046. Map. 3 pl. (2 col.). 1931.—The cocaine habit is of comparatively recent origin in India. The earliest records of its use are not more than 40 to 45 yrs. old. *Erythroxylon coca* has never been grown in India on a large scale; so far as is known no other varieties of *Erythroxylon* which bear cocaine and grow in India in a state of nature are cultivated. There is no ground whatever for the belief that cocaine is secretly manufactured in India. The leaves of *E. coca,* which have been largely indulged in by the inhabitants of S. America for several hundred years, have never been used in India for their euphoric effects. It is the alkaloid cocaine which was and is still used. The habit was prevalent in many towns in India at the beginning of this century when the evil effects produced by it came to the notice of the medical profession and the authorities. Restrictions were at once placed on the import, sale, possession, transport and use of the alkaloid and preparations containing it. Yet the habit spread from Calcutta to large towns along the 2 main railway routes through the United Provinces into the Punjab and the North-West Frontier Province. From Bombay it spread to some large towns in that presidency. The drug is smuggled into India in large quantities through sea ports particularly Calcutta and is distributed to different parts of the country by the smuggling organizations. For some time past the Far East has driven the European and American manufactured product out of the market, Japan being the chief source now. The drug is illicitly brought by crews of various lines of mercantile marine running between Japan and Calcutta. The habit is chiefly prevalent among the betel leaf chewing population of north-western portions of India (including Bengal, Bihar, United Provinces and the Punjab). It is estimated that about a half to 1 million cocaine eaters belonging to different strata of society exist in India. The habit is not only present among the well-to-do population but a large number of the artisan class in large towns are also its victims. Cocaine sold in India is very heavily adulterated, the chief adulterants used being phenozone, phenacetine, caffeine citrate, acetyl salicylate and KNO_3. Two hundred addicts have been carefully studied and analytical data regarding the causes leading to the habit, the duration of addiction, occupation of the addict, dosage, sex incidence, its effects on sexual functions and fecundity, association of cocaine habit with other drug habits, etc., have been discussed. Of the main causes leading to addiction, association with other addicts is an important factor accounting for 66.0% of cases in this series, luxury and pleasure account for 21%, fatigues, worry and strain for 6.5%, curiosity and fancy for 4.5% and disease for 2%. The habit is chiefly confined to individuals whose psychic condition is unstable. The most common method of taking cocaine in India is by putting it in a "pan" or betel leaf. The drug is either mixed with the spices which are usually put in the leaf, or some of the addicts place the alkaloid on the dorsum of the tongue and then chew the leaf afterwards. Addicts of long standing generally put cocaine on the tongue and follow it up by a little lime and catechu, dispensing with the the betel leaf. This is said to enhance the action of the drug. The method of taking the drug by injection or in the form of snuff is unknown in this country. The symptoms produced by cocaine eating as observed from a study of 200 cases have been described in detail and the deleterious effects of the habit on the physical, mental and moral condition of the addict have been discussed. Diagnosis of cocaine habit and its treatment have been described. The appearance of the addicts is typical. They are emaciated individuals with a sallow complexion, sunken eyes, wrinkled face and dilated pupils. They have a dark chocolate colored deposit on the teeth and the tongue which is considered to be pathognomic.—*Authors' summary and conclusions.*

10186. **CIAMBELLOTTI, EDOARDO. Il comportamento dell'uricemia, glicemia e cloremia dopo somministratione di Calcio. [Effect of the administration of calcium in uremia, glycemia and chloremia.]** *Arch. Ital. Dermatol. Sifilogr. e Venereol.* 3(1): (1-32). 9 fig. 1927.—The results of the intraven. administration of inorganic and organic Ca in the stated conditions were beneficial and permanent. Improvement in dermatoses was parallel with the change in blood findings. Ca acts not only in mobilizing K and Na, but involves a col-

loidoclasia. Case histories with charts and bibliography are included.—*A. E. Taft.*

10187. CIAMBELLOTTI, E. Studio di un sale organico di stronzio. I. Ricerche storiche, farmacologiche, fisiologiche e biologiche. [An organic salt of strontium. I. Historical, pharmacologic, physiologic and biologic studies.] *Gior. Ital. Derm. e Sifil.* 71(1): 96-140. 1930.—The salt studied is "418 Sr," a hexose oxypropionate of Sr, said to be only slightly toxic, suitable for either intraven. or intramusc. administration; the Sr ion constitutes the active portion. Studies on 3-11 patients showed, after administration of "418 Sr," a more or less constant increase in blood urea, a varied response, with predominance of increase, of blood sugar, a marked fall in alkaline reserve, sometimes amounting to acidosis, negative results on basal metabolism, absence of circulatory disturbances and of toxic action on the kidneys, and an effect on the vegetative nervous system equal to that of Ca.

10188. CLARK, G. A. The selective vaso-constrictor action of adrenaline. *Jour. Physiol.* 69(2): 171-184. 9 fig. 1930.—Epinephrine in amount great enough to raise the blood-pressure in cats and rabbits causes a prolonged vaso-constriction in skin vessels, but an increase in the volume of blood present in voluntary muscle and in the intestine. The results in cats have been obtained on animals anesthetized with chloralose, amytal and urethane and after decerebration. The observed vaso-dilatation in the intestine is produced partly by reflex nervous means, but is also seen when all possibility of such reflexes is removed by section of vagi and splanchnic nerves; the dilatation can be diminished by electrical stimulation of the splanchnic. When a rise of blood-pressure is prevented epinephrine constricts the intestinal vessels, but the constriction is of a more transient and feebler nature than that seen in the skin. Back pressure from the portal system plays little part in the vaso-dilatation of the gut. It seems that the rise in portal venous pressure following an injection of epinephrine must to some degree be enhanced by the increased blood flow through the splanchnic area.—*Author's summary and conclusions.*

[Reduction of m-dinitrobenzene, respiratory metabolism and pH.] *Arch. di Sci. Biol.* 13(1/2): 158-184. 4 fig. 1929.—Reduction of m-dinitrobenzene to m-nitrophenylhydroxylamine by frog muscle depends on pH of medium; the optimum is near neutrality. The reduction is diminished on the acid side. The rate of reduction is proportional to the length of the experiment but not to the gaseous exchange; the slowing can be referred to the poisonous action of m-nitrophenylhydroxylamine. —*A. Jappelli.*

10192. CORI, C. F., and K. W. BUCHWALD. Effect of continuous intravenous injection of epinephrine on the carbohydrate metabolism, basal metabolism and vascular system of normal men. *Amer. Jour. Physiol.* 95(1): 71-78. 1930.—Epinephrine was injected intravenously into [9] normal men [in 17 exps.] for a period of 30 min.; 0.00005 mgm. per kgm. per min. proved to be the lowest rate of injection which still caused a rise in blood pressure, blood lactic acid and basal metabolism; 0.000025 mgm. per kgm. per min. was still able to increase pulse rate, respiration and blood sugar. After the epinephrine administration pulse rate, respiration and blood pressure returned to the original level in 5-10 min., basal metabolism in 15-30 min., while generally more than 30 min. were required for blood sugar and blood lactic acid.—*Authors' summary.*

10193. CORI, G. T. Effect of epinephrine on sugar utilization in animals under amytal anesthesia. *Amer. Jour. Physiol.* 95(2): 285-291. 1930.—Amytal anesthesia, which in itself has but a slight effect, greatly intensified the depressive action of epinephrine on glucose utilization.

10194. CORI, GERTY T. The mechanism of epinephrine action. VII. Changes in the glycogen, lactic acid and phosphate content of muscle. *Amer. Jour. Physiol.* 94(3): 557-563. 1930.—The glycogen content of the right and left gastrocnemius muscle, when extirpated at 30 min. intervals from rats under amytal anesthesia (6, and 6 controls), was found to be of the same magnitude. When after extirpation of the 1st muscle epinephrine was injected either subcutaneously or by means of an intravenous infusion at a constant rate, a definite reduction in the glycogen content of the 2nd muscle was always encountered (6 experimental rats and 6 controls). Twenty and 40 min. after epinephrine injection the phosphocreatine content of muscle was practically unchanged, the inorganic phosphate showed a slight decrease and the lactic acid content of muscle and of blood was markedly elevated.—*Author's summary.*

10195. CORTELLA, EMILIO. Nuove ricerche sulle alterazioni del sistema nervoso centrale nella intossicazione da acetato di tallio. III. Le alterazioni delle fibre dell'encefalo, delle fibre e delle cellule del midollo spinale. [Changes in the central nervous system from thallium acetate intoxication. III. Changes in the fibers of the brain and in the fibers and the cells of the spinal cord.] *Gior. Ital. Derm. e Sifil.* 71(5): 1661-1672. 1 pl. 1930.—Of 25 rats used 13 received a heavy total divided dosage of Tl acetate; 8 received various multiple but individually infinitesimal doses (minimum 0.047 μgm., maximum 5 μgm. Tl), while 4 received each a single dose, resp. strong, medium and weak. Even small doses produced clinical symptoms and corresponding pathologic changes. The alterations in the central cerebral fibers consisted in thinning and circumscribed thickening of the myelin sheath, sometimes forming detached, irregular beads, and in local tortuous and fiber-like swellings of the axis-cylinders, forming twisted appearances like a skein of wool. In the fibers of the spinal cord similar phenomena were present, and, in addition, small hemorrhagic foci, especially in the white substance. The cells of the spinal cord were spheroidal, and the nucleus was deformed and displaced toward the periphery. The condition is diagnosed as encephalomyelitis with degenerative neuritis.

10196. CZIKE, ANTON von. Lungenvolumenuntersuchungen unter Einwirkung von Atropin, Adrenalin und Strophantin. *Zeitschr. Ges. Exp. Med.* 74(1/2): 20-31. 1930.—The lung volume can be altered by the action of drugs on the respiratory center or on the autonomic endings. These changes are due to the activity of the autonomic system. In healthy persons no relation between changes in lung volume and circulatory changes was found. After atropine the vital capacity was smaller, due to a considerable decrease in expiration. Inspiration is somewhat greater. After epinephrine the vital capacity yielded higher values, explained by more complete expiration. The extent of inspiration varies, and generally falls slightly. The volume relationships in asthma can not be studied during the

attack because of air hunger; after injection of epinephrine they are in accord with the known physiological and pharmacological actions of epinephrine. The increase in volume due to epinephrine can be prevented by atropine, and vice versa. After injection of strophanthin the vital capacity is raised slightly, due to deeper inspiration. The expiration varies but slightly. The effect of strophanthin on the vital capacity can be inhibited by atropine; there then appears the characteristic atropine effect on expiration, that is, the supplemental air is low, while the striking increase in inspiration can be attributed to the combined action of both drugs. Hypophyseal extracts have no effect on the lung volume.—*Author's summary (transl. by B. R. Lutz).*

10197. **DOLFINI, GIULIO, e GIUSEPPE ZANETTIN. Modificazioni ematologiche da olio di croton colloidale.** [Hematologic modifications induced by colloidal croton oil.] *Arch. Sci. Med.* 54(5): 337-351. 1930.—Intravenous administration of a colloidal solution of croton oil is followed in rabbits by an intensive irritative action on the reticulo-endothelial system, which may lead to necrosis. If India ink is previously administered the injection of croton oil is followed by discharge into the blood stream of great numbers of endothelial cells, monocytes and granulocytes, which are loaded with ink granules.—*M. Comel.*

10198. **DUCRET, S. Die Reaktion der Coronararterie auf Adrenalin.** *Pflüger's Arch. Ges. Physiol.* 225(5/6): 680-685. 5 fig. 1930.—Epinephrine has a consistent dilator action on the coronary arteries. In order to obtain a maximum epinephrine effect the coronary vessels must be in a special condition of tonus, which corresponds to a load of 0.2 gm. per mm.² of the wall (media and adventitia), or 0.13 gm. per mm.² of the muscular layer. The dilatation is influenced by the following factors. It is dependent on the Ca content of the nutritive solution. An acid as well as an alkaline medium decreases the dilatation. By lowering the temp. an epinephrine dilatation can be prevented. Oxygen has a tonic influence on the vessels. The dilatation is less on coronary vessels of old animals and on vessels kept a long time. The coronary vessels contract with $BaCl_2$.—*Author's summary (transl. by B. R. Lutz).*

10199. **DUKE-ELDER, W. S., and P. M. DUKE-ELDER. The contraction of the extrinsic muscles of the eye by choline and nicotine.** *Proc. Roy. Soc.* [*London*] B 107(751): 332-343. 9 fig. 1930.—Choline, acetylcholine and nicotine produce a slow, tonic contraction of the normal extrinsic muscles of the eye. This is the only recorded example of this type of contraction occurring in the non-denervated voluntary muscles of mammals. In this respect the ocular muscles of mammals resemble the voluntary muscles of species below mammalia, or the other voluntary muscles of mammalia before they have received their motor nerve supply or after they have been deprived of it. The contraction is unaffected by atropine, increased by adrenaline, and abolished by nicotine and curare. The morphological basis of this unique behavior of these muscles is discussed.—*W. S. Duke-Elder.*

10200. **FILIPPIS, V. de. A proposito di un tentativo di chemioterapia della rabbia.** [Chemotherapy of rabies.] *Ateneo Parmense* 2(6): 603-610. 1930.—Small repeated doses of aqueous solution of Pb acetate were injected into 10 rabbits, which, together with 2 controls, were subcutaneously inoculated (15 days after the end of the Pb treatment) with rabies; 1 experimental animal and 1 control died. Reinoculation (intramuscular) was without result, but intraocular reinoculation caused the death of the remaining control. Filippis concludes that small repeated doses of Pb acetate increase somewhat the rabbit's resistance to rabies, probably by increasing the defensive function of the reticulo-endothelial system. Large doses of nucleoprotein extracted from the nervous system of rabbits preventively treated with Pb acetate seemed to increase the susceptibility of 2 normal rabbits to rabies, but small doses in a 3rd rabbit appeared to be protective.

10201. **GERLÓCZY, GÉZA, und GÁBOR BERENCSY. Der Einfluss der peroralen Verabreichung von $NaHCO_3$ und von NH_4Cl auf die $CaCl_2$-Resorptionsverhältnisse. II.** *Zeitschr. Ges. Exp. Med.* 73(5/6): 715-719. 1930.—Studies were made on 20 patients with slight maladies. Administration of 200 gm. $NaHCO_3$ within 3 days previous to administration of 10% $CaCl_2$ solution in dosage of 0.15 gm. per kgm. body weight raised the blood Ca on the average about 88% more than the same dose of $CaCl_2$ given without previous alkalinization but otherwise under the same conditions. When 24 gm. NH_4Cl was given during the 72 hrs. preceding the dose of $CaCl_2$, the blood Ca rose, on the average, about 1.83 less than when given without NH_4Cl. $CaCl_2$ given in physiologic NaCl solution was followed by a 43.4% higher Ca concentration, when given after alkalinization, and 22.7% higher when given after NH_4Cl, than the control experiments.

10202. **GIACOMO, UMBERTO de. Ulteriori dati sull' azione della bulbocapnina.** [Action of bulbocapnin.] *Boll. Soc. Ital. Biol. Sperim.* 5(5): 757-758. 1930.—In some cases cataleptic symptoms without muscular hypertony followed administration of bulbocapnin.—*M. Comel.*

10203. **GIAJA, J., et X. GHAHOVITCH. Sur l'influence de l'alcool sur la puissance thermogène de l'organisme.** [With French résumé.] *Glas. Srpska Kralevska Akademija* [*Belgrade*] 1926(122): 61-67. 1926.—Ethyl alcohol subcut. or per os decreases the rate of summit metabolism in the rat even in small doses, which do not affect basal metabolism. Thus, in doses of 0.9, 2.7 and 3.0 cc. per kgm., alcohol lowered summit metabolism resp. 5.6, 18.0 and 11.4%, whereas these same doses did not alter the rate of basal metabolism. In stronger, intoxicating doses (4.2 cc. per kgm.), alcohol decreases both summit and basal metabolism, the former however more than the latter, and the value of the metabolic quotient is thus decreased. At no time does alcohol increase the heat forming capacity of the organism, but on the contrary lowers it, even in moderate doses.

10204. **GIANOTTI, MARIO. La reazione all'adrenalina del territorio vasale dei tessuti infiammati.** [The reaction to epinephrine in the vascular area of inflamed tissues.] *Arch. Sci. Med.* 54(8): 515-541. 3 fig. 1930.—With a new graphic method it was possible to determine the intensity of vasoconstriction from the results obtained with the Rieschbieter-Bissemsky's method. Epinephrine exerts a vasoconstrictor action on the vascular area of inflamed tissues. Such action is less pronounced than that on uninjured tissues. The hypothesis of a possible alteration of the contractile elements and that of a possible rise of the threshold value for excitability of the neuro-muscular junctions are pointed out. *M. Comel.*

10205. **GOLD, HARRY. (In collaboration with PATRICK L. GRYZWACZ, and WALENTINE A. NOWICKI.) Electrocardiographic studies in the actions of drugs. 1. The vagus in ether anesthesia.** *Amer. Heart Jour.* 4(3): 336-345. 7 fig. 1929.—These exps. were performed on dogs to determine, by electrocardiographic examination, the effect of ether on vagus susceptibility to morphine stimulation. Within limits ether and morphine are found to be mutually antagonistic. Ether depresses the vagus and abolishes partially or completely the stimulating effect of morphine. After large doses of morphine, ether narcosis may abolish vagus effect on the sinus but not on conduction.—*M. Easby.*

10206. **GORDONOFF, T., O. SCHÜTZ, und W. SPYCHER. Pharmakologische Untersuchungen des Natrium citricum.** *Zeitschr. Ges. Exp. Med.* 74(3/4): 415-433. 1930.—Isolated frog's heart was paralyzed with Na citrate. The action begins at 1:1 million; 1:1000 stops the heart irreversibly. The action appears to be muscular. Small doses increased tone and peristalsis in isolated rat intestine; the same concentration paralyzed rabbit intestine. The rabbit reacted with a slight diar-

rhea the day after injection of large amounts of Na citrate. Intravenous doses in large amounts caused a transient lowering of blood pressure, followed by increases in 60-80 min. to a point higher than before the experiment. Intravenous doses of Na citrate cause a deepening of breathing, and in many cases a retardation. After the initial effect breathing becomes rapid and superficial. Intravenous doses larger than 150 mgm. per kgm. of body weight cause dyspnea, muscle spasms, unrest, diarrhea, deepening of breathing, at first a slight decrease in rate and then an increase. The erythrocytes are not changed in either form or size. In the blood stream large doses considerably diminish the number of thrombocytes. After overcoming the initial intoxication the rabbit acquires a temporary tolerance. A greater toxicity was not observed after an interval of 1-3 days. In equal amounts the toxicity is greater, the more rapid the injection and the higher the concentration. The urine of rabbits on a diet of oats and water contained no citrate. The amount of citrate found in the urine of rabbits given doses of 400 mgm. per kgm. of body weight, amounted to 4.39-6.15% if the injection was made in 3 periods of a total of 15-17 min. Normal human urine contains citrate. The amount is very variable. Since citrate can be detected in human urine it is difficult to differentiate between the amount of citrate in the food consumed and that used experimentally. The values found lie within the normal limits. —*Authors' summary (transl. by R. W. St. Clair).*

10207. GRABBE, CARL. Untersuchungen über Oxychinolin (Chinosol). *Arch. Exp. Path. u. Pharmakol.* 137(1/2): 96-115. 1928.—The author studied 8 hydroxyquinoline potassium bisulphate, 8 hydroxyquinoline sulphate and mono-iodo 8 hydroxyquinoline sulphonate (Yatren). Estimation of the substances was made either by a gravimetric method, using the ether extract of tissue fluids with bromine water, giving the insoluble dibromide or the colorimetric method using the color obtained with $FeCl_3$. The colorimetric method seems more sensitive than the gravimetric one. 8 Hydroxyquinoline is rapidly absorbed from the intestine of a normal dog and eliminated rapidly through the kidneys and gall bladder. Thereby it is transformed almost completely into the sulphuric acid ester, a change which occurs partially in the lumen of the small intestine. A small portion of the hydroxyquinoline remains free, and can be freed from its ester under the conditions in the organism. 8 Hydroxyquinoline has a distinct action upon the metabolism, demonstrated by increased urinary N elimination. This action occurs only 1-2 days after administration and reaches its maximum when the main portion of the drug has been excreted. In experiments with starved dogs, the increased formation of decomposition products is much more lasting and greater with hydroxyquinoline than with salicylic acid. Animals treated in the beginning of a fast with one dose of 8 hydroxyquinoline will show an early premortal protein decomposition. The starved animal eliminates 8 hydroxyquinoline much more slowly than the fed animal (in contrast to salicylic acid). If such an animal after a prolonged hunger period is fed, considerable quantities of 8 hydroxyquinoline appear in the urine.—*F. R. Greenbaum.*

Sperim.* 5(5): 768-770. 1930.—The Ca contents of serum decreased after administration of bulbocapnin, while the K content showed variable values.—*M. Comel.*

10209. HABERLANDT, L. Untersuchungen über einen Erregungsstoff im Centralnervensystem. *Med. Klinik* 25 (51): 1961-1964. 2 fig. 1929.—On the theory that the nervous system elaborates a substance analogous to a hormone, emulsions of brain and spinal cord of frogs and guinea pigs were injected into frogs, using 260 animals, including controls. In 48 hrs. or less the treated animals, regardless of sex, were considerably more active and seemed to have better reflexes. No such result was given by nerve tissue, muscle, liver, or milk. The hormone-like substance is soluble in water, but not in alcohol or ether, and is dialyzable. It is fairly stable but destroyed by brief boiling. Given orally, the same results were obtained more gradually. The clinical possibilities in nervous diseases are discussed.—*E. V. Lynn.*

10210. HALPERT, BÉLA, MILTON T. HANKE, and GEORGE M. CURTIS. The problem of sodium salicylate excretion in the bile. *Jour. Clin. Investigation* 9(2): 359-362. 1930.—Three patients, 2 with drainage tubes in the common hepatic duct following cholecystectomy, and 1 with a cholesystostomy, were given a single dose of Na salicylate (20 mgm. per kgm. of body weight), and the bile and urine collected for a period of from 12 to 64 hrs. following the administration. The data obtained indicate that the urinary tract is the principal route of elimination, and that salicylate does not appear in the bile, following oral administration of a medicinal dose to patients with diseases of the biliary system. These observations are in accord with data obtained in healthy rabbits.—*Authors' summary.*

10211. HANDOVSKY, H., und P. A. THIESSEN. Röntgenographische Untersuchung von unbehandelten und narkotisierten Nerven. (Vorläufige Mitteilung.) [X-ray studies on untreated and narcotized nerves. Preliminary note.] *Nachrichten Ges. Wiss. Göttingen, Math.-Phys. Kl.* 1930(2): 147-148. 1930.

10212. HARRIS, KENNETH E. Observations upon a histamine-like substance in skin extracts. *Heart* 14(2): 161-176. 4 fig. 1927.—As measured by the depressor effect on the cat, human skin contains an average of 10 mgm. of a histamine-like substance per kgm. of tissue. It is extracted by alcohol. The epidermis contains 6 times as much as the dermis. Frozen or burnt skin contains as much as normal. Some of the histamine-like substance in blister fluid may come from the skin.—*F. Bernheim.*

10213. HEČKO, IVAN. Niektoré pokusy s natriumthiosulfátom. [Some experiments with thiosulphate of sodium.] *Bratislavské Lekárske Listy* 9(5): 299-307. 1929.—For estimation of the therapeutic value of $Na_2S_2O_3$ the position of the S_2O_3 anion in the Hofmeister series was studied. This position differs according to the method used. Measuring the nephelometric effect on a 1/10 dilution of serum, the position of the thiosulphate after 2-4 hrs. is: Na citrate, $NaNO_3$, NaBr, $Na_2S_2O_3$, NaSCN, Na salicylate. After 24-48 hrs. it is: NaCl, $NaNO_3$, Na salicylate, $Na_2S_2O_3$, NaBr, NaSCN. The effect of the salts on viscosity of the serum is displayed in the order observed: after 4-6 hrs. Na_2SO_4, Na salicylate, Na acetate, $Na_2S_2O_3$, NaF, Na formate: after 26-30 hrs. this becomes NaCl, $NaNO_3$ . . . . the position of the NaF and Na formate is interchanged, etc. Other series are given following the influence of the salts on flocculation of serum with ethyl alcohol, heavy metal salts, etc. In particular with $CuSO_4$ and $HgCl_2$, besides formation of complex salts, there is shown a precipitation-preventing influence of the $Na_2S_2O_3$ in parallel with its concentration. The highest possible thiosulphate concentrations must be used if one is to hinder the local precipitation of heavy metals which are administered for therapeutic use in the organism.—*I. Hečko (transl. by C. S. Leonard).*

10214. HENRIQUES, V., und HARALD OKKELS. Histochemische Untersuchungen über die Ablagerungsweise von Gold und Blei innerhalb des Organismus. *Pflüger's Arch. Ges. Physiol.* 225(2/3): 364-371. 6 fig. 1930.—Hydrosols and complex compounds of Pb and Au and ionized Pb salts were injected intraven. into an unstated number of rabbits. The Au compounds showed a tendency to histographic deposition like the corresponding types of Fe compounds. This means that the hydrosol was selectively absorbed in the reticulo-endothelial system, while the complex salts just penetrated the parenchyma cells. After the addition of Na-aurothiosulphate appreciable quantities of Au were found in the proximal convoluted tubules. The Pb compounds in ionized and in the colloidal state exhibited in general

similar relations. Colloidal Pb was deposited mainly in R.E.S., and complex Pb compounds were also found in R.E.S., but preponderately in the parenchyma cells and especially in the kidneys as grains of medium size. Pb acetate was also deposited in the kidney. Pb and Au combinations judged from the kidney findings show a difference in the failure of the Pb compounds to exhibit corresponding depositions. It is difficult to evaluate these results, because Pb salts in the organism easily decompose and become somewhat effaced. Also the lead poisoned animals show pathological symptoms which are likely to influence the deposition picture. With the limitations stated, the results show that in the accumulation of Au and Pb in the parenchymatous organs a selection actually took place which was limited by the type of cell and by the physical-chemical character of the metal compounds.—*Authors' summary (transl. by L. T. Leonard).*

10215. HESS, LEO, und JOSEF FALTITSCHEK. Zur Physiologie der vegetativen Zentren. *Wien. Klin. Wochenschr.* 43(16): 488-492. 1930.—On the basis of experiments by Pick on the point of action of hypnotics the effects of various hypnotics on the autonomic system of man are examined. After the elimination of the mesencephalon by medinal no change of gastric secretion occurs. The blood sugar and blood pressure do not change. After elimination of the cortex cerebri by paraldehyde gastric secretion and blood sugar do not change while the blood pressure falls. These paradoxical observations are consistent with the symptoms of people sick with encephalitis with an anatomical destruction of the mentioned parts of the brain. The autonomic action of the organs can be regulated without the intervention of these parts. Their influence on automatic functions is produced indirectly. The hypotony after paraldehyde is probably analogous to that in ordinary sleep. To explain the indirect action of the autonomic centres on the innervation of the organs special exps. were made. After medinal the vagotropic effect of atropine on the gastric secretion is considerably increased which is also in accordance with the observation on anatomical lesions of these centres in Parkinson's disease. Paraldehyde does not change the atropine action. The epinephrine effect is similarly influenced. The exps. show that the mesencephalon has an influence on the irritability of the sympathetic and parasympathetic nerves. The action of paraldehyde is probably on the cortex cerebri.—*E. Polák.*

10216. HOLTZ, PETER. Einige pharmakologische Wirkungen bestrahlter Eiweisskörper und Eiweissspaltprodukte. *Pflüger's Arch. Ges. Physiol.* 226(4/5): 559-577. 12 fig. 1931.—Solutions of proteins or amino acids were placed in quartz glass or open vessels and were irradiated with a mercury vapor lamp at 20°. Tests were then made for alterations in the rate of flow when these solutions were used for perfusion of frogs, for changes in mean blood pressure when they were injected intravenously in cats anaesthetized with urethane and for changes in motility in surviving smooth muscle preparations. pH was measured and controlled. Irradiation produces vasodilator substances in euglobulin, glycocoll, leucin, histidin and tyrosin. If diluted serum (1 in 100) was irradiated, vasodilator substances were found in the protein free ultrafiltrate. If this was distilled they were found in both distillate and remainder; in the former formaldehyde and acetaldehyde were both found, and both have vasodilator actions; the dry residue gave Pauli's imidazo reaction, and histamine or a similar substance was probably present. The irradiated dilute serum stimulated contraction of the intestine. Irradiated histidin showed properties typical of histamine, which was apparently produced by irradiation.—*H. C. Bazett.*

10217. HÖST, H. F. The influence of insulin on physiologic, alimentary increase of the blood sugar. *Acta Med. Scandinavica* 74(2): 186-190. 1930.—Six tests on 3 healthy individuals proved that insulin influences physiological, alimentary hyperglycemia, and that appropriate quantities of insulin may completely prevent a rise in blood sugar.—*Author's summary.*

10218. HUBBS, CARL L. The high toxicity of nascent oxygen. *Physiol. Zool.* 3(4): 441-460. 1930.—Minnows may be killed by available nascent O in the dilution of 1 part to more than 30,000,000 of water or by only slightly more than 2 units of nascent O to 100,000 parts of their own weight. The effect of nascent O is cumulative. The effect (on minnows) is irreversible beyond the stage of first loss of equilibrium, but is generally reversible until that stage is reached. The least stable nascent-O-yielding chemical tested (ozone) is toxic in much lower concentrations than the most stable one (H_2O_2). Different individuals of the same species show marked variation in their susceptibility to this poison. Some fishes, as the basses and sculpin (Micropterus, Aplites, and Cottus), are much more resistant than the minnows (Cyprinidae). The effect of the nascent O is apparently not on the blood pigments. Fishes are irritated by dilutions of ozone too weak to detect iodimetrically (doubtless less than 0.01 p.p.m.). The symptoms of the poisoning are not those of asphyxiation: there is no lapping at the surface. The effects of nascent O irrespective of its chemical source, are in turn irritation, increased and irregular respiration, loss of equilibrium, wild rolling and dashing, tetanus, death. Death is accompanied by an edematous swelling of the skin.—*Author (courtesy Wistar Bibl. Serv.).*

10219. HUFFMAN, L. D. Metabolic studies in the treatment of polycythemia vera with phenylhydrazine. *Arch. Internal Med.* 39(4): 656-672. 1927.—The chemistry of blood and urine was studied on 4 cases of polycythemia vera kept on a standard diet and treated with phenylhydrazine HCl (0.3 gm. daily by mouth) to reduce erythrocytes and blood volume. Evidence of blood destruction began 7 days after administration of drug, accompanied by increased excretion of N which is accounted for by erythrocyte destruction. Increased N excretion was mainly in the form of urea and some creatine. The changes in the blood consisted in decrease in total N of whole blood proportional to decrease in erythrocytes, increase in non protein N and urea, increase in creatinine in one case. Amino acids were reduced to normal levels by phenylhydrazine. Serum bilirubin increased with slight icterus. Fructose tolerance and phenoltetrachlorphthalein tests showed no hepatic injury. Basal metabolic rate was not affected.—*O. O. Stoland.*

10221. JANSSEN, S., A. LOESER, und P. NOETHER. Ueber die Wirksamkeit der Handelspräparate des Hypophysenvorderlappens. *Arch. Exp. Path. u. Pharmakol.* 151(3/4): 175-187. 3 fig. 1930.—Various German preparations, e.g., Anteglandol, Extr. hypophysis cerebri partis anterioris pro injectione, Extr. hypophysis cerebri feminin., Extr. hypophysis cerebri masculin., Extr. hyp. cerebri pars anterior, Glandular part of hypophysis, Hypotanthin, Hypototal, Praehypophen have no stimulating effect on the ovary of the rat nor any inhibitory action on the ovary of fowl. Most of them lower the blood pressure of cats,—not the case with active preparations.—*H. Graf.*

10222. KANFOR, J. S. Wirkungsmechanismus des Emetins. *Zeitschr. Ges. Exp. Med.* 74(3/4): 385-395. 1930.—Subc. injection of emetine causes lowering of CO_2 tension of alveolar air and increase in excretion of NH_3 in urine, indicating displacement of acid-base balance in the organism, with accumulation of acid ions in the blood and lessening of the alkali reserve. Emetine HCl causes disturbance of balance in the vegetative nervous system through strong stimulation of its parasympathetic section. The duration and depth of these actions are different in individuals and apparently depend upon varying tonus of the vegetative-endocrine system. This important displacement of acid-base balance and the change of tonus in the nervous system

suggest that the therapeutic action of emetine in so many dissimliar diseases can be explained by marked modification of vegetative reactions.—*Author's summary (transl. by E. V. Lynn).*

10223. **KAPLUN, B. J., und J. M. MOREINIS.** Versuch der experimentellen Sensibilisierung gegen Salvarsan, bei Menschen und Tieren. *Acta Dermato-Venereol.* 11(4): 295-304. 1930.—Intradermal injections of neosalvarsan were made on 151 patients, dose 0.1 gm. of a sol. containing 0.15 gm. neosalvarsan to 100 gm. physiological saline. In the cases giving positive results in 7-15 days, some spontaneous reaction could be noticed, following local inflammatory manifestations (infiltrates). In none of the patients who had previously undergone salvarsan treatment was any positive result obtained. Of 84 patients who had never had salvarsan treatment before, positive results were obtained in 9. The appearance in these 9 cases of local dermatoses where the salvarsan administrations had been made, as well as in 3 other cases the appearance of a generalised dermatosis following the ordinary intraven. injections of salvarsan, is considered to prove the sensibility of those individuals to that agent. Corresponding experiments were made on [114] guinea pigs. On the whole, the results, both of these and of the human experiments, confirm the data obtained by Frei, Nathan and Munk. It is evidently possible, in certain cases, by intradermal injection of minimal doses of neosalvarsan to produce, both in human and animal subjects, manifestations of an increased susceptibility to that agent.—*Authors' English summary.*

10224. **KAWAI, HASHIME.** Studies on the hematoporphyrin hemolysis. *Jour. Biochem.* [*Tokyo*] 10(2): 325-350. 1929.

10225. **KEEFER, CHESTER S., K. K. HUANG, and C. S. YANG.** Liver extract, liver ash and iron in the treatment of anemia. *Jour. Clin. Investigation* 9(3): 533-554. 1930.—The response of the blood in anemia was studied in 55 patients, 14 on liver, 10 on liver ash, and 31 on various doses of Fe. Liver extract was of demonstrable value in increasing the regeneration of hemoglobin in some of the obscure nutritional anemias of childhood, in some of the anemias associated with dysentery, hookworm infestation, and pregnancy. In some cases its effect could be enhanced by Fe. Liver ash, when given in amounts equivalent to 300 gm. of whole liver, was of little demonstrable value in increasing hemoglobin regeneration. In some cases there was a slight increase in the reticulocytes, hemoglobin, and erythrocytes, but the results were never as conspicuous as those obtained with liver extract or large doses of Fe. Fe was effective in the treatment of various forms of anemia. Large doses were more effective than small ones. In many instances the effect of Fe exceeded both liver, liver extract, or liver ash, and in some cases a favorable response did not occur until Fe was added. When recovery from the anemias followed either liver extract or Fe there was an increase in the reticulocytes of the circulating blood. The lower the erythrocyte count before treatment, the higher were the reticulocytes at the peak of the rise.

10226. **KISCH, BRUNO, und J. LEIBOWITZ.** Die Beeinflussung der Gewebsatmung durch Omega und durch Chinon. *Biochem. Zeitschr.* 220(1/3): 97-116. 1930.—Respiration of kidney tissues of different species of animals (rats, guinea-pigs, rabbits, field hares, dogs, cats and baboons) was studied with the Warburg apparatus. The kidney from ♀ albino rats, colored rats, guinea pigs, rabbits, cats and dogs had a higher O consumption than did the ♂. The highest values were obtained from gravid animals. Rats, guinea-pigs and rabbits showed small individual differences in respiration; dogs, cats and field hares had considerable variation. In the same nutrient medium at pH 7.4 the order of the quantity of O consumed was as follows: rats > guinea-pigs, field hares > rabbits, dogs > cats. The optimum pH for respiration of kidney tissue of various species was as follows: rats and dogs, 7.1-7.4; cats, 7.4; and rabbits and field hares, 7.7-8.1. More alkaline sols. than these were not studied. Freshly prepared adrenalin in concentrations of 10^{-4} to 10^{-14} when added to the nutrient sol. produced no increase in O consumption. Omega in concentrations of 10^{-4} to 10^{-10}, added to nutrient solutions, increased the O consumption of all species of tissue. Freshly prepared para- and orthoquinone in large doses (10^{-4}-10^{-5}) checked tissue respiration; in smaller doses (10^{-6}-10^{-11}) they increased tissue respiration very markedly. Like concentrations of pyrocatechol and hydroquinone had no apparent action. The order of magnitude of effective concentrations of para- and orthoquinone and of omega is the same on tissue respiration. Both omega and quinone decrease in activity on exposure to light and O.—*Authors' summary (transl.).*

10227. **KLEE, PH., und S. PETROPULIADES.** Bedingungen und Menge der Cholinausscheidung im Harn. *Arch. Exp. Path. u. Pharmakol.* 137(3/4): 129-142. 1928.—Choline in the urine was determined as acetylcholine. The urine was treated with acetone, filtered, and taken up by purified quartz; then acetylchloride was added and the whole warmed to 70° C. for 24 hrs. The acetylcholine formed and quartz were dried and shaken with isotonic Ringer's solution; with this solution isolated frog hearts were perfused. The heart was sensitive to 0.002 gm. in 1000 cc. urine. Choline is continuously excreted, its quantity depending on diet, especially its lecithin content. Diseases with large autolysis of tissues give high quantities in the urine. The content is not increased by oral or intestinal introduction of choline chloride, but a marked increase followed intravenous or rectal administration.—*H. Graf.*

10228. **KLEIN, F., und R. WEISS.** Die Wirkung des Adrenalins auf den respiratorischen Stoffwechsel. *Endokrinol.* 1(4): 264-271. 1928.—Intravenous injection of epinephrine (1-3 gamma per min. per kgm.) raises the respiratory quotient in both lightly and deeply narcotized rabbits, but does not alter heat production. Large doses of epinephrine (0.8 mgm.) raise the R. Q. in deeply narcotized animals. The total metabolism undergoes a decrease in most cases. The metabolic effect of epinephrine, both excitatory and inhibitory, is a complex process which may be resolved into single components. Small physiological doses of epinephrine raise the gaseous metabolism in normal animals and in man. In narcotized animals this rise is lacking both in light and in deep narcosis, obviously because the metabolism is already under the influence of the output of epinephrine accompanying narcosis. The metabolic effect of large doses of epinephrine depends upon the metabolic effect of the mobilized carbohydrate. In fasting animals (low carbohydrate supply) or in deep narcosis (absence of the metabolism raising effect of the carbohydrate) the gaseous metabolism falls; in lightly narcotized well fed animals there is a rise of gaseous metabolism because the metabolism raising effect of the carbohydrate plethora outweighs the original metabolism depressing effect of the large dose of epinephrine. —*Authors' summary (transl. by B. R. Lutz).*

10229. **KÖNIG, WILLY.** Herzarbeit ohne Sauerstoff. III, Mitteilung: Herzmittelwirkung am Warmblüterherzen. *Arch. Exp. Path. u. Pharm.* 127(5/6): 349-365. 12 fig. 1928.—The isolated guinea pig heart was perfused with Ringer's solution at 30-32° C. at which temperatures it will beat several hrs. in the absence of O. Oxygen is an important factor in the action of digipuratum, strophanthin and cardiazol; glucose is not. If either O or glucose is omitted the action of caffeine is markedly reduced; it is entirely prevented when both are omitted. Epinephrine action is similarly altered under these conditions but it lasts 2-5 min. when both O and glucose are absent. Coronary vessel effects are discussed and certain important precautions in this type of work are pointed out. Literature.—*M. Dresbach.*

10230. **KUNIKA, TETSUSABURO.** Über die Pharmakologie des Belladonnins und des Tropins. [In Japanese.] *Nagasaki Igaku Kwai Zasshi* 5: 763-774. 1927.—In the rab-

bit's intestines isolated belladonnine produces, besides paralysis of the parasympathetic endings, muscular stimulation which later passes over into paralysis. In the uterus muscular paralysis is dominant; so that the paralysis of the parasympathetics is demonstrable only with difficulty. Tropine resembles atropine in its effect, though its action is much weaker and displays in the rabbit's intestine as well as in the uterus a parasympathetic paralysis and also a muscle-stimulating effect. The instillation of 10% tropine solution in the eye produces maximum dilation of the pupil.—*Author (courtesy Jap. Jour. Med. Sci.) (transl. by I. H. Pierce).*

10231. **KÜSTNER, HEINZ, und HEINZ SIEDENTOPF. Untersuchungen über die Biologie und Pharmakologie der Placenta. III. Mitteilung. Reaktionsfähigkeit der Placentargefässe auf biologische und pharmakologische Mittel.** *Arch. Gynaekol.* 140(2/3): 298-312. 7 fig. 1930.—By means of special apparatus described, for perfusing the placental vessels, the contraction and dilatation of the vessels was measured in terms of the rate of flow and pressure required to maintain it, contraction diminishing the flow and increasing pressure, while dilatation increased the flow and lowered the pressure. The substances experimented with were 3 products of internal secretion (epinephrine, thyroxin and hormone of the posterior lobe of the hypophysis) and 3 pharmacologic preparations (secale, atropine and caffeine). Epinephrine produced strong contraction; thyroxin had no effect nor had the hormone of the posterior lobe of the hypophysis—a singular fact, in view of the known powerful contracting influence of the last-named hormone on the musculature of the intestine and uterus. Since the placental vessels are not provided with nerves, the effect of epinephrine must be ascribed to direct action on the muscle-cells of the vessels. Secale (ergot) produced brief but distinct contractions; atropine had no effect; caffeine produced a very transitory vascular dilatation. The most important conclusion drawn from these studies is that, since epinephrine contracts and caffeine dilates the placental vessels, and since previous researches have shown such effect to be dependent on the presence of Langley's receptive substance, this substance must be present in the placental vessels.

10232. **KYLIN, ESKIL. Zur Frage der Adrenalinreaktion. [The significance of K and Ca ions for the epinephrine blood sugar reaction.] XIII.** *Zeitschr. Ges. Exp. Med.* 59(1/2): 230-231. 4 fig. 1928.—The influence of epinephrine intraven. before as well as after the intraven. administration of $CaCl_2$ (10 ccm. of 10% sol.) or KCl (2 ccm. of 10% sol.) on the fasting sugar level of patients was studied. Results were variable; a fall occurred in one of 4 groups. Ca or K appeared of little significance in relation to the epinephrine blood sugar changes.—*O. W. Barlow.*

10233. **LAMSON, PAUL D. Results from pharmacological studies of normal and pathological liver conditions.** *Southern Med. Jour.* 23(2): 93-97. 2 fig. 1930.—When there is obstruction to the portal flow, the rise of portal pressure causes an escape of fluids from the vessels, with a resulting acute polycythemia. Upon the ability of the liver to pick out specific substances from the blood stream, and excrete them in the bile depend many liver-function tests. These, however, do not indicate the degree of pathological changes in the liver. That diet plays an important rôle in the prevention and treatment of liver disturbances is shown by the efficacy of Ca to prevent or to correct the fall in blood sugar, the increase in blood guanidine, the tetany and convulsions caused by CCl_4 administered in doses sufficient to produce gross pathological changes in the liver.—*S. N. Blackberg.*

10234. **LÁNCZOS, ANNA. Giftgewöhnung der Nervenfaser.** *Arch. Exp. Path. u. Pharmakol.* 141(3/4): 248-255. 1929.—The sciatic nerves of frogs exhibited recovery in urethane sols. of narcotic threshold concentration, and habituation when the preparation was repeatedly denarcotized in Ringer's fluid and replaced in the urethane sol.; habituation was also attained by preliminary treatment with concentrations below the threshold of narcosis. No recovery or habituation was perceptible in the motor nerve end apparatus—a qualitative difference in addition to the quantitative difference already known.—*Author's summary (transl.).*

10235. **LANWER-DE HAAN, MARTHA. Über Tagesschwankungen der Adrenalinwirkung beim Menschen.** *Zeitschr. Ges. Exp. Med.* 64(3/4): 534-539. 3 fig. 1929.—In the literature concerning the individual sensitivity to adrenaline and the changes of the adrenaline reaction after various diets and remedies, nothing is said of the variability of the adrenaline reaction in the different parts of the day. The author finds that in healthy and ill persons the action of adrenaline (upon the pulse, the blood pressure and the hemogram) is more prompt in the afternoon than in the morning, but in the morning it is more intensive. It is possible that the low starting point in the morning favors the development of a marked reaction. In the variability of its action adrenaline is unique.—*E. Polák.*

10236. **LEFEUVRE, C., et F. GRÉGOIRE. Action de quelques eaux distillées aromatiques sur le coeur isolé.** *Jour. Physiol. et Path. Gén.* 28(4): 833-840. 10 fig. 1930.—Cardiograph tracings show the inhibitory effect of cherry laurel water, orange flower water, dilute HCN, and benzaldehyde, on the perfused frog heart. From comparison it is concluded that the effect of cherry laurel water is due to benzaldehyde while the effect of orange flower water is due to methyl anthranilate. Comparable results were also obtained with the aqueous distillates from mint and from rose leaves.—*W. R. Fearon.*

10237. **LE GOFF, J. M. Cobalt as vaso-dilator.** *Jour. Pharmacol. & Exp. Ther.* 38(1): 1-9. 1930.—The hypodermic injection of 2 to 5 cgm. $CoCl_2$ in 72 human beings varying in age from 15 to 70 yrs. resulted in dilation of the vessels of face and ear in 71 cases. The single exception was a case of splenic anemia. Of 4 tested all showed a fall (10 mm. Hg) in blood pressure 3 min. after injection. A maximum of 122 injections through a period of 3 yrs. failed to develop toxic symptoms. In the dosage used $CoCl_2$ is not toxic to man.—*O. O. Stoland.*

10238. **LEHMANN, FRITZ. Ueber Konstitution und Wirkung. Untersuchungen an aromatischen Fluorverbindungen.** *Arch. Exp. Path. u. Pharmakol.* 130(1/4): 250-255. 1928.—On frogs it was found that toluol and meta-toluidine are rendered more active by F and Cl substitution in the side chain, the F derivatives being more toxic. The trifluortoluol becomes most active by the introduction of the NH_2-group, less so with introduction of NO_2 and COOH groups. The compounds act on the central nervous system; the NH_2 group also has a cardiac paralysing effect. Only the substitution of H by halogens yields depressant products; all substitution products of NH_2 and COOH are excitants. Trifluortoluidine is a useful narcotic for the frog.—*H. Graf.*

10239. **LEHMANN, HANS. Die Wirkung des Kohlenoxyds auf den menschlichen Organismus und ihre Bedeutung für die öffentliche Gesundheitspflege.** *Kleine Mitteil. Mitglieder Ver. Wasser-, Boden- u. Lufthygiene* 6(7/10): 199-215. 1930.—Three points are important in the study of the effect of gaseous impurities in the air of large cities and industrial centers on man: the quantitative determination of CO in the blood stream, the possibility of a reaction of the blood-forming organs to the stimulus of the continuous breathing of gases caused by combustion, the establishment of the effect of such impure air upon the pulmonary system especially of growing children.—*Author's conclusions (transl. by E. K. Borman).*

10240. **LEVY, MAX M., et ERNA M. LEVY. Étude des modifications humorales produites par la sécrétion gastrique déclenchée par l'histamine.** *Arch. Malad. Appar. Diges. et Malad. Nutrit.* 20(2): 137-183. 1930.—Several series of experiments on 16 patients indicate that gastric secretion is subject to individual variations. The quantity of Cl secreted in the form of HCl is variable and by no means in proportion to the total Cl

secreted. Very frequently histamine produces a slight rise in blood urea and an increase in the urea secretion constant which may amount to 44%. These changes seem more frequent and more noticeable in patients in whom the constant was previously high. Histamine may have the opposite action, depressing the constant. The gastric secretion does not modify the alkaline reserve noticeably or consistently. During gastric secretion the plasma and corpuscle Cl may rise as well as fall. The ratio of corpuscle to plasma Cl may increase or decrease, in accordance with variations in the corpuscle Cl. During gastric secretion the threshold of Cl secretion varies in parallel with the blood Cl. Histamine has important effects on diuresis, sometimes producing polyuria, but more frequently oliguria. The relation of alkaline urine to HCl secretion is very irregular; if gastric HCl secretion has any effect on the variations in the pH of the urine, the effect is slight. The 2 other factors which appear to have a preponderating influence on the variations in urinary pH are the urinary Cl debit, and still more the diuresis, which appears to be the principal factor. During the gastric Cl secretion induced by histamine the urinary Cl debit may be either diminished or increased; these variations have no relation to the gastric function. The figures here given indicate that the source of gastric Cl is not the body fluids but probably the tissues.

10241. LÖWENSTEIN, ARNOLD. Über die Entstehung von kleinen melanotischen Knötchen durch Adrenalinzufuhr beim Menschen und beim Kaninchen. [Production of small melanotic nodules in man and rabbits by administration of epinephrine.] *Arch. Dermatol. u. Syph.* 162(1): 180-188. 8 fig. (2 col.) 1930.—Daily instillation of epinephrine into the eye of a man for a long period, and subconjunctival injections into the eye of a rabbit subsequent to instillation produced melanotic nodules. In the rabbit these proved to be subconjunctival melanoblasts as well as accumulations of pigment. These cases are related to the cutaneous and mucosal pigmentation in Addison's disease.

10242. LUKAS, ARTHUR. Über Alkoholausscheidung im Magensaft nach rektaler Alkoholzufuhr. *Arch. Verdauungs-Krankh.* 48(5/6): 332-345. 1930.—The experiments were carried out on fasting patients. The gastric juice was aspirated by stomach tube, measured, and the acid value determined. Immediately afterwards the patient received 300 cc. of alcohol (5%) rectally. Half an hour later the gastric juice was again aspirated, measured, and the acid value determined. The procedure was repeated at intervals of 15 min. until 75 min. after the administration of alcohol. The gastric juice was analyzed for alcohol after distillation, 5 cc. of the pure distillate being used to carry out the analysis. With one exception, in 8 cases alcohol was excreted in the stomach parallel with acid secretion. The quantity excreted was always definite, but quite small, amounting to only a few mgms. It is believed that alcohol is carried by the blood stream to the gland cells of the stomach and from there is excreted into the lumen. This was pointed out some years ago by Bongers, Frouin and Molinier in exps. with dogs given alcohol by rectum.—*R. W. St. Clair.*

10243. MacKAY, MARGARET E. The action of histamine on the motility of different parts of the intestinal tract. *Amer. Jour. Physiol.* 95(3): 527-536. 1930.—Since histamine, which exerts a powerful stimulating action on all smooth muscle with the single known exception of turtle esophagus, may be formed in the intestine, its action on smooth muscle of the alimentary tract is an important problem. Experiments were performed on dogs and cats (number not stated) indicating that histamine when injected intravenously in doses of ¼-½ mgm. in the intact animal activates a quite characteristic motor response in different parts of the intestine. Its effect is most marked in the ileum and decreases towards the duodenum. Local application to a histamine solution to the outside of the gut evokes the same reactions in different portions of the intestine which are seen after intravenous injection of the drug. After paralysis of the parasympathetic nervous system by atropine the characteristic action of histamine on the different parts of the intestine is diminished but not abolished. This inhibitory effect is most marked in the duodenum and least in the ileum. Subcutaneous injection of 1 mgm. of histamine produced no change in the normal rhythm of the intestine. Injection of a solution of histamine containing amounts as large as 50 mgm. of the drug into the lumen of different parts of the intestine did not activate a motor response. Histamine in concentration of 1/100,000 has a greater stimulating action on isolated strips of ileum than on isolated strips of jejunum or duodenum. Atropine does not abolish this effect.

10244. MAJOR, RALPH H., and C. J. WEBER. The relationship of potassium to the depressor effect of liver extract. *Jour. Lab. and Clin. Med.* 15(3): 229-233. 3 fig. 1929.—The active depressor substance in the liver extract with which the authors have worked is not KH_2PO_4, since the liver extract in the doses employed does not contain enough K ions to produce the depressor effect which is obtained. The fall in blood pressure obtained with 20% solutions of KH_2PO_4 is due to what physiologists have long described as "K inhibition" of the heart and has no close analogy with the fall produced by the authors' liver extract. Such sols. of KH_2PO_4 contain at least 20 times as much K as the sols. of liver extract used.—*Author summary.*

10245. MARGINESU, P. Ricerche sperimentali sulla' azione dell'ergosterina irradiata nella profilassi del rachitismo. [Action of irradiated ergosterol in the prophylaxis of rickets.] *Ateneo Parmense* 2(2): 74-92. 1930.—No toxic action was observed from very large doses of ergosterol in 16 young rats (8 on normal diet, 8 on a rachitic diet) intravenously and orally, or in a pregnant rat or her young.

10246. MATTEI, P. Di. Azione della apomorfina e della santonina sui centri iridei. [Action of apomorphine and santonin on the iris.] *Boll. Soc. Ital. Biol. Sperim.* 2(4): 293-297. 1927.—Acts as myotic. Injection of apomorphine into the conjunctival sac caused vomiting in the animals used (dog, cat, rabbit and pigeon) and after injection the pupil no longer reacted to light. Santonin injected into the conjunctival sac of the rabbit (1 gm. per kgm. of body weight) acted as depressant and myotic. From 1 to 1½ gm. per kgm. produced nervous reactions tending to convulsions with dyspnea. Injection of santonin in animals did not affect pupillary reactions.

10247. MAYER, RUDOLF L. Die Ueberempfindlichkeit gegen Körper von Chinonstruktur. *Arch. Derm. u. Syph.* 156(2): 331-334. 4 fig. 1928.—Pellidol and close related azo-coloring matters, certain developers used in photography such as Metol as well as pelt-dyes from the Ursol group have chemical properties in common. The skin irritation of the Pellidol and of azo-coloring matters is closely related. In the skin azo-coloring matter is reduced, with the formation of an aminophenol or Ursol, then these split-products are likewise oxidized to the corresponding quinone. In those people, who are hypersensitive toward quinone, a skin-irritation occurs. The hypersensitivity could be transferred in a passive manner to guinea pigs. The cause of the hypersensitivity is that the quinone, so formed, acts as an antigen toward proteins combined with bodies of the hydro-quinone type. The application is, that one must not give Pellidol to those who are hypersensitive towards Ursol.—*R. L. Mayer (transl. by F. Werner).*

10248. MENCARELLI, LUDOVICO. Iperplasie epiteliali cutanee da ittiolo. [Cutaneous epithelial hyperplasias from ichthyol.] *Arch. Sci. Med.* 54(8): 542-548. 4 fig. 1930.—Repeated pencil strokes with ichthyol were followed in mice and rabbits by marked hyperplasia of cutaneous epithelium, without hyperkeratosis, but sometimes atypical.—*M. Comel.*

10249. MENKE, WILHELM. Versuche zur Abtötung von Paratyphusbacillen im Darm. *Zeitschr. Hyg. und*

Infektionskr. 110(4): 681-696. 1929.—A study was made of the disinfecting properties of iodin-carbon ("Jodkohle" C bearing a deposit of 15% metallic I suspended in physiologic NaCl sol.), Argocarbon (C with 0.5% Ag) and Silargel (AgCl + silicic acid gel). Exps. in vitro showed that the bacteriocidal effect of all these substances was greatly enhanced by acid media and weakened by alkaline. In animal exps. (mice) it was first determined that an acid diet (yoghurt or the A. Adam diet with a milk basis) does not in itself free the intestine of paratyphoid bacilli. Iodin-carbon and Argocarbon, fed with yoghurt or the Adam diet, were toxic to mice and without appreciable effect on the excretion of paratyphoid bacilli. In exps. on 6 mice infected with paratyphoid A bacilli, and fed exclusively on yoghurt (6 controls likewise infected being fed with oats and bread), administration of Silargel freed the feces completely of bacilli. Examination of the organs (2 of the experimental mice having died and the 4 others having been killed for examination) showed the presence of bacilli in liver, spleen and heart, or 2 or 1 of these organs. It is believed that this is the first time that the stools have been rendered non-infective under such circumstances.

10250. MØLLER, EGGERT, CHR. N. J. GRAM, and S. A. SCHOU. Quantitative clinical and spectrophotometrical comparison between natural and synthetic thyroxin. *Acta Med. Scandinavica* 74(1): 85-103. 1930.—Synthetic thyroxin (Hoffmann-La Roche) and natural thyroxin (from Harington's laboratory) gave identical spectrophotometrical curves, had the same I content (65%) and produced the same increase in the basal metabolism of patients with myxedema. The latter effect was studied by means of intravenous injections of 10.5 mgm. of thyroxin. With the synthetic preparation 3 injections were given to 3 patients, with the natural preparation 2 injections to 2 of these same patients. The basal metabolism was followed by frequent determinations during at least 50 days after each injection. The total increases produced in the basal metabolism during this period were identical within the limits of error to be expected from the method. To 3 patients 4 injections were given with another preparation of natural thyroxin (B. D. H.), which proved to be of inferior strength. This result was obtained both by metabolic, chemical and spectrophotometric observations. The preparation contained only 75% thyroxin. The general therapeutic effect of the intravenous injection of large doses of thyroxin was in no way superior to that which could be expected in similar cases to follow the oral administration of the equivalent amount of desiccated thyroid gland substance, divided into small doses to be given daily for the same length of time during which the metabolic effect of the intravenous injections persisted, i.e., about 60 days. The description given by Plummer, Boothby and others of the changes in the basal metabolism during the weeks following the intravenous injection of large doses of thyroxin in myxedematous patients is on the whole confirmed, although the declining parts of the curves did not show any marked tendency to be of logarithmic shape. The description by Abderhalden and Rossner of the spectrophotometrical curve common for natural and synthetic thyroxin is confirmed.—*Authors' summary.*

10251. MOLTENI, P. Sull'influenza dell'adrenalina, della pilocarpina e dell'atropina sul riflesso patellare. [Effect of epinephrine, pilocarpine and atropine on the patellar reflex.] *Arch. Sci. Biol.* 13(3/4): 407-420. 7 fig. 1929.—Graphic records were made of the reflex after intravenous injection of the drugs. The diminished responses following epinephrine, pilocarpine and atropine cannot be cited in favor of the view that skeletal muscle tonus is maintained through the autonomic system. On the other hand, the diminution induced by epinephrine is probably due to anemia of reflex centers. The same result, obtained by pilocarpine in high dosage, may be due to a lowered excitability of the same centers. The diminution or temporary disappearance of the reflex after atropine is caused by stimulation of the cerebral cortex and its inhibitory centers.—*A. Jappelli.*

10252. MOORE, ROBERT A., SAMUEL GOLDSTEIN, and AARON CANOWITZ. The mitochondria in acute experimental nephrosis due to mercuric chloride. *Arch. Path.* 8(6): 930-937. 4 fig. 1929.—Retention of N in the blood occurs in nephrosis due to $HgCl_2$ in the white rat before there are demonstrable changes in the morphology of the kidney. There are definite changes in the cytoplasm and nucleus of the proximal convoluted tubule before the mitochondria show any qualitative change. It is suggested that $HgCl_2$ produces nephrosis by adsorption on the surface of the mitochondria, "poisoning" the interface and later killing the cell.—*Authors' summary.*

10253. MORELLE, JEAN. Étude radiographique de l'influence de l'ergostérol irradié sur la reconsolidation des fractures expérimentales. (Note préliminaire.) *Rev. Belge Sci. Méd.* 2(3): 226-228. 2 pl. 1930.—A fibula was fractured in each of 18 ♂ rats, of which 1 group received 0.001 mgm. ergosterol daily, a 2nd 0.1 mgm. (about 3-4 times the human therapeutic dose) and the 3rd 2-4 mgm. The fracture knit more rapidly in the rats receiving 0.1 mgm. than in the controls; the larger doses produced an abnormally exuberant callus.

10254. MOTOMURA, SUSUMU. Über den Einfluss verschiedener Pharmaka auf die experimentelle Anaphylaxie. [Japanese.] *Osaka Igaku Kwai Zasshi* 26: 2072-2122. 1927.—Intracardiac injection of 0.1 cc. of horse serum into guinea-pigs weighing 200-300 gm., which had two weeks previously received a subc. injection of 0.01 cc. of the same serum, causes the development of typical anaphylactic shock. In order to study their effect on this shock, various drugs were injected intraperitoneally 1 hr. before the 2nd dose. Pilocarpine and physostigmine always inhibit the anaphylactic shock, epinephrine is uncertain in action and atropine produces no effect. Cardiac tonics, such as digalen, camphor, hexeton, caffeine and diuretin, also produce some inhibition of the anaphylaxis; with the first 3 the action is lasting, but with the latter 2, it is transient. Narcotics, such as urethane, morphine and alcohol, also inhibit the anaphylaxis, urethane having the most powerful action, morphine slightly less and alcohol least. Quinine, lobeline and "secacornin" also act as anti-anaphylactics. Barium chloride always inhibits the anaphylaxis, $MgSO_4$ is uncertain in its effects and $CaCl_2$ and $Na_2S_2O_3$ have no action. Physiological salt solution and hypertonic solution of glucose always act as anti-anaphylactics, but gum solution does not, while with gelatin solution the effect is uncertain. Peptone, casein, "electrargol" and lecithin sometimes show marked inhibition of the anaphylaxis. Pituitrin acts as an anti-anaphylactic in female but not in male animals. Thyraden, a preparation obtained from the thyroid gland, has an inhibitory effect. Spermatin, a preparation from the testis, and oöphormin, an ovarian preparation, increase the anaphylactic shock. Biosterin, a preparation containing vitamin A, and paranutrin, a preparation containing vitamin B, always show marked inhibition.—*Author (courtesy Japanese Jour. Med. Sci.) (transl. by J. M. Watt).*

10255. NARAHARA, K. Experimentelle Untersuchung über den Hautzucker. II. Der Zuckergehalt der Haut unter Beeinflussung von verschiedenen Medikamenten. [In Japanese.] *Japanese Jour. Dermatol. & Urol.* 30 (11): 1113-1128. [German summary, 117-118.] 1930.—In a previous communication [Journal Kumamoto Med. Soc.] it had been shown: (1) that the average cutaneous blood sugar value in the rabbit is about 111 mgm.%, the blood sugar value about 105 mgm. %; (2) that the values of both blood and skin sugar may vary in parallel with nutritional conditions; and (3) that the same parallelism obtains in the blood and skin sugar changes following oral or intravenous administration of sugar. In this study the substances (autonomic drugs, various ions, heavy metals, insulin, salvarsan and

$NaNO_2$) were given either intravenously, intramuscularly or subcutaneously. Epinephrine, pilocarpine, eserine and diuretin raised the skin sugar; ergotoxin varied; atropine was indefinite in its effects. Of the various ions, Ca always and Na frequently raised the skin sugar content; K and Mg were indefinite in effect. Novasurol generally raised, electrargol depressed the skin sugar; the effect of "casbis" was not clearly recognized. The salvarsan preparation "neo-ehramisol" and $NaNO_2$ tended to raise the skin sugar; insulin depressed it to the minimum. The blood sugar and skin sugar curves were almost always parallel under the administration of any drug, except in the agonal stages of death from the drug; then the blood sugar rose abruptly and the skin sugar fell to the minimum.—*From author's summary (transl.).*

10256. OKA, NOBUWO. Über die Ascaridolvergiftung. *Japanese Jour. Med. Sci. IV. Pharmacol.* 3(3): 201-233. 3 pl. 1929.—The ascaridol fraction is the constituent of oil of chenopodium detrimental to the hearing organ. Principal changes are: degeneration in cells of the spiral ganglia and nerves and in the auditory cells. The first point of attack of the poison is the spiral ganglion cell; the Nissl bodies are changed as to staining qualities, size and number. None of these effects were demonstrable with the terpene fraction of oil of chenopodium. A histologically detailed comparison is made between the effects of detonation and of ascaridol upon the organ of Corti and related structures. The degenerative changes in spiral ganglia cells may be demonstrated in intoxicated animals that still show the Preyer ear muscle reflex.—*Author's summary (transl. by W. N. Berg).*

[In German, with English summary.] *Acta Dermato-Venereol.* 11(3): 245-253. 1930.—Alimentary hyperglycemia prevented symptoms of intolerance to arsenobenzol in 15 clinical cases, probably owing to chemical or nervous action on the liver.

10258. OTA, M[ASAO]. Étude expérimentale sur le venin de la punaise des lits. [In Japanese.] *Japanese Jour. Dermatol. & Urol.* 30(9): 966-976. [French summary, 100-102.] 1 fig. 1930.—Intraperitoneal injection of an aqueous extract of bedbugs in saline solution proved capable, in suitable dosage, of killing a mouse (immediately or after some hrs.), and of producing vomiting followed by death in ½ day in a dog. The active material was not affected by heating for ½ hr. to 65°, or by pepsin-HCl or by trypsin, but seemed to be diminished by heating for ½ hr. to 80° or even 70°, and by ultraviolet irradiation. This aqueous extract, intracutaneously injected, produced intense erythema, urticaria and itching in most men; subjects, however, differed greatly, some not reacting at all. Alcoholic extracts, even in large amounts, did not kill a mouse; they produced erythema, urticaria and itching in men, but less intense than when caused by aqueous extracts. Ethereal extract produced neither death in animals nor itching in men, but merely a faint and transient erythema. The aqueous extract had no hemolytic action on the erythrocytes of the sheep, rabbit, white rat or man. Fixation, using the aqueous extract as antigen, was obtained with the serum of rabbits which had been sensitized by this antigen, but not with the serum of unsensitized rabbits. Human sera gave a positive or doubtful reaction in 3 cases out of 10. Antibody seemed capable of neutralizing the fatal toxicity of the antigen. Mice injected with aqueous extract in more than fatal dosage survived if treated with immune serum; it did not, however, prevent the production of the cutaneous reaction in man.—*From author's summary (transl.).*

10259. PAASCH, G., und H. REINWEIN. Studien über Gewebsatmung. V. Mitteilung: Der Einfluss von Thyroxin, Adrenalin und Insulin auf den Sauerstoffverbrauch von überlebenden Rattenzwerchfell. *Biochem. Zeitschr.* 211(4/6): 468-474. 1929.—No increase in rate was found, with any of these substances, for O consumption in vitro. Such positive effects as have been reported by others are regarded as secondary to changes in permeability of the cells.—*H. S. Hopkins.*

Coeur, Vaisseaux et Sang.* 23(5): 333-338. 1930.—The authors believe that epinephrine in intravenous injection shows a predominant vagotropic stage, manifested by a retarding of the rhythm, accompanied by auriculo-ventricular dissociation.

10261. POLLAND, W. SCOTT. The effect of atropine upon gastric secretion after histamine stimulation. *Jour. Clin. Investigation* 9(2): 319-332. 1930.—Curves are presented comparing the course of gastric secretion after histamine with that after histamine and atropine [in 7 patients]. The volume of secretion, titratable acidity, concentration of pepsin, total output of acid and total output of pepsin have been studied. Atropine dissociates the normal response to histamine, producing a marked decrease in the volume of secretion, and in the concentration and total output of pepsin. The titratable acidity rises as a result of the only slight inhibitory effect of atropine on the total output of acid. The results suggest that water, acid and pepsin may have different mechanisms of secretion.—*Author's summary.*

S. Wells.*

10270. **RIDLEY, H. N. On the action of the poison of the Upas-tree (Antiaris toxicaria Bl.).** *Jour. Trop. Med. & Hyg.* 33(13): 185-186. 1930.—The pure latex, which is sticky and probably absorbed slowly, injected into the abdominal wall of a dog, produced no permanent ill effect. Mixed with a decoction of *Strychnos ovalifolia*, it formed a fluid drug which, injected as before into a dog, produced hard, rapid breathing, vomiting and convulsion; the dog was killed. In toads injection of the latex produced slight convulsions, violent peristalsis, first acceleration and later retardation of the heart-beat, local contraction of capillaries and death.

10271. **RIES, FERD A., and EUGENE U. STILL. On the toxicity of purified bile preparations. II. The neuromuscular system.** *Amer. Jour. Physiol.* 91(2): 609-617. 1930.—Experiments on frogs indicate that bile salts are only slightly toxic to muscle and do not materially affect conduction through the nerve fiber, and that the neuro-muscular junction and the reflex centers of the cord are the structures most susceptible to such toxic effects.

10272. **ROBBINS, BENJAMIN H. A proteolytic enzyme in ficin, the anthelmintic principle of leche de Higueron.** *Jour. Biol. Chem.* 87(2): 251-257. 1 fig. 1930.—Leche de Higueron (the latex of *Ficus laurifolia* according to Hall and Augustine, 1929, and to Chandler, 1928; of *F. glabrata*, according to Paez, 1914-1915) produces on ascaris immersed in it small blisters or ulcers which perforate and cause the death of the ascaris. The active component of the latex was extracted by precipitation from aqueous solution by 3 parts of acetone or 5 parts of alcohol. The purified protein so obtained, named ficin, contained free amino groups, 16% N, 1.05% S. The ficin was exposed to various temp. between 40° and 97° C. for 5 min., cooled, and incubated at 35°, ascaricidal activity being determined; the preparations heated to 75° or above had been inactivated. Coagulated egg albumin was digested and casein hydrolyzed by ficin. Ficin is destroyed in 1½ hrs. at pH 2-3, hence largely destroyed by passage through the stomach; is active over the range pH 4-8.5. Evidently, the active principle is a proteolytic enzyme of the trypsin type, different from trypsin and papain; possibly more than one enzyme is concerned.

10273. **RONDONI, PIETRO. L'azione inibente della digitonina sullo sviluppo dell'adenocarcinoma del topo. [Inhibiting action of digitonin on the development of adenocarcinoma of the mouse.]** *Boll. Soc. Ital. Biol. Sperim.* 5(5): 722-723. 1930.—Treatment with digitonin is followed by a slackening of the development of adenocarcinoma in mice, the rate of growth of the neoplasm diminishing by half as compared with control animals. More marked necrosis, and activation of the reticulo-endothelial system were observed. The author thinks that a union between digitonin and cholesterol in vivo is responsible for the observed delay in development of adenocarcinoma in mice.—*M. Comel.*

10274. **SAITO, J. Über hautreizenden Giftstoff eines japanischen Giftschmetterlings, Euproctis flava Bremer. [In Japanese.]** *Japanese Jour. Dermatol. & Urol.* 30(3): 230-243. [German summary, 29-30.] 1 pl. 1930.—The hairs of the caterpillars produce an itching, twitching dermatitis; whether by mechanical or toxic irritation has been disputed. A water- and glycerol-soluble poison can be extracted from the hairs which possesses the same properties as *E. flava*. The poison is soluble in normal salt sol. and glycerol, but not in ether, $CHCl_3$, alcohol, benzene or toluene. The method for extracting the venom is described. If the venom sol. is applied to the skin of the forearm no reaction is observed; but if a drop be placed on the skin and then brought under the epidermis by means of a fine needle, a red swelling appears in 30 min. which after 6 to 7 hrs. becomes more pronounced and extensive, and after 24 hrs. is spread over the whole forearm and accompanied by lymphangitis. The venom is fairly stable to heat, gives no protein reaction, and also no hemolytic action on the red blood-cells of rabbits and sheep. The lethal dose is very great with *Rana japonica*, mouse, and rabbit. It causes no albuminuria, but appears to have certain diuretic properties. It showed an increase in blood-pressure in the rabbit, but no effect upon the respiration. —*Author's summary (transl. by L. W. Butz)*.

10275. **SAKEL, M. Theorie der Sucht.** *Zeitschr. Ges. Neurol. u. Psychiatr.* 129(3/4): 639-646. 1930.—An attempt is made to advance a cellular-hormonal interpretation of somatic morphine addiction. Exceedingly favorable results in stopping the abstinence phenomena by the use of insulin as the chief therapeutic agent are also reported.—*Author's summary (transl. by W. Malamud)*.

10276. **SANTESSON, C. G. Kupferstudien.** *Skand. Arch. Physiol.* 61(1/3): 79-112. 7 fig. 6 pl. 1931.—CuS was injected subcut. in rabbits in doses of 1.1-1.35 gm. Seven to 8 doses were given in a period of 40-55 days. The animals were killed with $CHCl_3$ and sections taken for microscopic study. Local necrosis was produced with granules of CuS in phagocytes. There was sulphide necrosis in the large and small intestines and some in the liver. The lungs in 2 cases were hyperemic and showed hepatization. With $CuSO_4$ injections there was a more rapid subacute poisoning. The pathology was similar to that of CuS. One rabbit was injected with Bi salicylate (0.4 gm. subcut. for 16 days), with results similar to that for Cu.—*R. P. Herwick.*

10277. **SCHEINER, GEORGE. The influence of adrenaline on the activity of the kidneys.** *Acad. Tcheque Sci. Bull. Internat. Rés. Trav. Présentés Cl. Sci. Mat. Nat. et Méd.* 28: 174-181. 1927.—To ascertain the influence of adrenaline on the activity of the kidneys, the Strauss water test (1000 ccm. of liquid at once) and the diuretic test (100 ccm. of weak tea and 50 ccm. milk given every hour) were employed. The subject was requested to urinate every hr. Adrenaline was introduced either subcut. (1 mgm.) or intraven. (0.05 mgm.) with the same effect. In the Strauss water test adrenaline stimulated, in the diuretic test it slackened the diuresis. The variation of the blood-pressure after the injection had no connection with the diuretic effect. The cases of nephroses gave the same effect as healthy persons. The injection had no influence on the excretion of NaCl and of N compounds.—*H. Přibram.*

10278. **SCHIFF, ALICE. Die durch Vigantol erzeugbaren Gefässwandveränderungen und ihre Rückbildungsfähigkeit im Tierversuch.** *Virchow's Arch. Path. Anat. u. Physiol.* 278(1): 62-83. 6 fig. 1930.—Vigantol may produce certain changes in the media of blood vessels, namely, degeneration, proliferation and calcification. The aorta suffers the greatest changes. The carotids are affected with almost equal frequency, the iliacs somewhat less often. In cats the coronaries and the pulmonary arteries are the most frequent visceral vessels; the kidney vessels are somewhat less frequently affected. In rabbits the renal arteries are most frequently affected. (10 out of 14 cases.) The arteries of the brain and liver were never involved and only once was a small branch of the splenic artery affected. There is no definite parallelism between the amount of vigantol and the degree of change produced. At the beginning of the disease there occurs a swelling of the substance between the

fibres. Superimposed on this swelling there occurs a change in the course of the elastic fibres, a granular disintegration of the swollen substance, a disintegration of the characteristic fibres, calcification, a proliferation of histiocytes, finally also small hemorrhages. Eventually there may be secondary thickening of the intima and collections of cells in the adventitia. The changes which are observed may be divided into 2 definite arrangements, a band form and a focal form. The expected retrogression of these changes in the blood vessels could not be demonstrated with certainty. More pronounced formation of granulation tissue could not be found in animals in which vigantol administration had been long discontinued than in those that were still receiving the preparation. When very small amounts of vigantol are administered there occurs, likewise, no healing. On the contrary, in these animals the damage due to vigantol develops further and eventually may lead to death. The clinical manifestations of disease and the severity of the changes in the blood vessels do not run parallel. Thus, it is possible to find severe calcification in the blood vessels in animals that are clinically well.—*B. Kramer.*

10279. **SCHMIDT, A. A. Über die Wirkung des Insulins in Abhängigkeit von der Anwendungsmethode.** *Zeitschr. Ges. Exp. Med.* 73(5/6): 599-607. 1930.—Only 1 of 15 rabbits went into convulsions following a single intraven. injection of 3 units of insulin per kgm., a transient hypoglycemia being observed. The same dose given subc. produces an intensive hypoglycemia accompanied in most cases by convulsions. The same dose given intraven. in divided intermittent fractions through an hr. produces a more pronounced hypoglycemia with an increased incidence of convulsions than a single injection. It is inferred that the tissues remove and inactivate insulin given intraven. so that little reaches the muscles. When given subc., a more proportionate assimilation by the tissues takes place, so that an increased activity in the muscles follows.—*F. E. Bischoff.*

10280. **SCHOENE, GERHARD. Zur Wirkung der Muzilaginosa.** *Arch. Exp. Path. u. Pharmakol.* 131(3/4): 186-199. 1928.—Gum arabic, tubera salep, tragacanth, carrageen, gelatina animalis, radix colombo, radix althaeae, agar-agar, lichen islandicus, sago and rice lengthen the reflex time in the spinal frog; gum arabic, althaea and colombo root were most active. The effect cannot be attributed to increased viscosity; it is due to the adsorption of HCl on the colloidal particles. Titrations of mixtures of the mucilages and acid show that 10% of HCl is chemically bound while 40% is loosely fixed. The actual acidity of the mucilage-acid mixture is only 5-15% that of the original.—*H. Graf.*

10281. **SCHREIBER, G. L'azione del calcio sulle ghiandole endocrine. [Ca action on endocrine glands.]** *Arch. Sci. Biol.* 13(1/2): 127-157. 1 pl. 2 fig. 1929.—Since P. Enriques and his collaborators showed an endocrine interrelation in the changes following bone fractures, and suggested that Ca salts discharged into the circulation by osteolysis can exert a stimulating influence on the endocrine system, $CaCl_2$ was injected into guinea pigs. Weight increase in the thymus of young animals and histological evidence of overactivity as after a fracture were observed. The weight of the adrenal glands was diminished in young subjects, increased in old ones; histologically the volume increase could be seen in reticular zone of the cortex. The thyroid showed also a slight increase.—*A. Jappelli.*

10282. **SCHÜBEL, K., und W. TESCHENDORF. Zur Methodik der Uterus pharmakologie.** *Arch. Exp. Path. u. Pharmakol.* 128(1/2): 82-98. 8 fig. 1928.—After the uterus of rabbits and cats was filled with 10% Iodipin oil, its movements were registered roentgenologically by a series of pictures and graphically by means of Marey's tambour recording from the tube where the contrast liquid was introduced. No surgical operative procedure was necessary. The experimental animals (cats) were anesthetized for 24-30 hrs. with ether, lying on the back, untied, between two bags of sand. This narcosis had no influence on the movements of the uterus. Roentgenological registration is superior to the graphic, as very often graphic registration fails, particularly when one portion of the uterus contracts and another relaxes. The close agreement of the uterine movements with those of the intestine is quite visible in the roentgen picture. Changes in the position of the entire organ are plainly visible, the tonus and the rabbit's uterus demonstrated well the course of the peristaltic waves. The pharmacologic examination of a uterus filled with oil or a Ringer solution represents a method which permits the study of the processes of pregnancy and abortion. This method on account of its great simplicity is suitable for lecture demonstration.—*Authors' summary (transl. by F. R. Greenbaum).*

10283. **SCHULZ, HUGO. Vorlesungen über Wirkung und Anwendung der deutschen Arzneipflanzen.** 2nd ed. 310p. Georg Thieme: Leipzig, 1929. 14 M.—The author gives brief descriptions of German medicinal plants and of their drug products. Histology is not included. The approach is more from the point of view of pharmacology than from that of pharmacognosy. Extensive data are included on folk medicine. About 40 pages of botanical origins with common synonyms are appended.—*R. W. St. Clair.*

10284. **SCHÜTZ, ERICH. Beitrag zur Kenntnis der Herzwirkung des Cardiazols.** *Zeitschr. Ges. Exp. Med.* 65(1/2): 147-152. 3 fig. 1929.—Cardiazol on the Langendorff heart of the dog and cat produced increased force and frequency of heart-beat, especially if the heart had been weakened. Just after the injection of cardiazol there was a decrease in the height of the heart's contractions due to the washing out of the heart in the Langendorff preparation. Two cases of "spontaneous" cardiac delirium were restored to strong, regular beats by cardiazol; but electrically induced delirium cordis was not affected.—*E. Schütz (transl. by Clyde Brooks).*

10285. **SCHWARZ, H. Calendula.** *Heil- und Gewürz-Pflanzen* 12(1): 21-22. 1929.—Note on pharmacological use of flowers and leaves of *Calendula officinalis.*

10286. **SECHI, ELIO. Sulla resistenza del gonococco isolato dall'individuo sottoposto alla cura acridinica (tripaflavina). [Resistance of the gonococcus isolated from a patient during acridin (trypaflavin) treatment.]** *Gior. Ital. Derm. e Sifil.* 71(6): 2080-2089. 1930.—The maximum and minimum limits of resistance of the gonococcus to trypaflavin having been established, 8 injections were performed (3 in a wk.) on the patient, the resistance in vitro being tested 48 hrs. after each injection. The resistance was the same after the last injection as at the beginning of the treatment. Trypaflavin has neither direct nor indirect effect upon the gonococcus. Its action is simply antiseptic.—*Author's summary (transl.).*

10287. **SEEL, HANS. Pharmakologische Untersuchungen über natürliches und synthetisches Menthol.** *Arch. Exp. Path. u. Pharmakol.* 122(5/6): 338-353. 1927.—Natural optically active menthol was compared with various isomeric synthetic menthols among which were Isomenthol, Neomenthol and Neo-Isomenthol. There was a difference only in the degree of pharmacological effect. The nature of the action was similar. The toxic symptoms consisted of a transient increase of irritability, increased respiratory and pulse frequency, gradually increasing paralysis, ataxia, disappearance of all reflexes and finally tetanic convulsions. The natural optically active menthol is about twice as toxic as the synthetic inactive preparations with the exception of Neo-isomenthol which possesses approximately the same toxicity as the natural menthol. The menthol of commerce does not always have a uniform composition. The toxicity of menthols in general is slight. With the frog's heart it requires high concentrations to produce diastolic standstill. The hemolytic effect is very slight with the exception of Neo-isomenthol. Injury to the blood or irritation of the kidneys was not observed. The synthetic inactive menthol cannot be differentiated

from the natural menthol of commerce by odor or taste. On the other hand, Iso-neo and Neo-isomenthol have a more or less camphor like odor and taste. With reference to the medical application of crystallized, synthetic, inactive menthol of a melting point of 35-36° C., it is less poisonous than some of the natural menthols of commerce.—*Author's summary (transl. by B. Kramer).*

10288. **SEHESTEDT, HANS. Über den Einfluss von Somnifen auf den Gasstoffwechsel von Kindern.** *Zeitschr. Ges. Exp. Med.* 72(3/4): 514-521. 3 fig. 1930.—Studies on 12 children aged 5-15 yrs.

10289. **SIEDENTOPF, HEINZ. Untersuchungen über die Wirkung des Thyroxins in der Schwangerschaft.** *Monatsschr. Geburtsh. u. Gynäkol.* 85(5/6): 325-341. 1930.—The author established the limit of non-injurious dosage of thyroxin as 2 injections each of 2-3 cc. for the normal non-pregnant guinea-pig. In 2 pregnant guinea-pigs, 2 successive injections of 2 and 3 cc. respectively induced slightly premature birth, the young being born alive and capable of growth. In 4 other pregnant guinea-pigs, single injections each of 2 cc. thyroxin induced subnormal growth in the fetuses, which were born alive but much under normal weight. Observations on 16 clinical pre-natal cases revealed no pathologic change in the fetal heart action from a dose of 1-2 cc. thyroxin injected into the mother. Repeated daily intravenous injections of 1-2 cc. thyroxin in cases of edema of pregnancy in most cases produced no important change in water excretion or reduction of edema, indicating that subnormal function of the thyroid is at least not a frequent cause of edema of pregnancy. Doses of 2 cc. thyroxin given every other day for 2 mos. before parturition to 17 pregnant women with narrow pelves were followed by the birth of normal children weighing and measuring slightly less on the average (200 gm. and 1.7 cm. less) than the average children born of untreated mothers.

10290. **SIMONIN, CAMILLE. L'empoisonnement alcoolique aigu de l'adulte et de l'enfant. Coefficient d'imbibition alcoolique mortelle. (2e Mémoire.)** *Jour. Physiol. Path. Gén.* 38(3): 624-631. 1930.—The toxic dose of alcohol for the guinea pig is about 8.5 cc. per kgm. body-weight. Death is never very rapid, and may occur 12 hrs. after ingestion. In delayed poisoning the alcohol content of the blood at the time of death may be low, showing the power of the tissues to abstract alcohol. The action of insulin on blood-sugar appears to be unaffected by the presence or absence of alcohol. —*W. R. Fearon.*

10291. **SORGE, G. Modificazioni delle soglie renali durante la terapia insulinica nei diabetici. [Variations of renal threshold during insulin treatment of diabetes.]** *Boll. Soc. Ital. Biol. Sperim.* 5(5): 762-764. 1930.—Rise of renal threshold values for glucose, water and chloride was observed.—*M. Comel.*

10292. **SPAGNOL, G. Fixierung von Suspensionskolloiden durch anästhesierende und narkotische Stoffe.** *Arch. Exp. Pathol. u. Pharmakol.* 137(3/4): 250-256. 1 fig. 1928.—After intraven. injection of some colloidal dye suspensions, they are found to be fixed in the skin and underlying tissues about the area of application of chloroform. Only those colloids bearing electronegative charges are so fixed, and the greater the degree of diffusibility of the colloid the more complete the fixation. The phenomenon is due to a change of the capillaries, allowing the colloid to pass out of the vascular system and accumulate especially in the reticuloendothelial network. A possible therapeutic application of the observations is suggested.—*C. Reynolds.*

10293. **SSENTJURIN, B. S. Über den Einfluss des Adrenalins auf den Eiweissstoffwechsel isolierter Organe.** *Arch. Exp. Pathol. u. Pharmakol.* 133(3/4): 233-241. 1928.—The non-protein and protein N contents of a Ringer-Locke sol. after perfusion through the blood vessels of the testicle of the bull, or the liver or kidney of the cat, were determined by Borodin's method. On continued perfusion the non-protein N gradually decreased. The protein N usually decreased during the first 2 hrs., but after 3-4 hrs. an increase was characteristic, the total quantity being always greater than the quantity of non-protein N. Epinephrine (1 in 1 million to 1 in 100 million) increased the non-protein N 79% on the average, but had no constant effect on the protein N. The epinephrine effect is believed to be due to an increase in protein metabolism of the tissues. —*B. R. Lutz.*

10294. **STANLEY, ROBERT F., and DONALD A. LAIRD. The effects of massive doses of sodium bromide on mental and motor control in normal human beings.** *Med. Rev. of Rev.* 36(12): 753-756. 1930.—For the purposes of experimentation, 10 Colgate University students were tested every Wednesday and Friday afternoon for a period of 10 wks. At noon on each test day, the subjects took orally either 75 grains NaBr or a control dose of the same amount of NaCl. Preliminary tests giving central tendencies for a group rather than individual differences show that amounts of NaBr as used in the experiment have most marked and significant effects upon such mental functions as lag of attention, speed of addition, and speed of cancellation, in the normal individual. The effects on motor coordination are not as marked or uniform. Respiration and cardiovascular functions show some slight effects. This preliminary experimentation should give encouragement for a systematic study of the effects of NaBr in a wider range of test functions and under different dosages with normal individuals as well as for individual differences. The present preliminary experiments suggest that beneficial effects observed in mental patients from the use of massive doses of NaBr are associated to a large extent with the speeding up of mental functions and to some extent with improved motor co-ordination.

10295. **[STEPPUN, O. A.]** СТЕППУН, О. А. О препаратах наперстянки, их стандартизации и стандартных титрах. **[Digitalis preparations, their assay and biological effectiveness.]** [German summary.] Труды Научного Химико-Фармацевтического Института (*Trans. Sci. Chem. Pharmaceut. Inst.* [*Moscow*]) 13: 80-98. 1926.—A historical review of the development of the chemistry of digitalis is given. The advantages of the galenic over the so-called pure or purified glucosides are depicted, and also the disadvantages which come from incomplete dosage. The possibilities of quantitative estimation by bioassay are described, and assay methods are treated critically. The author sees great advantages in the use of purified and pharmacologically controlled preparations which, however, keep to the features of the galenic preparations (Digipuratum etc.). The best known preparations were classified and critically treated, and the corresponding Russian preparations are given.—*Author's summary (transl.).*

10296. **[STEPPUN, O. A.]** СТЕППУН, О. А. О биологических методах определения ценности лекарственных средств. **[Biological methods of determining the value of certain drugs.]** Труды Научного Химико-Фармацевтического Института (*Trans. Sci. 10297. **[STEPPUN, O. A.]** СТЕППУН, О. А. О биологической оценке сердечных средств. **[Biological value of cardiac drugs.]** [German summary.] Труды Научного Химико-Фармацевтического Института (*Trans. Sci. Chem. Pharmaceut. Inst.* [*Moscow*]) 13: 106-109. 1926.—General principles of assay of cardiac drugs are treated and the assay methods are critically discussed.

10298. **STOLL, ARTHUR; SYDNEY SMITH, and G. M. TIMMIS; and H. H. DALE. The alkaloids of ergot.** *Lancet* 219(5595): 1148-1150. 1930.—Polemic. The letters deal with the questions of whether ergotoxin and ergotamine exist together, or independently, in ergot of rye; and which is the active principle. Dale deplores the lack of clinical experience with the former.

10299. **TERAUCHI, KOJIRO. Über die sogenannte Kurarewirkung verschiedener Substanzen.** *Tohoku Jour.*

Exp. Med. 12(5/6): 505-513. 1929.—Of the so-called curare-like substances $MgSO_4$, tetraethyl-ammonium chloride, piperidine, coniine, sparteine, nicotine, lobeline, camphor and Mokuren-curare paralyse the motor nerve-endings while pyridine, quinoline, strophanthin, saponin and Tetrodon-poison paralyse the motor axons and not the nerve-endings. It is possible that there are other curare-like substances with the same action as the latter group.—*Author's conclusion (transl. by J. W. Watt).*

10300. **TESTONI, P. Azione dell acetato di tallio sul sangue.** [Action of thallium acetate on the blood.] *Bull. e Atti R. Accad. Med. Roma* 56(1): 3. 1930.—Because thallium acetate poisoning, and even the use of thallium acetate as a depilatory, produced a marked pallor lasting for some time, the question arose if Tl produces blood changes similar to those induced by Pb. Systematic research showed that acute or chronic thallium acetate poisoning produced no lesions and no basophilic granulations in the erythrocytes.

10301. **TESTONI, P. Il tallio. 2. Acetato talloso ed ematoporfirina.** [Thallium. 2. Thallium acetate and hematoporphyrin.] *Bull. e Atti R. Accad. Med. Roma* 56(8/9): 217-224. 1930.—To learn whether the numerous analogies between Tl and Pb extend to the production of hematoporphyrinuria by Tl as by Pb, therapeutic and toxic doses of Tl acetate were given to dogs and rabbits (number not stated) but no trace of hematoporphyrin was found in the urine.—*Author's summary (transl.).*

10302. **TRACHTENBERG, F. Ephedrinwirkung auf die Magen-Darmtätigkeit.** *Arch. Verdauungs-Krankh.* 48(1/2): 69-95. 4 fig. 1930.—In observations on 27 patients, presenting various types of gastro-intestinal disorders, the action of ephedrine on the tract was found to correspond to its action in animal experiments. The immediate effect, as shown by the fluoroscope, is a stimulation of gastric motility lasting 8-10 min. This is followed by inhibition, with prolongation of the time for emptying and for passage through the intestine, an effect which lasts 3-4 hrs. Gastric acidity is not usually affected, and when changed at all is lowered. The concentration of neutral chloride in the secretion is increased. The particular cells and innervation involved in this function of secretion of neutral chloride are not known. As atropine also causes an increase in this secretion it might be assumed that the sympathetic provides augmentor, the parasympathetic, inhibitor fibers to the cells responsible.—*H. S. Wells.*

10304. **TROPEA, UGO. L'estratto biglandolare associato di timo-ipofisi (tymophysin) e l'azione di esso sulle contrazioni dell'utero.** [The combined biglandular thymo-hypophyseal extract and its action on uterine contractions.] *Riv. Ostetr. e Ginecol. Prat.* 11(7): 21-41; (8): 9-22. 12 fig. 1929.—Experiments on the isolated and in situ uterus of the guinea pig, using a Pugliese apparatus and a combined extract of thymus and hypophysis, gave in a high percentage of cases positive results as well in clinical as in experimental tests. In women the preparation is capable of exciting typical physiological contractions of almost normal rhythm and excursion and continuing for various periods. From this it is concluded that the biglandular extract of Temeswary can be regarded as specific in overcoming inertia in the relaxed period,—a circumstance that makes for optimum service in that contingency.—*U. Tropea (transl. by J. G. Edwards).*

10305. **TRUFFI, G. Azione biologica dell'acetato di tallio.** [Biological action of thallium acetate.] *Arch. Sci. Biol.* 13(3/4): 271-319. 4 pl. 1929.—Alopecia from thallium acetate must be referred to a direct influence upon the hair, not through the neuroendocrine apparatus. In fact, the neuroendocrine lesions are not characteristic of thallium; they are caused also by other poisons, which do not produce falling of hair. Moreover, these lesions fail in case of small doses of thallium acetate, even sufficient to cause alopecia. Hence thallium cannot be considered as an endocrino-sympathetic poison. —*A. Jappelli.*

10306. **TU, TSUNGMING. Über die Wirkung von Exzitantien auf Atemmechanik und Gaswechsel des normalen Menschen.** *Arch. Exp. Path. u. Pharmakol.* 125(1/2): 1-15. 1927.—The Zuntz-Geppert method was used. Lobelin caused increases in lung ventilation and basal metabolism not to be accounted for by altered respiratory mechanics alone. Ephedrine had an effect similar to that of lobelin, but of longer duration. Caffeine caused increased lung ventilation as with lobelin and ephedrine, without appreciably influencing basal values. Strychnin after several hours caused increases in respiration and metabolism barely above experimental error. Hexeton increased lung ventilation by 10-20% without altering basal values. Cardiazol caused slight increases in lung ventilation and basal metabolism partly due to the pain of the intramuscular injection. Atropine was without effect.—*Author's summary (transl. by W. N. Berg).*

10307. **UFLAND, J. M. Über die Wirkung starker Phenollösungen auf die sensorischen Rückenmarkelemente des Frosches.** *Arch. Exp. Path. u. Pharmakol.* 122: 247-256. 1927.—Local application of 4% phenol sol. to the sensory elements of the spinal cord of spinal frogs did not kill the elements, but increased their irritability.—*J. C. Munch.*

10308. **VIALE, G., L. NAPOLEONI, e D. ROSSELLI. Eliminazione di acido ossalico nella glicosuria florizinica.** [Oxalic acid elimination in phlorhizin glycosuria.] *Arch. Sci. Biol.* 13(1/2): 206-210. 1929.—Phlorhizin, administered to dogs fed meat or mixed diet, has no definite action on oxalic acid output. This is easy to understand, because phlorhizin has chiefly a renal action. Nevertheless phlorhizin can sometimes injure the pancreas; in that case, as in adrenalin glycosuria and in experimental diabetes, the urinary output of oxalic acid may be increased.—*A. Jappelli.*

10309. **VIOLLE, P.-L., et A. GIBERTON. Propriétés anti-toxiques du calcium vis-à-vis du sulfate de sparteine.** *Compt. Rend. Acad. Sci.* [*Paris*] 188(18): 1181-1182. 1929.—Guinea pigs treated with mixtures of $CaCl_2$ and lethal doses of sparteine sulphate survived indefinitely. Those treated with sparteine sulphate followed by doses of $CaCl_2$ also survived indefinitely. In animals previously treated with Ca death following administration of the alkaloid was delayed. Experiments with diphtheria toxin proved negative.

10310. **WEESE, H. Digitalisverbrauch und Digitaliswirkung im Warmblüter. I. Die Effectivdosen verschiedener Digitalisglykoside für das Herz.** *Arch. Exp. Path. u. Pharmakol.* 135(3/4): 228-244. 1928.—Cats' hearts were separately perfused (Starling heart-lung method) with a known amount of digitoxin, strophanthin and scillaren, in a definite quantity of blood-Tyrode mixture. The minimal fatal doses (contractions recorded graphically) were compared with those by the Hatcher-Brody method. 4.5-9% of the glucoside is fixed in the heart, the rest being bound in other organs and tissues, as no excretion can occur in the perfusion experiments. The heart can detoxicate a glucoside solution completely (hydrolysis). This does not occur appreciably in blood, scillaren excepted. The reaction velocity in the heart is a simple, linear function of glucoside concentration.—*M. Dresbach.*

10311. **WEIL, ARTHUR. Veränderungen in dem histologischen Bilde und dem Lipoidaufbau des Zentralnervensystems in der Äthernarkose.** *Pflüger's Arch. Ges. Physiol.* 223(3): 351-363. 7 fig. 1929.—In 4 out of 5 etherized dogs and 3 out of 5 etherized cats, diffuse staining of the Nissl bodies was observed in the cells of the anterior horn of the spinal cord, also a distension of the sheath of the spinal cord due to increase of fluid within it. The lipins were determined by the Maclean method of fractional extraction. The acetone-soluble fractions showed increase, the

alcohol soluble fractions decrease, and the lipins precipitable from the alcohol extract were diminished, only the lecithin fraction showing a relative increase. The changes in the lipin content of the gray substance were more marked than those in the white substance or the spinal cord, corresponding to the double or treble physiologic increase in metabolism in the cortex. The morphologic and chemical changes began about the 2nd hr. and quickly reached a maximum, remaining almost constant between the 3rd and 5th hr.

10312. WINOGRADOW, A. P. Zur Pharmakologie des Pilokarpins. *Arch. Exp. Path. u. Pharmakol.* 122(3/4): 207-210. 1927.—Tests were conducted to determine the effect of pilocarpine upon the rate of flow of bile from a Pawlow-fistula dog. In general no effect was observed during digestion, although a rhythmic flow was obtained before or after meal time. The action was due to an effect upon the autonomic nervous system, similar to the action upon the urinary bladder.—*J. C. Munch.*

10313. WYMAN, LELAND C., and BRENTON R. LUTZ. The action of adrenaline and certain drugs on the isolated holothurian cloaca. *Jour. Exp. Zool.* 57(3): 441-453. 1930.—The effects of adrenaline and of certain drugs on the isolated cloaca of *Cucumaria frondosa* and *Stichopus moebii* were determined. The effective dose of adrenaline chloride produced a progressive decrease in tone, amplitude, and rate, with a final cessation of beat. Adrenaline caused a marked acceleration of the beat of the intestinal blood vessel of *Stichopus*. Adrenaline, therefore, has both inhibitory and excitatory effects on invertebrate tissues. Physostigmine, nicotine, and histamine produced a progressive increase in tone and a decrease in amplitude and rate. Curare, strychnine, and atropine produced a cessation of beat, usually preceded by a decrease in amplitude and rate. The tone was unaffected or slightly decreased by these drugs. Pilocarpine was generally ineffective. Adrenaline produced the typical inhibitory effect after doses of curare or histamine, but was ineffective following physostigmine or nicotine. Following cocaine, ergotoxine, or an ineffective dose of atropine there was evidence of a reversal of the inhibitory effect of adrenaline. Cocaine and ergotoxine produced no visible effect when used alone.—*Authors (courtesy Wistar Bibl. Serv.).*

10316. BENTIVOGLIO, G. L'anemia di Biermer nell'infanzia. *Haematologica 1. Arch.* 10(6): 531-564. 1 pl., 3 fig. 1929.—Author describes 2 cases of cryptogenetic pernicious anemia in infants (5-6 mos.) characterized by augmentation of hemoglobin index and megalocytosis. One case was cured with liver medication, the other was fatal after 48 hrs. While leukopenia and thrombocytopenia may be lacking in infantile pernicious anemia, they usually appear later, although to a less degree than in the adult. The paper has an exhaustive literature on infantile hematology, especially as regards grave anemias.—*N. A. Michels.*

10317. BIEDERMANN, W., und K. HÖFER. Ergebnisse der Züchtung von menschlichem Xanthomgewebe in vitro. *Arch. Exp. Zellforsch. Bes. Gewebezücht.* (*Explantation*) 10(1): 93-100. 8 fig. 1930.—Material from a case of xanthomatosis of the dura mater and bones of the skull (in Christian's syndrome) was explanted on chicken plasma followed by transfer to a base of chicken plasma and chick embryo extract 10: 1, and covered with a mixture of patient's serum, chicken plasma, and chick embryo extract 5: 1. The cultures lived 18 days. Mature cells showed double refraction similar to xanthoma cells in histologic section. Their form, type of movement, presence of numerous long, fine cell processes, as well as an almost homogeneous sphere in the neighborhood of the nucleus, pointed to a reticulo-endothelial origin. The latent period of 5-7 days showed by the culture was relatively short when compared to embryonic tissue on the one hand and mature on the other; it indicates a highly potent group of cells.

10318. BÜCHNER, FRANZ. Die Histologie der peptischen Veränderungen und ihrer Beziehungen zum Magenkarzinom. [Histology of peptic changes and their relation to stomach carcinoma.] 2 pl., 37 fig. Gustav Fischer: Jena, 1927. Pr. 12 M.

10319. BURRUANO, CALOGERO. Rapporto dell'ovaio e della tromba con l'appendice. [Relations between ovary, tube and appendix.] *Monitore Zool. Ital.* 40 (11/12): 538-540. 1930.—In 35% of 160 women observed, the appendix had a decidedly pelvic position. In 40 cases its length was more than 10 cm., in 16 cases more than 14 cm. In such cases the appendix was touching the right ovary and tube. Ligaments directly connecting tube and appendix were never found. The association of diseases of appendix and tube is to be explained generally by the contact between the 2 organs, not by the existence of special connections of lymphatic vessels or of ligaments and plicae.—*E. Padoa.*

10320. CAPECCHI, EGISTO. Teratoma mammario in sede inguinopubica. [Mammary teratoma in the inguinopubic region.] *Arch. Ital. Chir.* 26(4): 485-496. 12 fig. 1930.—The tumor, in a man of 68, had within 3 yrs. become considerably enlarged and secreted a fluid resembling fetid milk. Histologic examination on removal indicated its nature as a mammary teratoma.

10321. CATTANEO, L. Sul comportamento dei megacariociti nell'infezione vaccinica sperimentale. [Behavior of megakaryocytes in experimental vaccinal infection.] *Haematologica 1. Arch.* 11(4): 257-266. 5 fig. 1930.—Neurovaccine (from the Institute Pasteur of Athens) inoculated into rabbits produced an intense megakaryocytosis characterized by the appearance of young forms (polykaryocytes). With inoculations of dermovaccine only a slight increase of megakaryocytes was noted.—*N. A. Michels.*

10322. CHIARI, HERMANN. Zur Pathologie und Histologie der generalisierten Torulose. (Blastomykose.) *Arch. Dermatol. u. Syph.* 162(2): 422-441. 10 fig. 1930.—The author reports the autopsy findings on the patient (reported by Urbach and Zach) who died from bronchopneumonia caused by pneumococcus. Small abscesses in the kidney containing almost exclusively eosinophils, leucocytes and yeast cells were interpreted as the earliest blastomycetic lesions. This destruction of the tissue was soon followed by proliferation of fixed connective tissue cells predominantly from the adventitia of the smaller

arteries. The giant cells form from adventitial elements by amitotic division. Thus a granulation tissue is formed from young epithelioid-like fibroblasts and giant cells, with a few lymphocytes and plasma cells. Yeasts are found in these granulomas almost entirely in giant cells or large mononuclear cells. The form and size of the yeast cells vary and degenerated forms are evident. This granulomatous tissue may then be replaced by a larger abscess preceded by a sort of caseation. The oldest lesions, as those in the lung, mouth, stomach and intestine, as well as in the lymph nodes, no longer show characteristic granulation tissue elements. These are replaced by tissue rich in collagen fibers with a few lymphocytes and plasma cells. A few yeast cells can still be seen. A large amount of iron-containing pigment is present and some of the veins are dilated. The authors believe that the various stages in the tissue reaction depend on the variability of local allergy and anergy.—*S. W. Becker.*

10323. CHORONSHITZKY (CHORĄŻYCKI), B. Sr. Topographie und Mechanik der Gaumenmandeln. *Monatsschr. Ohrenheilk. u. Laryngo-Rhinol.* 63(10): 1058-1074. 31 fig. 1929.—From review of literature and his own clinical experience, the author concludes that the tonsillar anlage, when embedded in a deep tonsillar recess, develops under heightened positive pressure, which causes the peritonsillar tissue to form in concentric layers, constituting the rudiments of the capsule of the deeply buried tonsil. The pedunculated tonsil has no capsule. Pathologically the 2 types of tonsils, the pedunculated and the capsulated, are distinguished by the fact that the former can of course have no subcapsular abscess and discharges the tonsillar content much more easily than the encapsulated. A bilobate tonsil is the result of the persistence of the embryonic intratonsillar fold. The capsule covers the upper and under surfaces of the tonsil like a cap, which extends over the fossa supratonsillaris also; the edge of the cap divides the mucosa of the lateral pharyngeal wall from the mucosa covering the tonsillar recess ("Mandelbucht"). Owing to this cap the enucleated tonsil in frontal section has the outline of an arabic 6, on the back of which a subcapsular abscess forms an excrescence of varying size.

10324. CONDORELLI, LUIGI. Sull'importanza delle lesione infiammatorie del plesso sottoepicardico dell' orecchietta destra nella patogenesi di alcune turbe del ritmo cardiaco. [Inflammatory reactions of the subepicardial plexus of the right atrium in the pathogenesis of some disturbances of cardiac rhythm.] *Riforma Med.* 44(21): 613-616. 4 fig. 1928.—A study of the distribution and topography of the subepicardial ganglia in the region surrounding the sulcus terminalis. In clinical cases with auricular fibrillation and nodal rhythm, there exist extensive inflammatory lesions circumscribed by these ganglia. Possibly some disturbances of cardiac rhythm, especially auricular, can result from anatomical alterations in the ganglia.—*L. Condorelli (transl. by J. G. Edwards).*

10325. COOKE, W. E., and C. F. HILL. Microscopical studies in pernicious anaemia. I. *Jour. Roy. Microsc. Soc.* 50(4): 427-432. 2 pl. 1930.—The erythroblast, a term comprising normoblasts, megaloblasts, and microblasts, may be found in the blood stream as a first or second generation cell. The first generation cells undergo mitosis and are found in various stages from the resting nucleus to late telophase and daughter cells. After reconstruction the second generation nucleus disappears by simple karyolysis, or by pycnosis and karyolysis, or by pycnosis, karyorrhexis and karyolysis combined. Nuclear remains in the form of Howell-Jolly bodies and Cabot's rings, and a third type—that of irregularly shaped particles of chromatin—are described. Chemical inadequacy of the red cells is suggested by the active phagocytosis of them by the reticulo-endothelial cells of the marrow, the almost complete absence of rouleaux formation, the frequency of auto-agglutination and the so-called endoglobular degeneration or vacuolation. By dark ground illumination the red cells in pernicious anemia are not all bi-concave; some appear biconvex and some almost globular in shape.—*W. E. Cooke.*

10326. CROSETTI, L. Il reperto ematologico negli stati di ipertiroidismo. [Hematological findings in states of hyperthyroidism.] *Haematologica 1. Arch.* 11(4): 283-320. 1930.—In 19 cases of Basedow's disease the author found augmented regeneration of red cells, the ratio of circulating reticulocytes (granulophilocytes) varying from 14 to 35%. Globular values of the red cells and of hemoglobin percentage were likewise above normal. Aside from an increase of lymphocytes, the white blood cells showed no appreciable variations. Augmented erythropoiesis is ascribed to increased thyroid secretion by virtue of which the maturation of the red cells is hastened. This thesis was substantiated by obtaining reticulocyte increases in 2 pernicious anemia patients (10-32%, 45-75%), in rabbits (25-47%), and in guinea pigs (25-36%) with injections of thyroxin. The paper cites an extensive literature on reticulocytes (granulophilocytes).—*N. A. Michels.*

10328. DALLA PALMA, M. Sul significato delle ombre nucleari di Gumprecht. [Significance of the nuclear shadows of Gumprecht.] *Haematologica 1. Arch.* 11(4): 321-336. 1930.—Morphologically altered leucocytes known as nuclear shadows, nuclear remains, free nuclei, smudges, plaques reticulées, the diameters of which varied from 25 to 35μ, do not exist as such in the circulating blood. Their presence in smears is due to artifact, i.e., traumatic manipulation. Varying from 0 to 8% in normal smears, the structures are of greater frequency in blood of myeloid leukemia; in lymphatic leukemia they may be encountered in ratios of 18-70%. The intense production and destruction of leucocytes characterizing leukemia accounts for these high percentages in the sense that excessive maturation as well as excessive immaturity may be the cause of the lability of the leucocytes in question. Production of these leucocytic variations may be avoided by the large drop method commonly used in the study of malarial parasites. With this method smudges are entirely absent or reduced to a minimum. In ordinary smears nuclear shadows have no diagnostic or prognostic value except when they are extremely numerous; they then indicate abnormal lability of the leucocytes and the existence of grave hemopoietic lesions.—*N. A. Michels.*

10329. DOLFINI, G. Lo stadio precollageno dell'organizzazione del trombo (con due microfotografie). [Precollagen stage in the organization of a thrombus.] *Arch. Sci. Med.* 53(2): 120-128. 2 fig. 1929.—In the process of thrombus organization the collagen fibers are preceded by a reticulum, of variable rate of development, which may be demonstrated by the Del Rio Hortega method for reticular fibers, and partly also by the Mallory method for connective tissue. This precollagenous reticulum is closely related to the newly formed capillaries.—*G. Dolfini (transl. by A. M. Sala).*

10330. ERDMANN, R. Änderungen morphologischer, histologischer und physiologischer Natur des späteren Tumorträgers durch die verschiedenen Methoden, experimentellen Krebs zu erzeugen. *Zeitschr. Krebsforsch.* 32 (6): 628-631. 1930.—The author studied the changes in rats (susceptible and resistant strains) injected with tumor-producing filtrate used in earlier experiments. Immediately after the inoculation splenic congestion with occasional hepatic congestion occurred, and within a week a pronounced hemosiderosis in the spleen, and at times deposition of fat, especially in the peripheral follicles. The kidneys showed similar degenerative changes. Liver changes were more specific: innumerable and persistent areas of minute necrosis, which were the more numerous the less the tendency to tumor development. In addition there were proliferation of the

tissues of Glisson's capsule and infiltration (of endothelial cells?). The significant difference between potentially tumorous animals and resistant ones was the persistence in the latter of a far-reaching mobilization of the reticulo-endothelial system throughout the liver. In animals with tumors appearing in vitamin deficiency, in addition to marked degenerative changes (largely of fat deposition), there was localized overgrowth of the reticulo-endothelial system, which may be the site of later tumor development.—*H. E. Eggers.*

10331. ERDMANN, R. Wirkung von tumorzellfreiem und tumorzellhaltigem Material auf Leber, Milz und Niere von konstitutionell geeigneten und ungeeigneten Tieren. *Zeitschr. Krebsforsch.* 33(3): 189-218. 1 fig. 1930(1931).—In exceptional cases the author reports successful sarcoma induction by injection of cell-free material. After such injection, a common type of reaction was observed in liver, spleen, and kidney. In the liver there was a marked hyperplasia of the reticulo-endothelial cells, large accumulations of them being formed, with later necrosis in these areas. Later, there were hyperplasia of Glisson's capsule and cellular infiltration. In the spleen there were first congestion, later fatty degeneration of the pulp and occasional necrosis of the follicular cells. In the kidney there were early cloudy swelling, epithelial desquamation, and at times eosinophilic infiltration. With the appearance of tumor the changes of the reticulo-endothelial system, except the necrosis, disappeared; the difference between susceptible and insusceptible animals seemed to rest in the persistence in the latter of a stimulated reticulo-endothelial system which prevented the accumulation in sufficient amount of the tumor-causing agent; an additional indication of this reticulo-endothelial alteration was found in the form of fat deposition in the Kupffer cells of the livers of resistant animals, which was followed by extensive fatty infiltration of the parenchymatous cells. The author regards splenic changes as of essentially the same character. It was impossible to determine whether the renal changes were merely of accessory or of primary importance.—*H. E. Eggers.*

10332. FONTANA, LUIGI. A proposito dei cosidetti "eritroconti" descritti da Schilling nell'anemia perniciosa. [So-called "erythrocontes" described by Schilling in pernicious anaemia.] *Arch. Sci. Med.* 53(2): 65-78. 1929.—In many cases studied to control Schilling's findings both in cases of pernicious anemia and other blood diseases, the author noted that a distinction, which Schilling fails to make, must be made between certain extremely rare tiny rods, demonstrable in the dry preparation with the Giemsa stain, and other much less rare tiny rods demonstrable with basophilic vital stains (Nile blue). At any rate both kinds of rods must be considered as peculiar formations of the pathologic globular structure and not pathognomonic for any blood disease, being met only inconstantly in pernicious anemia and, on the other hand, being present in other blood conditions. Therefore the author denies these erythrocontes the importance attributed to them by Schilling.—*L. Fontana (transl. by A. M. Sala).*

10334. HENSCHEN, FOLKE. Die Reaktion der fixen Mesenchymzellen bei der Entzündung. *Acta Path. et Microbiol. Scand. Suppl.* 5: 10-13. 1930.—Fibroblasts are transformed into epithelioid cells and giant cells. Regeneration of fat cells and mesothelial cells is reported. Different reactions of the histiocytes as well as the development of the histiocytes into epithelioid cells, giant cells and monocytes are treated. Changes of endothelial cells of the blood vessels are pointed out.—*M. Silberberg.*

10335. HILL, L. G. Lymphangioma of the abdomen. *Lancet* 219(5591): 897-899. 2 fig. 1930.—Case in boy 8 yrs. of age. Microscopic findings are given and attempts to explain the origin of such tumors are reviewed.

10336. INNES, J. R. M. Arterio-sclerotic kidney (primary contracted type) and secondary contracted kidney in the dog. *Vet. Rec.* [*London*] 10(31): 698-702. 6 fig. 1930.—Of 2 cases of nephritis described, one shows extreme sclerosis of the arteries in the boundary zone and the cortex, with much calcification and abundant connective tissue proliferation. The other shows atrophy of the cortex with but little of the normal structure of the cortex remaining. The arteries were well defined and showed no traces of sclerosis.—*L. W. Goss.*

10337. JONESCU, P. Über das Vorkommen von Geschwulstzellen im strömenden Blut von Tieren mit Impftumoren. *Zeitschr. Krebsforsch.* 33(3): 264-280. 1 fig. 1930.—In mice with successfully implanted sarcoma, the author found in blood withdrawn from the heart of living animals, with great frequency, atypical cells with lipoidal granulations, and with very frequently mitotic nuclei, the counterparts of which were absent in normal animals. Inasmuch as tumor massage increased their numbers, Jonescu interprets them as detached tumor cells which have entered the circulation.—*H. E. Eggers.*

10338. KELLER, HANS. Beitrag zum qualitativen Blutbild bei der Tuberkulose. 29p. Dissertation, Univ. Zürich, 1928.—Comparison of 12 cases having a good prognosis and showing a proliferative reaction with 12 cases (confirmed at autopsy) having an exudative reaction and intestinal involvement revealed that the neutrophiles undergo toxic changes in tuberculosis as in other infectious diseases. Nuclear changes, i.e., reduction in the number of segments and clumping of the chromatin, were found in all cases but were more prevalent in the exudative type. The principal cytoplasmic change, "toxic granulation," occurred in relatively few cells in proliferative cases but was present in a large percentage of the neutrophiles in exudative cases. This "toxic granulation," characterized by the presence of large, irregular, deeply staining granules in the cytoplasm of the neutrophiles, had a direct relationship with the type and severity of the cases.—*C. M. Goss.*

10339. KIMURA, REN. Züchtung von Hühnermyxosarkom in vitro. II. *Arch. Exp. Zellforsch. Bes. Gewebezücht.* (*Explantation*) 10(2): 174-177. 1930.—The author grew 142 generations of myxosarcoma in only 27 of which was it necessary to add heart tissue. Much mucus appeared in vivo and in vitro; after the 7th passage there was thickening in the middle of the culture, central necrosis, vacuole formation, and increase in refraction which decreased with the addition of heart tissue or after the 40th generation; the later generations produced as much mucus in vivo, however, as did the earlier more mucous generations, or as in chick to chick transfer. In the 1st generation the growth of round cells was pronounced, and they could phagocytose carmine or trypan blue; they did not appear after 1-2 generations, but reappeared for 2-3 generations after any addition of heart tissue. Spindle cells appeared in the 1st generation, were not phagocytic, and soon constituted the entire culture; there were no demonstrable differences between these cells and fibroblasts except that the former underwent pronounced vacuole formation and growth ceased in time; mitotic figures were observed sometimes. Chickens (13) on whom the cultures were tested for malignancy usually died within a month. No metastases to internal organs occurred. No relation between malignancy of tissue and its round cells was found.

10340. KLINKE, K., und H. PAHLKE. Dysostosis cleidocranialis. Bericht über 2 Fälle. *Arch. Kinderheilk.* 91(1/2): 46-54. 8 fig. 1930.—The authors describe 2 cases and suggest that in the fully developed aspect of the disease it is a question of a primary disturbance of membranous ossification, analogous to osteogenesis imperfecta, which is limited to bones formed from cartilage. Close relationship to the hypophyseal "geographical" skull, or to fibrous osteitis, cannot be demonstrated. Anti-rhachitic measures are useless.—*A. Ehrenfried.*

10341. KRAUS, ERIK JOHANNES, und OLGA TRAUBE. Über die Bedeutung der basophilen Zellen der menschlichen Hypophyse. *Virchow's Arch. Path. Anat. u. Physiol.* 268(2): 315-345. 1928.—Examination for basophil cell content of the anterior lobe in 232 human hypophyses from normal and pathological subjects indicated that normal persons with medium constitution (mesosthenic habitus) in normal nutritional conditions possess a certain constant quantity of basophil cells. A marked increase of these cells occurs in normal persons with hypersthenic habitus, and also in patients suffering from diseases which primarily affect hypersthenic constitutions (high blood pressure, vascular sclerosis, renal cirrhosis, etc.). Most asthenics (persons with diabetes mellitus, pulmonary tuberculosis, or cancer cachexia) and patients with hypoplastic, atrophic, or badly damaged adrenals show a diminution in basophil content. Cases showing large adrenals with much doubly refracting lipoid generally have an increase in basophil cells. These facts warrant the hypothesis that there are certain relations between the basophil cells of the hypophysis and the constitutional type, as well as blood pressure and the amount of blood or adrenal cholesterol. —*P. Vonwiller.*

10342. MACDONALD, G., A. P. PIGGOT, and F. W. GILDER (with note on the chemical examination of the lung by FRANCIS ARNALL, and E. A. RUDGE). Two cases of acute silicosis, with a suggested theory of causation. *Lancet* 219(5590): 846-848. 1930.—Two fatal instances of pulmonary silicosis are reported in women employed in packing a cleaning powder containing ground silica. The deaths occurred after a relatively short period of exposure to the substance and from this the authors constructed the theory that the alkali in the cleaning powder hastened the process by converting the silica, when taken into the lungs, into a colloidal state. Chemical analysis of the lungs of the patients for the silica content and the state in which it existed indicated "the presence in the affected lung of: combined silica, free silicic acid derived from combined silica, and original crystalline silica. The amount of iron in the lung was sufficient to satisfy the combined silica present." These findings seem to prove the theory advanced. Cleaning powders containing alkali, soaps and silica, should be made by the wet process. The presence of alkali dust is always dangerous when combined with that of silica.—*C. J. Bucher.*

10343. MARINESCO, G., und STATE DRAGANESCO. Beiträge zum Studium der primären infektiösen diffusen Neuritiden. (Versuche einer Entgliederung der Gruppe der Polyneuritiden.) *Deutsche Zeitschr. Nervenheilk.* 112 (1/3): 44-74. 11 fig. 1930.—A woman, aged 45 yrs., presented for several months the symptoms of polyneuritis with ataxia. Histological examination revealed inflammation of the peripheral nerves, muscles, and suprarenal capsules, and to a lesser degree of the central nervous system. This case belongs to the group of diffuse infectious polyneuritides—produced by a neurotropic virus—which are true "septineuritides" (Nicolau). Pathologic study of 10 rabbits, intracerebrally inoculated with a neurovaccine, showed extension of the virus into the peripheral nerves.—*G. Marinesco (transl. by A. M. Woodruff).*

10344. MAUSS, KARL. Zahnanomalien bei Idioten und Imbezillen. *Deutsche Zahnärztl. Wochenschr.* 32 (18): 1-31. 1929.—The incidence of hypoplasia of the enamel, true (primary) diastema, abnormally high palatine arch, and certain types of malocclusion in 130 imbeciles and 51 idiots was 4 or 5 times greater than in the general population. The incidence of certain other anomalies was also high. The author concludes that these anomalies are to be regarded as stigmata of degeneracy etiologically ascribable to disturbance of the endocrine apparatus, particularly the hypophysis and parathyroids.—*S. W. Chase.*

10346. MEISSEL, M. N. Über die Wirkung der Röntgen- und Radiumstrahlen auf das Nervengewebe. I. Reaktion der Hautnerven bei Röntgen- und Radiumbestrahlung. *Virchow's Arch. Path. Anat. u. Physiol.* 276(1): 77-94. 7 fig. 1930.—Irradiation of the skin of 35 white mice produced hyperplasia of the epithelium and enlargement of the subepithelial and intraepithelial nerves. Changes in the hair follicles were connected with important changes in the hair nerve apparatus. The circular fibers of this apparatus proliferated and new fibers penetrated the epithelium until the proliferating portion of the nerve was completely reconstructed. The palisade portion of the apparatus did not proliferate, but sometimes degenerated. Atypical epithelial growths, bulbous or cystic, were all supplied with nerves which penetrated between the individual cyst cells. A large number of Langerhans' cells were observed in the proliferated epithelium. Similar changes were observed in connective tissue which had undergone inflammatory changes. Subcutaneous application of radon produced marked changes in the tissues and nerves with degeneration at the periphery of the radon tube. Large doses of radon caused tissue necrosis, similar to that caused by nerve section, with rapidly following regeneration. The epithelial layers regenerating the injured region are supplied with nerves which turn in the direction of the new growth and run to its end. Frequently, excessive nerve supply in the regenerating epithelium gives an atypical appearance to the nerve net and branches of the intraepithelial nerves. Mitoses occurred most frequently in new-formed epithelium in the neighborhood of the nerve. After irradiation, regenerating nerves in the region of necrosis often exhibited irregular branching. The peripheral nerve formations are to be regarded as structures in unstable equilibrium which change with the changes in the surrounding tissues.

10347. MENDOLA, GIUSEPPE, e GIUSEPPE AGOSTA. Lesioni articolari sperimentali da "Monilia tropicalis Castellani." *Arch. ed Atti Soc. Ital. Chir.* 34: 645-653. 1927[1928]; also in *Morgagni* 70(15): 721-741. 1928.—Injection of this organism into the articular cavity in guinea pigs caused an acute reaction lasting 10-15 days, and a permanent functional disturbance. Miliary nodules were found consisting of lymphoid cells, leucocytes and new vascular spaces between the lining and the underlying tissue; also, proliferation of the endothelial cells of the synovia and formation of new tissue here, which may protrude into the sac. The lesion is exudative and proliferative, causing thickening and adhesions. There is intense proliferation of the cartilage cells, necrosis, then new growth of the epiphyseal bone, and a proliferative reaction distally between muscle and tendon. Injection into the vascular stream may kill the animal in 20 days.—*E. A. Baumgartner.*

10348. MENON, T. BHASKARA. A technique for making a more or less complete post-mortem examination through an incision in the upper abdomen. *Indian Jour. Med. Res.* 15(4): 907-908. 1928.

10349. MEURMAN, Y. Beobachtungen an diffuseiternden und nekrotisierenden Innenohrentzündungen mit besonderer Berücksichtigung der Pathologie der Schneckenwasserleitung und der Nervendurchtrittsstellen. *Acta Soc. Med. Fennicae "Duodecim"* [*Suomalaisen Lääkäriseuran Duodecim'in*] 13[Ser. B](1): 1-118. [Art. 2] 21 fig. 1930.—In 16 of 18 human cases of otitis interna studied, the ear not primarily affected was also histologically examined. The inner ear was infected (in rabbits) either directly or indirectly from the middle ear after chemical injury to the membranes of the fenestrae. A collection of slides from the inner ear of intrameningeally infected dogs were also examined. All these seem to show that a necrosis of the inner ear can result from different factors (hydrops, direct action of bacteria and toxins, and vascular injury). The human material seemed to show that meningitis of labyrinthine origin more often proceeds from a suppurating than from a

necrotized inner ear. Although a certain amount of necrosis develops after suppuration, meningeal inflammation more often takes place at a suppurative stage and does not require more penetrating necrosis. Animal experiments indicated that even with a severe necrosis the infection may be limited to the inner ear through the copious exudation of leucocytes, due to necrotizing bacterial action. In suppurating otitis interna, after fenestral infection, the nearest avenues of infection may be more exposed. In otitis interna due to arrosion of the labyrinthine capsula, those parts nearest the original spot of infection do not appear to become infected earlier. In diffusely necrotizing inflammation all the "performed avenues" are generally rather equally diseased. In most of the human cases the inflammation proceeded toward the meninges through the modiolus, secondly through the nerve canals of the vestibule, especially through those of the area maculae sacculi and lastly by way of the aquaeductus cochleae. In many cases many of the preformed avenues were simultaneously affected. In adults, owing to the anatomic structure of the canal, pathogenic germs rarely wander from the inner ear through the cochlear aqueduct to the meningeal spaces. In children the aquaeductus cochleae has a greater pathologic significance, as the narrow section of the canal is shorter. In occasional adult cases in which the lumen of the canal is open throughout, infection of the meninges may take place through the canal, as indicated also by some of the animal experiments. In the human cases examined the source of the inflammation from the meninges to the inner ear of the secondarily affected side is most frequently through the canal of the modiolus, then the aquaeductus cochleae, rarely by way of the canals of the vestibular areae foraminosae. Contrary to human pathology, the germs in rabbits and dogs are frequently conducted through the aquaeductus cochleae. —*From author's summary.*

10350. **MONTEIRO, HERNÂNI, e AMÂNDIO TAVARES. Sesamoideus e corpos estranhos articulares. [Sesamoid and extraneous articular bodies.]** *Arquivo Anat. e Antrop.* [*Lisboa*] 13(1/2): 157-172. 6 fig. 1929 1930.—The authors report several cases of intra-tendinous sesamoids, among which there is one of the left rhomboid. In 1 case the close connections of the foreign articular bodies with the capsular sheath were actual capsular incrustations. These concretions are osseous neoformations related to the sesamoids found in some muscles, and representing simple pathological productions of small posttraumatic osteomas in relation with a metaplasia of the interstitial connective tissue.—*H. Monteiro* (*transl. by P. L. Risley*).

10351. **[OMOROKOVA, L. I.] ОМОРОКОВА, Л. И. К патологической анатомии хронического энцефалита с резко выраженной липоидой дегенерации и появлением особых продуктов обмена (ателa) и включений. [Pathological anatomy of chronic encephalitis with lipoid degeneration, α bodies, and infiltrates.]** Известия Томского Государственного Университета (*Trans. Tomsk State Univ.*) 78: 143-181. 1926.—An excised fragment of the cerebral cortex in a case of Kozhevnikov epilepsy showed changes in ganglial cells and fibers, in glia, and vessels. Minute crystalline formations around the nuclei led the author to suppose that the nuclear region gives rise to α bodies. The patho-anatomical process was characterized by sharply degenerative changes of ganglial cells, destruction of neurofibrillae, break-up of the lipoids of protoplasm, liberation of decay products of fats and fatty acids. Sheaths and vessels were severely affected with endoarteritis, hyalin transformation and infiltrations, and lymphoid elements. The author concludes that the toxic elements came from the vascular system.

Precancerous changes in the rabbit's ear as brought about by the x-ray are described. Induction of cancer by this means in this animal was not easy, 2 or more years were required, and a relatively massive dosage, precaution being necessary, however, that no single dose was sufficient to produce tissue necrosis. Properly calibrated dosage alone was not sufficient, since in over 20 instances even with this, no cancer developed. Up to the point of actual tissue defect, there were no differences in the reaction type. But at this time there were evident differences in reaction in the case of the lesions which eventually became cancerous. In the non-cancerous ones, there eventually appeared a central perforation, which was preceded by the appearance of small but typical warty lesions. In some instances there was no evidence of preceding atrophy, while in others this was prominent; in the former type the warts continued to grow during the period of exposure but did not become cancerous. In still other cases there was early, extensive, but delimited necrosis. In those lesions which proved to be precancerous the course of events was atrophy, perforation, and apparent repair, but with the successive and continued appearance of small erosions, with final hyperplasia at these points and the usual, but not invariable, development here of cancer. In these cases the cancer did not form as a regular part of the peculiar inflammatory reaction, but only through a peculiar evolution of this. So that x-ray dermatitis in general is to be regarded as precancerous only in the practical sense; cancer in these circumstances appears as a secondary, non-essential change; and in a morphological sense the precancerous lesion would be restricted to the secondary erosive changes described here. III. In a general discussion and summary of the phenomena, the author takes the position that precancer does not represent so much a condition of an actual definite disease type, as an intermediate phase between a normal organ and one that is cancerous. This phase is characterized

morphologically by proliferative epithelial changes, with atypical arrangement of these and abnormally formed cells and nuclei, accompanied by reactive changes in the underlying connective tissue. Even these changes are not necessarily precancerous, since even here they are of distinctly reversible character. Just as important in the conception of precancer is the history, as concerns character of the irritant, the terrain irritated, in the widest sense,—race, localization, nature of tissue, heredity, possible metabolic or endocrine functions,—and the the details of action of the irritant.—*H. E. Eggers.*

10359. **SCOTT, H. H. Tuberculosis in man and lower animals.** *Privy Council Med. Res. Council [Gr. Britain] Spec. Rep. Ser.* 149. p. 1-270. 1930.—This study is based on 150 autopsies on animals from the Zoological Gardens of London and 300 post mortem findings in subjects dying from tuberculosis. A relative absence of this disease is due to relative isolation and consequent freedom from exposure to infection. This also holds true for wild animals. In cattle, tuberculosis may remain localized, or the serous membranes may demonstrate the typical "pearl"—or "grapes"—formation. The anatomical characters of tuberculous lesions in dogs are quite peculiar, often revealing whitish, circumscribed tumors in lungs, liver and kidneys, without the usual histological picture of giant cells, epithelioid or small lymphoid cells. The infection of all examined cats was the bovine type, no infection with human type could be found. While the lesions of liver, spleen, lymph glands and lungs in gallinaceous birds are due to the avian type, parrots and canaries are susceptible to both the avian and the mammalian types. The existence of tuberculosis in wild animals under natural conditions is highly improbable. Tuberculosis in captive wild animals takes a rapid course as those animals have little power of resistance, not having been previously in contact with infection. Monkeys, and especially the New World Cebidae, show almost no resistance to infection. As the respiratory tract acts as the commonest portal of entry and the lymphatic system provides the principal channel for the distribution of tuberculosis, the author studied the arrangement of plexuses and the lymphatic drainage by injecting every drainage system. While the theory of hereditary transmission of constitutional predisposition to tuberculosis is fading more and more, the occurrence of congenital infection via the placenta, the umbilical vein or during labor can not be denied. Almost 70% of the 300 autopsies performed show that mouth and nasal passages were the primary portals for infection; the number of infected children below the age of 10 years was 225. The presence of tuberculous mediastinal glands not only indicates a pulmonary focus but also the side where the focus should be found. Only 32 cases were definitely of alimentary origin and 24 died of meningeal tuberculosis. Of these cases with terminal meningitis 4.4% were children and 20% adults. Involvement of the urinary tract alone is as rare as the tubercular infection of the internal genitalia. The author stresses Cummins' classification of tuberculosis in "natural" and "modified" types. Natural tuberculosis, or the action of tubercle bacillus in man or animal not immunized against the toxin of the bacillus, is the character of tuberculosis in young people and children, while the modified type usually is a secondary infection or reinfection, characterized by fibroid changes around the lesions, and mainly local in its spread. Pulmonary hemorrhages occur only in the modified disease. In tuberculous septicemia, miliary tuberculosis is the predominating type, but the typho-bacillosis of Landouzy is not uncommon. The 3rd group, the transient tuberculous bacillemia, where the bacillus can be found in the blood, may yield some 20-25% positive cases. Wild birds in captivity show the alimentary tract as the common portal of entry for the bacillus. The subperitoneal tissue, the mucous membrane and the duodenum are first in the line of organs demonstrating infiltrations and ulcerations, the liver and spleen come second and the lungs third on the list. Reptiles and all the poikilothermic animals may show 3 types of tubercle bacilli: the ordinary saprophytes, the human type, and the piscine tubercle bacillus, highly pathogenic for reptiles, fish, frogs, adders, and slowworms. In regard to mycosis in mammals, the author found that when tuberculosis and mycosis are associated in man, it is usually an implantation of the latter on the former. Mycotic infection is not usually associated with emaciation and the wasting is rare, even when tuberculosis and actinomycosis exist simultaneously.—*P. J. Trudel.*

10360. **SEGA, A., e A. BRUSTOLON. Leucemia monocitica o reticulo-endoteliosi leucemica?** *Haematologica 1. Arch.* 10(6): 471-506. 2 pl. 22 fig. 1929.—The authors report the histopathologic findings in a case of acute leukemia characterized by a remarkable increase of leucocytes (38.193) of which nearly 50% were monocytic elements. That the latter were derived from the reticulo-endothelial system was indicated by the numerous transition stages and by the existence of a generalized hyperplasia of the reticulo-endothelial cells. Presence of a small proportion of immature red corpuscles (2%) gave evidence of a primary lesion in the erythropoietic system. The case is accordingly classified as an erythro-leukemia, type acute monocytoid leukemia. The paper has an extensive literature on the monocyte, on monocytoid leukemia, and on endotheliosis.—*N. A. Michels.*

Path. and Bact.* 34(6): 793-797. 2 pl. 1931.—In a chronic diabetic cat, depancreatised and not supplied with insulin, killed at 32 weeks after depancreatisation, intense deposits of hemosiderin were found in the liver parenchyma, and slighter deposits in spleen, lymphatic glands, and kidney. In addition, the testis showed complete aspermia.—*E. W. Reid.*

10362. **TSCHERNJAWSKI, JOHANN. Chromoblastomycosis.** *Arch. Dermatol. u. Syphil.* 157(1): 196-206. 6 fig. 1929.—The various phases of this essentially tropical disease are reviewed, followed by the author's case, originating in Leningrad. A source of the infection in nature is suggested since in this case infection followed injury by underbrush while riding horseback. The lesion was a small one on the leg, resembling tuberculosis. The histology is described in detail, the distinctive feature being the large size of the parasite as seen in sections. In culture the organism was brownish-black. The disease was reproduced in a rat upon subcutaneous inoculations but did not extend to the viscera. The mycologic examination was inadequate for accurate classification of the fungus. It may belong to the genus *Acrotheca.*—*F. D. Weidman.*

10365. **WARREN, SHIELDS, (foreword by ELLIOTT P. JOSLIN). The pathology of diabetes.** 212p. 2 col. pl., 83 fig. Lea & Febiger: Philadelphia, 1930. Price $3.75.—Insulin has thoroughly convinced us of the truth of the insular hypothesis as etiologic explanation of diabetes. It is striking that any lesion found in the diabetic pancreas can be duplicated in the nondiabetic, whether it be hyalinization, fibrosis, lymphocytic infiltration, or hypertrophy of islet tissue. Hydropic degeneration of islet cells, hemorrhage into them, and pyknosis of their nuclei

are probably post-mortem artefacts. 28% of the 259 diabetic pancreases studied showed no demonstrable lesion. Insulin causes glycogen deposition in those areas in which it is normally found but from which the diabetic process has caused its disappearance. The disturbance in fat metabolism leads particularly to the deposition of lipoids in the reticulo-endothelial cells, increased frequency of gall-stones, and atheromatous changes in the arterial intima. The latter is to be distinguished from medial calcification of the Mönckeberg type, thromboangiitis obliterans, and endarteritis of the terminal arteries which are not of diabetic origin. Acidosis renders the intimal ground substance permeable to lipoid-laden blood; lipoid droplets remain behind, gradually accumulating to form the atheromatous plaque. There is limited but definite evidence that islet tissue regenerates. In 23 persons having diabetes for more than 15 yrs. the only striking change was in the degree of arterial sclerosis. The observation of cases of hyperinsulinism gave the final proof to the insulin origin of diabetes. Only a very rare patient dies of an overdose of insulin. The autopsy methods of the Palmer Memorial Hospital are described.—*B. Y. Glassberg.*

10366. WARWICK, W. TURNER. Valvular defect in relation to varicosis. An investigation of the valvular mechanism of the venous return from the lower limbs. *Lancet* 219 (5598) : 1278-1286. 8 fig. 1930.—Varicose veins are of congenital origin. The factor responsible is either weakness of the vessel walls or valvular deficiency. Observations and experiments made in support of the former view are unfruitful. The author records experiments in support of the primary valvular defect and considers the venous system of the lower limb. Observations on the bodies of 30 young subjects below the varicose age are grouped into (1) The congenitally non-varicose type—normal; in 75% of young subjects the valving is perfect throughout all systems. (2) The congenitally varicose: (a) In the internal saphenous type, some of the main perforating veins have no valves, so that muscular contraction drives blood into the superficial veins as well as up the leg. (b) In the external saphenous (muscular) type, the main perforating veins join muscular trunks, some of which are congenitally unvalved. There may be also isolated valvular defect in a muscular branch not connected with perforating veins. (c) Of the deep type, the important femoral valve beneath Poupart's ligament may be absent; the valves of the main venae comites below the knee may be absent over a considerable length. (d) In the superficial type, no defect of valves in superficial veins apart from their perforating veins could be made out. With each type of inherited primary valvular defect, the secondary factors responsible for increase of abnormal refluxes into superficial veins produce the corresponding lesion by the end of the 2nd decade of life.—*W. T. Warwick.*

10367. WASSILJEFF, ALEXANDER A. Hodenveränderungen bei Lepra. *Zeitschr. Urol. Chir.* 30 (5/6) : 375-391. 1930.—The material from 8 cases of leprosy is separable into 2 main groups: (1) the chiefly interstitial type of leprous orchitis shows: In type A, infiltration of the lepra bacillus in the interstitial tissue of the testis, with development of inflammatory infiltrations composed of lymphocytes, plasma, and lepra cells, which at once affects spermatogenesis, so that formation of spermatozoa stops and marked degenerative changes occur in the tubular epithelium. In type B, intense proliferation of the interstitial leprous granulation tissue but with development of a sufficient number of collagen fibers; spermatogenesis ceases and the canals are filled with degenerated epithelial cells the protoplasm of which sometimes contains lepra bacilli. This type resembles the picture in common interstitial or syphilitic orchitis. In type C, besides the hyalinization with thickening of the membrana propria of the tubules and atrophy of the tubular epithelium, there occur canals with a somewhat similar epithelial lining, but with a more marked proliferation of the interstitial cells than is observed after the Steinach operation. These interstitial cells proliferate in the regions in which the canals are not completely atrophic. In type D, complete replacement of the testicular elements by leprous granulation tissue. (2) The chiefly degenerative type shows: In type A, primary degeneration of the epithelium of the seminiferous tubules on the basis of a general intoxication with much less inflammatory change in the interstitial connective tissue. In type B, complete destruction of the epithelium. The seminiferous tubules are replaced by hyaline masses which preserve only their contour. The interstitial tissue is likewise thickened and hyalinized.—*G. Milles.*

10368. WÄTJEN, J. Morphologie und Funktion des lymphatischen Gewebes. *Virchow's Arch. Path. Anat. u. Physiol.* 271 (2) : 556-571. 1929.—The interpretation of morphological findings in postmortem material must be carried out with reserve when it concerns lymphatic tissue. This is particularly true of the so-called "germinal centers." If nuclear or cellular destruction is observed here, it does not necessarily imply that in such localities there are physiological foci of lymphocyte destruction. Every marked indication of cellular dissolution in the germinal centers is the result of endogenous or exogenous toxins.—*J. Wätjen (transl. by O. F. Kampmeier).*

10369. WEIDMAN, FRED D., and JOHN H. BESANCON. Histologic differences in a "syringoma" of the face and shoulder. Employment of wax reconstruction. *Arch. Dermatol. and Syphil.* 21 (2) : 279-293. 11 fig. 1930.—Syringoma is the effect of hyperplastic embryonal vestiges in the skin. The authors' case was unique in that the face lesion could be referred to hair apparatus and that of the shoulder to the sweat glands. In the latter, certain cells were of the apocrine type seen in the axilla; other portions had undergone adenomatous hyperplasia. None of the apparatus communicated with the surface (wax reconstruction); due to the extreme complexity of its coils and branches, a single sweat unit could eventuate in a comparatively gross tumor.—*F. D. Weidman.*

10370. WEINER, W., und P. KAZNELSON. Über die zellige Zusammensetzung des Knochenmarkes nach Erfahrungen mittels der Sternalpunktion nach Seyfarth. *Folia Haematol. Arch.* 32 (3) : 233-261. 1926.—Only in blood disease are there significant alterations in the cellular composition of bone marrow. Myeloblastic marrow occurs exceptionally in myeloid leukemia, lymphoid marrow in a few cases of lymphatic leukemia, and erythroblastic marrow in severe anemia and polycythemia. The appearance of megalocytes and erythrogonia in greater numbers is characteristic of pernicious anemia. Both disappear at the remission. In symptomatic blood changes only insignificant changes occur in the cellular composition of marrow.—*Authors' summary (transl. by T. S. Eliot).*

10371. WERNER, CARL. Veränderungen der Zungenschleimhaut bei perniziöser Anämie. *Beitr. Anat., Physiol., Path. u. Ther. Ohres, Nase u. Halses* 23: 8-21. 1926.—Five cases are presented showing histological findings. In all inflammation of the tongue to a marked degree was present. One case of secondary anemia was of interest because the tongue gave the same picture as in the pernicious anemia patients.—*M. E. Winters.*

10372. WINGE, Ö. Zytologische Untersuchungen über die Natur maligner Tumoren. II. Teerkarzinome bei Mäusen. *Zeitschr. Wiss. Biol. Abt. B, Zeitschr. Zellforsch. u. Mikrosk.* 10 (4) : 683-735. 52 fig. 1930.—Taking as his point of departure an earlier work in which he had shown that in the crown gall of sugar beets the cells possess a tetraploid instead of the normal diploid number of chromosomes, the author made a chromosome count in the cells of tar carcinomata in mice. The number of chromosomes in the normal cells of the mouse is 40. A series of 86 chromosome counts on old and young tumors gave a curve with 2 peaks, the maximum of one peak being about 38, or a little under the diploid count, while the maximum of the other was about 68, or a little less than double this count. The young tumors

(papillomata) gave the small chromosome counts; the large chromosome counts occurred in the old, malignant tumors, the author regards malignant tumors as comprised of cells descended from cells which have received an abnormal number of chromosomes through local stimulus, increased demand for nutrition and intensity of growth and disturbed metabolism producing here and there a loss of certain chromosomes and finally a doubling of others. The duplication of chromosomes coincides with an increased tendency to growth and malignancy; it is no accident, the author maintains, that the young papillomata have a relatively small chromosome count, while the highly developed carcinomata have a large chromosome count.

10373. AIELLO, GIUSEPPE. Ricerche quantitative sui prodotti di scissione dell'albumina nel liquido cefalorachidiano. [Studies on protein derivatives in cerebrospinal fluid.] *Biochim. e Terapia Sperim.* 17(10): 414-418. 1930.—In tubercular meningitis the N content of cerebrospinal liquor was 0.41-2.4 (normal values, 0.40-0.60), but no relation existed between N content and severity of the meningeal affection.—*M. Comel.*

10374. ALOSI, B. I veleni emolitici e le alterazioni del fegato. [Hemolytic poisons and changes in the liver.] *Haematologica* 10(4): 379-404. 10 fig. 1929.—The following experiments were performed on dogs: 1) Sole ligation of the bile duct for a month. 2) Rapid death by acute hemolytic poisoning (55 cc. of 4% sol. of toluylendiamin, repeated injections, death—30 days, or 13 cc. of pyrodin, 4% sol. 2 injections, death—5 days; or 16 cc. of tellurium 2‰, death—1 day). 3) Production of chronic anemias by slight doses (2%) of one of the above poisons. 4) Poisoning followed by ligation of bile duct. 5) Ligation of bile duct with subsequent poisoning. The most common morphological changes effected were leucocytic infiltrations in the lobular centers, necrosis, fatty degeneration of hepatic cells, gorging of Kupffer cells with bile pigment, increase of connective tissue. Large doses of any of the 3 poisons caused an intense erythrocateretic (destroying) activity in all organs (Kupffer cells, spleen, bone marrow, lymph nodes). With small doses the hemolytic activity was intensified only in the Kupffer cells. Severest degree of icterus was developed by toluylendiamin, less potent were pyrodin and tellurium. With ligation of the bile duct changes in hepatic cells were less extensive than with toluylendiamin poisoning, icterus was likewise decidedly less developed. If ligation followed poisoning (e.g., with tol.) icterus was markedly increased with correspondingly pronounced changes in the hepatic cells. If ligation preceded poisoning, icterus was very intense, even after a single injection. The author contends that the degree of icterus is proportional to structural changes in the hepatic cells, that the coloring matter of the bile (fabricated in the Kupffer cells) passes into the bile capillaries by way of the hepatic cells, which amid other functions are the primary pathways of bile excretion. If the hepatic cells are destroyed through the toxic action of poisons or structurally altered through chemical action of the bile, the coloring substance passes into the blood stream directly or by way of the lymph stream.—*N. A. Michels.*

10375. ANTONIOLI, G. M. Ricerche sulla coagulazione del sangue in vitro e sul tempo di emorragia nei malati di tumori maligni. *Minerva Med.* 9(45): 735-738. 1929.—No characteristic differences were found either in blood coagulation time in vitro or in time of coagulation between patients with malignant tumors and normal persons.

10376. ASHE, BENJAMIN. The hemoglobin percentage and the red blood cell count in Bright's disease, myocardian insufficiency and hypertension. *Arch. Internal Med.* 44(4): 506-530. 1929.

10377. BEJARANO, JORGE. Le syndrome de l'hypotension artérielle à Bogota. *Rev. Méd. et Hyg. Trop.* 21(6): 178-180. 1929.—Bogota, situated on the Andes, is about 2,650 meters above sea level and has a temp. varying from about 12 to 20 [C], according to the season. Cases of hypotension are frequent there, particularly among women. Several types occur among young girls. The most frequent form of idiopathic hypotension is observed among girls from 13 to 16, and is accompanied by acrocyanosis and Martinet's hyposphyxia, and, in cases of long duration, by trophic alterations of the nails and even deformity of the fingers (thickening of the terminal phalanx). The aspect of infantilism is striking. Bejarano refers to work by Umaña on the basal metabolism of inhabitants of the plateaus of Bogota and Boyaca, tending to show a retardation of nutrition; and the work of Calderon of Bogota (1913) which calls attention to the frequency of pluriglandular insufficiency among the women of the region.

10378. BELLONI, JEAN-BAPTISTE. À propos des "tremblements d'action" et des "tremblements de repos." *Jour. Neurol. et Psychiatrie* 29(3): 137-145. 4 fig. 1929.—On the basis of personal investigation, the author dissents from the ideas proposed by De Jong, Kleist and Froment, who deny that the tremors of paralysis agitans are rest tremors. He finds from tracings of voluntary movements in dementia paralytica and paralysis agitans that tremors, in the former, accompany all the phases of a muscular contraction, while in the latter, the tremor appears during extension or during tetanic contraction. He has also observed that the tremor of paralysis agitans ceases with the application of the Esmarch bandage, above the proximal insertion of the muscle or muscles in question, while in dementia paralysis it persists. The cessation of the tremor in paralysis agitans in absolute repose is bound up with modification of the muscular tone and it is, therefore, not an action tremor. The pyramidal clonus is interpreted by the author as a phenomenon of spinal automatism, and the intention tremor of multiple sclerosis as a mixture of cerebellar ataxia and pyramidal clonus.—*J. Belloni (transl. by P. Hillkowitz).*

10379. BIER, ARTUR. Der Blutmilchsäurespiegel beim Morbus Basedow in der Ruhe und während der Arbeit. *Klin. Wochenschr.* 8(28): 1306-1309. 1929.—Persons with a hyperactive thyroid consume an excessive amount of O while resting, fatigue easily and consume an enormous amt. of O upon the slightest exertion. Recovery from exertion is very slow. The lactic acid concentration of the blood parallels the O consumption, i.e., it is above normal during rest, increases tremendously on the slightest exertion, and remains high long after the return to rest. The prolonged fatigue noted by these patients may well be due to the high lactic acid concentration in the blood.—*M. Hanke.*

10380. BRÜDA, BOTHO E., und VIKTOR KOSZLER. Über den Einfluss des Serums anämischer Tiere auf das Tumorwachstum. *Klin. Wochenschr.* 8(26): 1223-1224. 1929.—Tumor cells grow more rapidly in serum from anemic animals than in normal serum (cf. compare

article by Carnot, Itami and Tadenuma), and more rapidly in anemic than in normal rats.—*M. Hanke.*

10381. **BRUNI, GAETANO.** L'Ittero nel corso della polmonite. Ricerche sul ricambio emoglobinico nella polmonite. [Icterus in pneumonia: researches on the hemoglobin exchange in pneumonia.] *Clin. Med. Italiana* 60(3): 205-218. 1929.—Studies of hemoglobin metabolism were made in 18 pneumonia cases. The author believes that the results give renewed support to the theory that excessive destruction of red corpuscles is the primary cause of pneumonic icterus.

10382. **BURGESS, NORMAN.** Calcium metabolism in diseases of the skin. *Guy's Hosp. Rep.* 78(3): 350-361. 1928.—Urticaria, especially that associated with marked dermographism, prurigo of the Besnier type, total alopecia areata, light sensitization of the adult type, and eczema usually showed a content below normal of serum Ca precipitable by ammonium oxalate. In some cases of acroasphyxia and of erythema pernio there was decreased precipitable serum Ca; in other cases it was normal. Cases of urticaria, prurigo, eczema, and those cases of acroasphyxia and chilblains with a low serum Ca were improved by treatment with Ca and parathyroid. Only 1 case of psoriasis showed a decreased precipitable serum Ca. Two out of 5 cases of seborrheic dermatitis had a lowered serum Ca, these cases being accompanied by a marked secondary infection. In 1 case of erythema multiforme, serum Ca was slightly decreased. In a case of Darier's disease and of acrodermatitic continua serum Ca was normal. In most of the skin diseases studied total serum Ca was normal, even if the precipitable Ca was lowered. The author attributes the lowered serum Ca to an increased irritability of the sympathetic nervous system. The increased irritability is probably of endocrine origin.

10383. **CUTLER, ELLIOTT C.** Studies in the experimental production of abscess of the lung. *Jour. Coll. Surg. Australasia* 2(2): 201-216. 12 fig. 1929.—There is no agreement concerning the etiology of pulmonary abscess. The 2 divergent views as to the mechanism which leads to the production of abscess of the lung are: (1) aspiration and (2) embolism. Attempts were made to produce pulmonary suppuration by aspiration. In no case was a definite abscess produced. Then experiments utilizing an infected embolus were initiated. Artificial emboli were constructed of a small excised segment of vein tied off at both ends and filled with the desired bacteria. When sufficiently virulent organisms were introduced walled off abscesses resulted in about 90% of the attempts. Experiments were then set up in which the animal's immunity was built up by vaccination with the same organism later used in an infected clot; in these experiments the lesion varied with the resistance of the host. More recently experiments in chronicity have been carried out. After abscesses were well established by the use of vein segment emboli, coughing was produced by the use of an irritant gas. The abscesses increased in size and remained active up to 4 or 5 weeks. Next the rôle of mouth organisms was investigated. A large number of insufflation experiments and intrabronchial bronchoscopic placements were performed with material swarming with spirochaetes and freshly obtained from the gum margins of a patient with pyorrhea alveolaris. In none of these experiments were abscesses produced. In the next series of experiments scrapings from the gum margins of the patient with pyorrhea alveolaris were placed in a vein segment embolus and freed into the venous circulation. Abscesses were produced with almost universal regularity; they were comparable with those in the human being and one remained active for 101 days. In another series of experiments clots formed in test tubes were infected with the same material from gum margins and then freed into the venous circulation; again abscesses which became chronic were produced.—*E. C. Cutler.*

10384. **DAVIS, LOYAL, and LEWIS J. POLLOCK.** Experimental convulsions: a crucial experiment to determine the convulsive site. *Arch. Neurol. and Psychiatry* 20(4): 756-763. 2 fig. 1928.—The authors decerebrated animals by ligating the basilar and carotid arteries. They demonstrated that tonic convulsions can be produced in these animals by injecting picrotoxin. They conclude that the character or degree of the tonic convulsive seizure is dependent not on the level of the decerebration but on the presence in the particular animal of certain tonic reflex patterns prior to the administration of the convulsive drug. The complete pattern of a convulsion necessitates the background of normally distributed tone and motor function. The clonic element of experimentally produced toxic convulsion, although permitted to appear by the integrity of the central nervous system, is not due to any toxic stimulation of the cerebral cortex. Lastly, typical tonic and clonic convulsions can be produced in an animal in which the cerebral cortex is intact but in which the brain stem alone is stimulated by the picrotoxin.—*W. F. Jacobs.*

10385. **DIAS, ANNES.** Azotémie chloropénique. *Presse Méd.* 38(30): 500-502. 1930.—Chloropenic azotemia is not a disease but an important syndrome which may be due to various causes, such as severe diabetes, dehydrating diseases, overfeeding or inanition, hemorrhagic pancreatitis, duodenal occlusion, etc., which produce a protein disintegration in the system. The main features of the syndrome are deficiency of NaCl, fixation of Cl in the tissues, azotemia and azoturia, frequently accompanied by hyperglycemia, and often by rise of the alkaline reserve as the Cl of the blood falls. The disintegration of protein (favored by lack of salt), attracts toward the tissues the salt which protects them; the azotemia induced by the lack of salt is not a protective reaction to raise molecular concentration and osmotic pressure but the result of autophagy. The chloropenia may be either the result of a diet poor in NaCl or of the fixation of chlorides in the tissues. KCl and chlorides of other bases will not serve to replace NaCl in the treatment of acute chloropenic azotemia.—*From author's conclusions (transl.).*

10386. **EISELT, RUDOLF.** Problémy stárí. [Problems of age.] [With French, German, and English summaries.] *Bratislavské Lekárske Listy* 9(9): 644-674. 1929.—The work is divided into biology, clinical aspects and pathology of age. In the 1st part, is discussed the physical chemistry of colloidal matter, the theory of protoplasmic hysteresis (Růžička), and the opinions of Lumière. In the 2nd part, the changes brought about by disturbances of internal secretions are discussed. In advanced yrs. hypothyroidism predominates, yet a decided myxedema is relatively seldom observed. The insufficiency of the parathyroid seldom leads to pronounced tetany; as a rule, only an augmentation of the mechanical nervous irritability is observed. The influence of the parathyroid is often shown in the metabolism of Ca which often amounts to osteoporosis. The hypophyseal changes show themselves mostly in acromegaly which often occurs in older women. In senility, the hypofunction of the genital glands is of first importance, i.e., hypofunction of the interstitial gland in ♂ and of the corpus luteum in ♀. Whether the operations according to Steinach and Voronoff rejuvenate, stimulate, or really regenerate the function of the internal secretion of the genital glands, has not yet been indisputably proved. We do not yet know what influence this rejuvenation has on the length of a man's life, or whether, by elimination of some troubles, it only makes life more bearable. In the 3rd part, diseases to which old age is most subject and which influence the general constitution of individuals are discussed. To this category belong, first of all, atheroxerosis and atherosclerosis which cause 52% of the deaths. Disturbances of the vegetative nervous system and vasomotor cramps lead to dyspragia and Raynaud's disease; atheroma of the vessels leads to embolism and thrombosis, which in turn lead to senile gangrene. The weakness of the heart is the cause of gradual diminution of blood-pressure which gives rise to disturbances in the

nourishment of various organs, as of the central nervous system. Tuberculosis of the lungs often appears in old age and causes 20% of the deaths. Clinically it is characterised by a poverty of the physical symptoms, immuno-biologically by diminution of the allergy; only 48% of senile cases react to tuberculin. These immuno-biological changes may be connected with the dispersity of the colloids. Pulmonary tuberculosis in old age has often the same character as stage II according to Ranke. Tuberculosis of articulations and bones, and insufficiency of the liver are often observed in old age. Hypocholia is a symptom typical of senile insufficiency of the liver. —*From author's summary.*

10387. ELFVING, A. R. Über Blutdruck und Nierenfunktion der Prostatiker. *Acta Soc. Med. Fennicae "Duodecim"* 9(1-2): 1-299. 1928.—The author examined the blood pressure and the renal function of 102 cases of prostatic disease and arrived at the following conclusions: A single functional test (with the exception of the water- and the concentration test and then only when they show the renal function to be good) is not sufficient for appraising the renal function in prostatic disease, when the question at issue is to decide whether to operate. By aid of 3 tests, i.e., the indigo carmine test, the water- and concentration-test and the residual N method, it is possible to determine the indications for all operations in prostatic disease and to prevent sudden death from uremia. A detailed discussion is given of the significance of these tests.—*A. R. Elfving.*

10388. ENKE, GERTRUD. Kreislaufstudien bei Infektionskrankheiten. II. Mitteilung: Blutdruckmessungen bei akuten Infektionskrankheiten. *Zeitschr. Klin. Med.* 111(3/4): 349-356. 3 fig. 1929.—Typhus, erysipelas, diphtheria, tonsillitis, Vincent's angina, and scarlet fever are all featured by a fall of blood pressure, systolic and diastolic, under the usual individual level beginning during lysis and lasting into convalescence. The mechanism involved is unknown.—*W. T. Dawson.*

10389. FABOZZI, S. Sul ricambio della melanina nel melanosarcoma. *Riv. Med.* [*Napoli*] 7(1): 16-18. 1 pl. 1930.—In 3 series of experiments small fragments of melanosarcoma, living and killed, were grafted into the subcutaneous connective tissue of guinea-pigs. The grafts did not survive, but the living grafts induced the appearance of nodules of pigment-forming cells, the pigment being apparently melanin. The killed grafts and controls of normal pigment-forming tissue (guinea-pig or rabbit choroid), coloring matter (sepia) and artificial melanic substance produced no such response.

10390. GIAUME, CESARE, e ADA RANNO. Sulle alterazioni dell'ossificazione condrale nel rachitismo sperimentale dei ratti. [Alterations of cartilaginous ossification in experimental rickets in rats.] [With French summary.] *Riv. Clin. Pediatr.* 27(11): 829-837. 1929.—The author used a rickets producing diet on young rats. He studied bone formation in these rats, killing them at different stages, and examining bone sections. He found the usual irregular and retarded bone growth, and concludes that this irregular ossification is caused by a lack of timely stimulation for the cartilage cells. In other words, ultra-violet or vitamin D acts as an essential cartilage stimulant.

10391. GIORDANO, CESARE, e LUIGI GRIVA. Sull'influenza di alcuni aminoacidi (l-prolina ed l-ossiprolina) nella ricerca della bilina e del bilinogeno. [The influence of certain amino-acids (l-prolin and l-oxyprolin) on bilin and bilinogen elimination.] *Arch. Sci. Med.* 53(12): 784-790. 1929.—This study was undertaken to test the conclusions of Fischer and Meyer-Betz that the unstable pyrroles (which include the known derivatives of crystallized hemoglobin and of bilirubin) are transformed in the organism as well as in the test-tube into urobilin. In the first experiments 2 dogs were fed for a preliminary period of 5 days on a diet of rice and sugar (rice is almost entirely free from amino-acids with a pyrrole nucleus), for which gelatin (which contains 9.5% of l-proline and 14.1% of oxyproline) was then substituted, the feces and urine being analyzed for bilin and bilinogen; both fell slightly instead of rising. The bilin and bilinogen elimination in a patient with jaundice was also studied on ordinary diet and with gelatin; in the latter case there was little change in bilin and urobilin elimination. In later experiments the isolated amino-acids proline and oxyproline were used. One dog was fed rice, milk and sugar for 6 days; then a mixture of proline and oxyproline was added to the diet. No increase of urobilin or urobilinogen occurred in feces or urine. Another dog fasted 24 hrs.; then a solution of proline and oxyproline was injected intramuscularly; the urobilin and urobilinogen were determined immediately before and 45 min. after; showing an increase after injection. The authors conclude that substances with pyrrole nucleus, given by mouth, cannot be utilized by the organism for the synthesis of the urobilin molecule.

10392. GÖNCZY, VITÉZ ISTVÁN VON, JOSEF KISS, und ZOLTÁN ENYEDY. Über den Venendruck und dessen Tagesschwankungen. *Zeitschr. Ges. Exp. Med.* 70(1-2): 236-250. 1930.—Venous pressure, diastolic and systolic pressure, pulse amplitude and pulse frequency were measured simultaneously on 60 patients suffering from various diseases. Determinations of venous pressure were also made on 7 normal individuals. These showed a fluctuation of about 1 cm. sometimes in one direction and sometimes in the other. In 3 cases of neurasthenia and bronchial asthma the venous pressure fluctuated more than normal. In the neurasthenic the diurnal fluctuation was 3 cm. The increased fluctuation was probably due to vasomotor disturbances associated with the climacteric. Results of measurements in hypertonic diseases could be divided into 3 groups. In 6 cases of hypertonia with stasis the venous pressure was proportional to the severity of the stasis; the diurnal fluctuation was between 0.5 and 5.8 cm. In 2 cases of chronic nephritis complicated with a beginning of cardiac stasis or a functional disturbance of climacteric origin the venous pressure was increased (maximum was 20.5 cm.). Diurnal fluctuation was between 2.8 and 3.5 cm. In a case of nephrosclerosis with cardiac stasis the venous pressure was 12.4 cm. The diurnal fluctuation was 2.1 cm. In a case of pure climacteric hypertonia, increased venous pressure and a certain irregular diurnal fluctuation in pressure were observed. Although the arterial pressure fluctuated in paroxysms the venous pressure remained normal. The diurnal fluctuation in venous pressure was 3.5 cm. In heart and vascular diseases with mild cardial decompensation the venous pressure barely reached 12 cm.; in a case of marked decompensation it was 21 cm. but in both conditions the diurnal fluctuation was between .5 and 6.8 cm. Exercise increased diurnal fluctuation of venous blood pressure, in a case of chronic tonsillitis, neurasthenia, and degenerated myocardium. Venesection decreased the amount of blood, but increased the rate of circulation and in the heart and kidney conditions studied increased venous pressure. —*From author summary (transl.).*

10393. HANNON, R. R., E. SHORR, W. S. McCLELLAN, and E. F. DuBOIS. A case of osteitis fibrosa cystica (osteomalacia ?) with evidence of hyperactivity of the parathyroid bodies. Metabolic study I. *Jour. Clin. Investigation* 8(2): 215-227. 4 fig. 1930.—An officer of the merchant marine who had been 6 feet 1 inch tall and well proportioned, shortened to 5 ft. 6 in. in about 8 yrs. Coincident with the shortening he developed pigeon breast, protruding jaw, and excessive bone fragility. This man required 0.7 gm. of Ca to keep him in Ca balance instead of 0.4 gm., the usual amount. His blood P was very low, varying between 1.1 and 3.3 mgm. per 100 cc. Administration of parathyroid preparation increased his pain. The symptoms which this man presented resembled those in experimental animals given overdoses of parathyroid. Tumors of the parathyroid were found. This is one of the few metabolic studies performed on this type of disease.

10394. HAYNE, JAMES A. Endemic goiter and its relation to iodine content of food. *Amer. Jour. Public*

Health 19(10): 1111-1118. 1929.—A survey of 17,600 individuals in 20 counties in So. Carolina gives a goiter incidence of 3.8% compared to about 10 times that percentage in the goitrous states. An analysis of 15 So. Carolina vegetables gives high I contents as compared to analyses from other states by McClendon. The I content of So. Carolina potatoes averages 211 parts per billion, about twice the content of potatoes from Idaho, Maine, Michigan, Minnesota, and North Dakota. Iodine content of potatoes from the coast is less than from inland. Iodine analysis of various waters from So. Carolina is given. It is assumed that people eating fruits and vegetables from this state may reasonably expect not to have goiter.—*L. Seed.*

10395. HORSTERS, HANS. Studien über den Diabetes mellitus. II. Mitteilung. Über die Beeinflussung des Blutzuckers durch Gallensäuren. (Ein experimenteller Beitrag zur Frage der Bindung zwischen innerer und äusserer Sekretion der Bauchspeicheldrüse.) *Zeitschr. Ges. Exp. Med.* 66(1/2): 129-142. 1929.—The author concludes that the internal and the external secretion of the pancreas are closely connected. Staub came to the same conclusion through researches along a different line. By this explanation of the close connection of the inner and outer secretion the close relation between the carbohydrate intake and its utilization can be simply explained. Through study of the action of bile salts and their effect on the external pancreas secretion, the problem of hormonal connection of the inner and outer secretion of the pancreas can be approached and the metabolic disturbance in its theoretical as well as practical aspect clarified.—*H. Horsters (transl. by H. J. John).*

10396. HOUCK, G. J., and G. A. BENNETT. Polypoid fibroma of the left auricle (so-called cardiac myxoma) causing a ball-valve action. With report of a case. *Amer. Heart. Jour.* 5(6): 787-794. 6 fig. 1930.

10397. JEWTEJEWA, W. A., und W. W. OPPEL. Zur Charakteristik der alimentären glykämischen Kurve. III. Zur Frage der glykämischen Kurve bei Fieber (Abdominaltyphus). *Zeitschr. Ges. Exp. Med.* 64(1/2): 177-184. 4 fig. 1929.—During continual hyperthermia protracted and also somewhat higher curves with a long plateau are found. The increase of blood sugar begins only 15-30 min. after ingestion. Towards the end of the hyperthermia the curves—though still protracted—show no plateau. Defervescence beginning, low and short curves are found. Curves and fever show no constant parallelism. A disturbance of glycogenosis is supposed to exist at the height of the malady.—*Sz. Donhoffer.*

10398. KNAUER, HANS. Ist die Nephrose eine Nierenerkrankung? *Med. Klin.* 23: 862-866. 1927. Also in *Jahresber. Schlesisch. Ges. Väterländische Kultur* 1927 (2): 18-29. 1928.—The author presents the hypothesis that nephrosis is a metabolic disease with secondary changes in the kidney rather than a primary renal disturbance. There is in these individuals an elevation of the lipid content of the blood; an alteration of serum albumin tending to water retention in the tissues; a displacement of the K:Ca ratio with increase of K and decrease of Ca; the blood pressure is usually low and does not react normally on the injection of adrenaline. Similar disturbances are tied up with alterations in function of the thyroid gland, the adrenal and also during the toxemias of pregnancy. It is pointed out that the post-mortem findings in the kidneys of patients dying of acute nephrosis are strikingly mild. The kidney eventually suffers and the patient becomes uremic as the result of injury incident to the elimination of retained substances from the blood.—*W. W. Herrmann.*

10399. LEWIS, W. C. M. Some physico-chemical and biochemical aspects of malignant neoplasms. *Jour. Cancer Res.* 11(1): 16-53. 1927.—The various subjects touched upon are: electrical properties and permeability of cell contents and membranes; the rôle of Ca, of phosphatides, and of cholesterol in relation to reversible permeability; pH of tissue and blood in malignancy and its probable significance in connection with Pb ion concentration; protein content of tumor and neighboring tissue; antitryptic activity of blood in malignancy and the probable rôle of phosphatide or phosphatide-protein complexes; the digestibility and autolysis of tissues normal and malignant; the dual rôle of phosphatide and irreversible permeability produced by acid; prominence of glycolysis in malignant tissue and the chorion; possible rôle of phosphatides in glycolysis; the effect of Pb and certain other metallic ions of glycolysis; the phenomenon of infiltration and conclusion of Bierich regarding the special function of lactic acid; oxidation in malignant tissue; lipolytic and esterase activity in malignancy in relation to the excessive lecithin/cholesterol ratio. A brief account is given of the nature of the Pb suspension employed in the treatment of cancer. After the lapse of an hr. (or less), the material is converted in the serum mainly into phosphate. It is suggested that the ultimately effective agent is the Pb ion, Pb^{++}, which is presumed to act by retarding or bringing about cessation of one or more enzymic processes upon which the activity of the malignant cell depends.—*W. C. M. Lewis.*

10400. LOEWY, GEORGES. Expériences sur la production d'ulcères duodénaux par dérivation isolée de la bile. *Bull. et Mém. Soc. Nat. Chir. Paris* 56(7): 243-249. 4 fig. 1930.—Total drainage of bile was practiced on 7 dogs; in 3 cases the bile reestablished its course into the intestine. In the 4 experiments in which complete drainage continued to the end, the periods varied from 19 to 47 days. Necropsies showed gastro-intestinal inflammation in the earlier stages and duodenal ulcer, comparable to human ulcer, originating after the 36th day.

10401. McIVER, MONROE A., and JAMES L. GAMBLE. Body fluid changes due to intestinal obstruction. *Jour. Amer. Med. Assoc.* 91(21): 1589-1594. 1928.—Observations were limited to animals with simple blockage of the bowel lumen high in the intestinal tract and possible free drainage of secretions back into the stomach. Analysis of the digestive secretions and comparison with other body fluids, indicate that continued loss of digestive secretions causes rapid withdrawal of fixed base (chiefly Na) and of chloride from the body, with correspondingly extensive depletion of blood plasma and interstitial fluids. Depending upon the relative losses of Na and chloride ions, there also occurs alkalosis or acidosis. Progressive dehydration and distortion of acid-base structure is regarded as sufficient cause for symptoms and death in such cases with continued loss of secretions. The hypotheses of an absorbed toxin or the loss of some vitally important organic substance seem unnecessary. The type of obstruction discussed here is rarely present alone clinically, but forms only a part of the picture in most cases of intestinal obstruction. —*B. C. Russum.*

10402. MADSEN, JØRGEN. Variations in the hydrogen ion concentration and ammonia value of the urine in epileptics, with special reference to the "dysregulatio ammoniaci." *Acta Med. Scandinavica* 73(4): 337-398. 1930.—The material comprised 20 cases of epilepsy—cryptogenetic and organic—and 20 control individuals, all examined under uniform experimental conditions. The epileptics differed from the controls as follows: Frequent high values of pH or ammonia value or both, resulting in high regulation values. Almost constantly —but not specifically—greater variations in pH and ammonia value, that is: high scattering coefficients. Cryptogenetic epilepsy is almost constantly associated with greater variations of the regulation value, that is: higher μ (infraction of the Hasselbalch hyperbola regulation). Organic epilepsy is associated with great variations of the regulation value in but half the cases.—*Author's summary.*

10403. MAYR, JULIUS K. Zur Pathologie der Psoriasis vulgaris. *Arch. Dermatol. u. Syph.* 159(3): 598-604. 1930.—Normally there may be considerable variation in pH of the saliva during the day. In 1 normal individual

it varied from 6.7 to 7.1. In a patient with psoriasis it varied from 6.9 to 8.4, with most of the values lying on the alkaline side. In 25 cases of psoriasis vulgaris pH of saliva varied from 6.7 to 8. In 1 case of eczema impetiginosum, in which determinations were made every hour from 10 A. M. to 3 P. M., pH varied from 6.3 to 7.4. Most of the values were on the acid side. High pH generally occurred in the morning.

10404. **MELLANBY, EDWARD.** The relation of diet to health and disease. *Brit. Med. Jour.* 1(3614): 677-681. 1930.—After referring to the work of May Mellanby and C. L. Pattison in demonstrating the calcifying effect on the teeth of vitamin D and the anticalcifying effect of cereal, Mellanby goes on to describe his own results in working out the effects of diet on the central nervous system. Dogs showing severe incoordination of movement, often associated with weakness of the hind legs, and a scattered degeneration of the cord, were found as a rule to have been fed on much cereal, particularly the embryos of the grain; the degenerative changes occurred only in animals receiving a diet poor in fat-soluble vitamins. Since ergot of rye produces degenerative changes in the cord, ergot was used in the diet in an effort to clear up the problem. The degenerative nervous changes in experimental ergotism were found to depend on the absence of a protective diet factor—not vitamin D, which is present in ergot itself—but substances rich in vitamin A or a closely associated vitamin, such as egg-yolk, butter, codliver oil, mammalian liver oil and cabbage. This explains why nervous ergotism attacks the poor in times of famine; not only is the rye ergotized, but poverty prevents the use of protective foods such as milk, eggs and green vegetables. It also offers a probable explanation of the apparent capriciousness with which nervous ergotism attacks some members of a family and leaves others untouched; if a person has abundant stores of vitamin A in the liver and other organs, he will not be subject to attack by nervous ergotism until those reserves have been consumed. In studying the effect of grain embryo, it was found possible to produce the nervous degeneration of ergotism from the unergotized rye germ; that is, the nerve toxin present in ergot was present in small and apparently irregular amounts in the normal rye germ; the manifestation of nervous degeneration, however, seems to be in dogs dependent in part on individual susceptibility or resistance. This "toxamin," or toxin which may be antagonized by vitamin, is found in most cereals, most abundantly in the germ, yet present even in white flour, from which the embryo has been removed. The application is suggested of these facts to the study of other conditions characterized by combined subacute degeneration of the cord, such as lathyrism, pellagra and pernicious anemia. H. N. Green and Mellanby had previously reported experimental results on recovery induced by vitamin A from infections in rats. Mellanby here reports favorable results in the arrest of puerperal septicemia by the administration of vitamin A in a small group of clinical cases.

10405. **MERZ, WERNER.** Beitrag zur Frage der Entstehung der hypophysären Kachexie. (Ergebnisse zweier ungewöhnlicher Fälle.) *Frankfurter Zeitschr. Path.* 40(3): 452-476. 8 fig. 1930.—In both cases the anterior pituitary was not entirely destroyed; some remnants of functional tissue were found. Eosinophil cells were reduced in number and changed in appearance. The first case was chronic, the second acute. Etiology: In the first case, noxa associated with angina and colloid cyst; in the second, lymphatic sclerosis induced by cytotoxins (after Basedow) with pronounced symptoms of anterior pituitary deficiency.—*Author's summary (transl. by R. A. Muttkowski).*

10406. **MOULONGUET, P., et G. MIHAILESCO.** Recherches expérimentales sur la pathogénie des arthrites déformantes. *Presse Méd.* 38(27): 453-455. 6 fig. 1930. —Pulverized fresh or sterilized bone of various species was injected into the knee-joints of rabbits (number of experiments not stated). The animals were killed on the 5th, 10th and 20th days respectively and the articular tissues examined. By the 10th day all the bony debris in the articular cavity had been engulfed in the synovial membrane; some sequestra were being attacked by macrophages, and others were being reduced to masses of calcareous salts. Sections of tissues taken on the 20th day show a constructive activity at work alongside the destructive, resulting in the formation of free foreign bodies and the resuscitation of the particles of dead bone injected. The origin of the bone, whether heterogenous, homogenous or autogenous, seemed indifferent. The results are held to support Arbuthnot Lane's opinion that pressures and traumatisms are the principal, if not the only, cause of arthritis deformans.

10407. **MOURIQUAND, GEORGES.** Sur les états de précarence. *Presse Méd.* 38(10): 145-146. 1930.—All the avitaminoses may manifest an incomplete symptomatology, preceding the typical symptoms but not necessarily terminating therein. These latent avitaminoses may be due to dietary deficiencies alone, or to digestive troubles. A diet which would produce in guinea-pigs a chronic scorbutus comparable to the human disease (not produced by the Holst-Frölich diet) was sought, and found in a daily ration of barley, hay and sterilized lemon-juice. The latter was experimentally shown to check scurvy if used as the quantities of raw lemon-juice required for the same purpose. The barley-hay-sterilized-lemon-juice diet, then, is poor in vitamin C but not entirely devoid of it. On this diet typical scorbutic symptoms would generally appear toward the 80th day, but would, as a rule, tend toward spontaneous recovery, or at least remission—for relapses, with intervals of 30 to 300 days between, were frequent, though generally followed by recovery. If, from this vitamin-poor diet, the hay was withdrawn, the barley being increased to maintain the same number of calories, in most cases the scurvy appeared toward the 40th instead of the 80th day. It was as if the unstable balance maintained by the original diet were so disturbed by the withdrawal of the N, mineral salts, vitamin A, etc., contained in the hay, that the small doses of vitamin C contained in the lemon-juice could no longer ward off scurvy. As a rule, restoration of the hay to the diet caused disappearance of the scurvy symptoms. An explanation was sought through experiment of the clinically observed facts that the greater number of scorbutic children were of normal, and sometimes over normal, weight at the outset of the disease, and that typical, clearly defined scurvy was seldom observed in hypotrophics except in presence of an infection or other factor capable of turning the scale from latent to patent avitaminosis. A ration of 30 units of barley+15 units of hay+1 cc. sterilized lemon juice, given to guinea-pigs of the same weight and age, invariably produced scurvy toward the 15th or 20th day. If the diet were reduced to 10 barley+5 hay+1 cc. sterilized lemon juice, scurvy did not make its appearance; but if, toward the 20th day, the barley and hay ration were increased, typical scurvy would be produced in 3 or 4 days. The foregoing experiments, made during the winter, were resumed during the summer; and now the puzzling fact appeared that scurvy was produced in the animals on the 10+5+1 diet as well as in those on the 30+15+1 diet. Reduction of the summer ration to 5+5+1, however, sufficed to prevent scurvy. The explanation appears to be that the needs of the body for vitamin C increase with the body weight. A diet which increases the body weight, while offering no increased supply of vitamin C, turns the scale toward scurvy. The 10+5+1 diet had prevented scurvy during winter because it was insufficient to prevent a slow decline in weight. Fewer calories are necessary to maintain a constant level of body weight in summer than in winter, however; therefore the same diet maintained the weight stationary in summer and permitted a development of scurvy. This is offered as an entirely new observation in regard to scurvy; it is analogous to the classic fact that a liberal diet is necessary as a

foundation for experimental beriberi and rachitis. (Number of experiments not stated.) Clinically, the cases of outspoken scorbutus are few in proportion to the number of children on diets poor in vitamin C. Latent avitaminoses, however, are frequent, and frequently unrecognized. They are due, not to complete lack but to partial deficiency of vitamin C. A diet relatively poor in calories as well as in vitamin C may produce a condition of latent avitaminosis, which a more liberal diet (still lacking in vitamin C) will transform into scurvy.

10408. **MYGIND, S. H., and DIDA DEDERDING. Studies on some cutaneous and subcutaneous phenomena and their relation to the labyrinthal alterations in Mb. Menièri.** *Acta Oto-Laryngol.* 13(4): 474-488. 1929.—Menière's disease is not a morbus sui generis, according to the authors, but a characteristic, though changeable, complex of symptoms, by which the ear in predisposed individuals, like an extremely sensitive manometer, indicates any change in the general vasomotor and, especially, capillomotor state and in the water metabolism of the body. It is a matter of course that corresponding processes of water deposit also take place in other parts of the body. In nearly all the authors' Menière-patients different pathological phenomena in all parts of the body were observed, appearing and disappearing in sympathy with the ear troubles.—*From authors' summary.*

10409. **NAGEL, A. Untersuchungen über die Vitalfärbung in vitro gezüchteter Fibrozyten erwachsener Kaninchen. II. Die Beziehungen zwischen Fettablagerung und Deponierung von Neutralrot und Methylenblau. [Vital staining of fibrocytes of the adult rabbit grown in vitro.]** *Zeitschr. Wiss. Biol. Abt. B. Zeitschr. Zellforsch. u. Mikrosk. Anat.* 10(4): 744-755. 7 fig. 1930.—The process by which vital stains are deposited in the cell is shown as altogether comparable to that of fatty infiltration. Both fat and stain are deposited in preformed vacuoli; and in mitosis both are indifferently distributed to the daughter cells. Both processes are fully reversible. The fat in the cells of tissue in vitro is apparently formed, not from the living substance of the cells, but from the culture medium.—*From author's summary (transl.).*

10410. **NATHANSON, G. Des processus pathologiques occupant l'appareil olfactif chez les personnes ayant subi une intoxication aiguë, involontaire, par l'oxyde de carbone.** *Acta Oto-Laryngol.* 13(4): 409-418. 4 fig. 1929.—In the winter of 1928-1929 there were numerous accidents in Stockholm from illuminating gas and coal gas. In view of Gruber's experiments (which showed that the characteristic odor of illuminating gas is perceived with a concentration corresponding to 0.003% of CO and that toxic effect is felt in man only at concentrations of 0.02-0.05% CO), the author questioned why waking adults did not perceive the danger before the process became fatal. In 3 out of 4 necropsies on persons dying of gas poisoning, pathologic processes involving a weakened olfactory sense were demonstrable, and their presence in the other case was possible. Nathanson suggests that an epidemic of influenza may have contributed to the number of persons exposed by blunted sense of smell to the danger of gas poisoning.

10411. **REVOLTELLA, GIOVANNI. Ricerche sull' istamina nell'eclampsia puerperale. [Studies on histamin in puerperal eclampsy.]** *Boll. Soc. Ital. Biol. Sperim.* 5(3): 377-380. 1930.—During eclampsia or in the preeclamptic stage unusual amounts of histamine were found in the placenta, in the fetal blood and in blood of the mother, in the fetal organs and in urine of the the mother. In the normal pregnant woman no histamine, or very small amounts of it were found in blood.—*M. Comel.*

10412. **RICHON, et GEORGE. Le "paradiabète" de la pneumonie.** *Rev. Méd. Est.* 57(18): 601-604. 4 fig. 1929.—A comparison of the glycemic curves in diabetes before and after treatment on the one hand, and in the febrile and convalescent periods of pneumonia on the other.

10413. **SAGER, W. WARREN, and ALLEN C. NICKEL. Localization of bacteria in tissues of lowered resistance.** *Arch. Surgery* 19(2): 1086-1089. 1929.—In a study of postoperative wound infection, abscesses which were produced by subcutaneous injection of $AgNO_3$ into rabbits originally found free of blood infection remained sterile but became infected secondarily following the intravenous injection of bacteria.

10414. **STEFKO, W., und M. TSCHEROKOWA. Veränderungen und Struktur des endokrinen Systems bei Tuberkulose.** *Beitr. Klin. Tuberk.* 73(6): 791-798. 1930.—The aim of the study was to define the pathologic-anatomic changes in the individual organs; and also to discover the general structure or formula imposed on the endocrine constellation by the individual constitutional types of tuberculosis. The material studied included necropsies on 530 cases of tuberculosis; in 68 of these all the endocrine glands were removed to give an opportunity for an impression of the endocrine changes as a unit. The glandular changes described in detail are those of the hypophysis, the thyroid, the pancreas and the suprarenals. While apparently the endocrine glands are the most resistant of all organs to tuberculosis, this study shows that they undergo very essential changes, the peculiar character of the tuberculous process being especially marked in the thyroid. Apart from this, the general endocrine structure in the thoracalasthenic group of patients (in which among adults, pulmonary tuberculosis prevails) shows the predominating influence of the thyroid and of the anterior lobe or Pars intermedia of the hypophysis, with marked insufficiency of the suprarenals and of the insular apparatus of the pancreas.

10415. **TEPLOFF, J., und A. KOSCHEWNIKOWA. Über den Gehalt an Elektrolyten im Blutserum bei Herz- und Gefässkrankheiten.** *Klin. Wochenschr.* 8(26): 1222-1223. 1929.—The Ca and K content of the blood serum is not changed in cases in which there is no circulatory insufficiency. The Ca, Cl and P are below normal in patients with cardiac decompensation. The K/Ca ratio is usually elevated in patients with cardiac insufficiency, particularly in patients with a cardiosclerosis.—*M. Hanke.*

10416. **TOULOUSE, E., L. MARCHAND, et A. COURTOIS. L'encéphalite psychosique aiguë azotémique.** *Presse Méd.* 38(30): 497-500. 3 fig. 1930.—A condition affecting chiefly women, mostly young, fatal in 14 out of 15 cases, is described. Clinically, it comprises a prodromal period, sometimes 4 wks. long, sometimes lacking; an active period of 5-8 days, with fever, agitation and mental confusion; a 3-5 day lull; and a terminal period with 2-4 days of progressive torpor and a few hours of coma preceding death. The urea content of the blood and cerebrospinal fluid rises markedly. Histologically, the nervous system lesions were those of an acute encephalitis, with evidence of toxic infection, satellitosis and perivascular lymphocytic reactions localized especially in the subcortical regions of the frontal lobes and the medulla oblongata. In 9 cases the liver, kidneys and spleen were histologically examined and found greatly congested, with fatty degeneration of the liver in many cases (sometimes necrosis). The cause has not been discovered; an infectious toxin seems probable, but the authors insist upon the differences between this condition and epidemic encephalitis. They suggest that more than 1 infectious agent may be concerned in their cases.

10417. **TRASK, JAMES D., CHARLES O'DONOVAN, Jr., DOROTHEA M. MOORE, and AGNES R. BEEBE. Studies on pneumonia in children. I. Mortality, blood cultures, and humoral antibodies in pneumococcus pneumonia.** *Jour. Clin. Investigation* 8(4): 623-653. 3 fig. 1930.—This study was made on 163 pneumonia cases, 73 in children and 90 in adults. The conclusions are: (1) Fixed type pneumococci cause a large proportion of the cases of lobar pneumonia in childhood, and are uncommon in cases of broncho-pneumonia during this period. (2) Pneumonia due to Types I and III pneumococci has a much lower mortality in children than in adults. (3) Heavy blood stream invasion in chil-

dren with pneumococcus pneumonia is rare. (4) Protective bodies appear in children with pneumococcus pneumonia, as in adults, about the time of recovery. Type specific agglutinins similarly appear in children, but their appearance is less frequent than in adults, and apparently less frequent in younger than in older children. (5) The marked pneumococcemia seen in fatal cases of lobar pneumonia in adult man suggests a special reactivity on his part towards the pneumococcus different from that of the child.—*Authors' conclusions.*

10418. VILLA, LUIGI. Alterazioni del ricambio colesterinico nella epatiti ipermegaliche infettive e considerazioni sui fattori di regolazione di detto ricambio. [Factors regulating changes in cholesterin metabolism in hypertrophic infective hepatitis.] *Boll. Soc. Med.-Chir. Pavia* 42(3): 439-453. 1928; also in *Pensiero Med.* 1928(14): (3-15). 1928.—The author deals first with the results of 3 cases of hypertrophic chronic infective hepatitis in 2 of which, luetic in nature, were found signs of altered cholesterol metabolism, (increase in blood, diminution in bile, xanthelasma), second, with ex- and endogenous cholesterol, and third, with various manifestations of changes in the liver, kidneys, etc. A concept is formulated that these diverse manifestations may be considered together as disturbances of a single metabolic syndrome contributed to by various organs with functions not yet entirely known.—*L. Villa (transl. by J. G. Edwards).*

10419. WEECH, A. A. Association of keratomalacia with other deficiency diseases. *Amer. Jour. Dis. Children* 39(6): 1153-1166. 2 fig. 1930.—Attention is called to the type of diet eaten by the average Chinese, to the high incidence in China of deficiency diseases in general and to the possibility of several deficiency diseases coexisting in the same patient. A study of 13 children with keratomalacia is presented, in which particular pains were taken to establish the presence or absence of other deficiency diseases. In some instances keratomalacia was associated with rickets, while in others it was not; previously active rickets may be healing when keratomalacia becomes active. Reasons are given for the belief that the lack of association of rickets and keratomalacia in some patients is due to exposure to sunlight rather than to dietary factors. No definite association of keratomalacia with beriberi was observed. However, the history of 1 infant is presented who exhibited moderate cardiac hypertrophy in association with rickets and keratomalacia. The size of the heart decreased following the addition of yeast to the diet. No definite association of keratomalacia with scurvy was observed, although 2 patients presented purpura of obscure etiology. The relation of edema to deficiency diseases in general is discussed. Five of the 13 patients with keratomalacia showed edema, believed to be in most instances a manifestation of some dietary fault distinct from that which caused the keratomalacia. Anemia was present in some of the patients and marked undernutrition in the entire group. The inference is drawn that their diets were not only qualitatively but also quantitatively insufficient.—*Author's summary.*

10420. WILLIAMS, J. LISLE. The uric acid increase in the blood of patients with cardiac decompensation. *Jour. Lab. and Clin. Med.* 15(1): 13-17. 1929.—Williams states that no systematic study (except his own) of blood uric acid in patients with heart disease but without nephritis is to be found recorded. He here reports a study of 22 patients with cardiac decompensation but without nephritis, 14 ♂ and 8 ♀, aged from 8 to 70 yrs. The results indicate that this condition is associated with a marked increase in concentration of blood uric acid and a moderate increase in urea and non-protein N. Improvement in cardiac efficiency was followed by marked decrease in uric acid and moderate decrease in urea and non-protein N of the blood, with a diminution in the size of the liver and decrease in edema. The results tend to support the view that the liver is an important organ in uric acid metabolism.

10421. WILLS, LUCY, and MANECK M. MEHTA. Production of pernicious anaemia (Bartonella anaemia) in rats by deficient feeding. *Brit. Med. Jour.* 1(3625): 1167-1168. 1 fig. 1930.—The dietetic survey of various classes of women in Bombay suggested that the disease occurring in pregnant women known as "pernicious anemia of pregnancy" was closely connected with a relative deficiency of vitamins A and C in their diet. In this connection a series of experiments was carried out at Coonoor in which diets relatively deficient in these vitamins led to the production of a severe anemia in intact albino rats, especially in the ♀ animals; it was further shown to be a true "Bartonella anemia." The term "Bartonella anemia" is used to describe the well-known anemia of rats which occurs after splenectomy in infected stock, and is associated with the appearance of Bartonella "organisms" in the red cells; it is used without prejudice as to the exact nature of these small bodies. A severe anemia, more severe and more frequent in ♀♀ than in ♂♂, has been produced in rats by feeding them on diets low in vitamins A and C. Blood examination revealed the presence of *Bartonella muris* in the red cells of the anemic rats. Splenectomy experiments showed that all the Coonoor rats were infected with Bartonella. Liver, spleen, and vitamin A concentrate failed to protect the rats from this anemia after splenectomy.—*Authors' summary.*

10422. ZALLOCCO, A. Il riflesso oculo-cardiaco nella infezione tbc. dell'infanzia. [The oculo-cardiac reflex in the tuberculosis of childhood.] *Minerva Med.* 9(43): 655-659.—The oculo-cardiac reflex was found normal in 24 out of 50 children affected with tuberculous tracheobronchial adenopathy, abolished in 4 cases and inverted in 22. The frequency of the inversion is attributed by the author to the degree of intoxication, which sensitizes the sympathetic and makes its action prevail over that of the vagus.

ANIMAL PATHOLOGY

INFECTIOUS AND OTHER DISEASES OF LOWER ANIMALS

F. S. JONES, *Editor*

R. W. GLASER, *Associate Editor*

(See also in this issue the subsection "Lower Animals" in the sections Immunology and Filterable Viruses; and Entries 9071, 9539, 10336, 10349, 10359, 10604, 10608, 10654, 10668, 10670, 10674, 10675, 10680, 10693, 10694, 10700, 10701, 10708, 10714, 10715, 10720, 10728, 10729, 10743, 10747, 10752, 10766, 10781, 10789, 10790, 10791, 10814, 10840, 10862, 10876, 10935, 10937, 10987, 11083, 11502)

10423. AELLIG. Ikterus gravis beim Hunde. *Zeitschr. Infektionskr. u. Hyg. Haustiere* 39(3): 169-210. 1931.—The author studied an outbreak in Bern, with 90% of fatalities; 38 animals were observed. The clinical symptoms are lack of appetite, somnolence and icterus, with slight increase in temp. The dogs are emaciated and strongly icteric. Various writers have reported that the cause is a Leptospira similar to those of the rat and of Weil's disease. It is difficult to demonstrate but may be found in the kidney by the Levaditi method, without pyridin. The author produced symptoms similar to those in dogs by injection of material from kidneys of sick dogs. In some cases he demonstrated a spirochaete in the blood and organ extracts of guinea pigs by dark field examination. These animals exhibited the characteristic icteric and hemorrhagic condition, especially of the

lungs. The mode of infection in dogs is unknown. Considerable space is given to a discussion of the relation of this disease to disease in man. While guinea pigs are easily susceptible to Weil's disease, adult dogs are quite resistant, although young dogs are reported to be somewhat susceptible. It is reported that convalescent serum is of some value in protecting susceptible animals; various trials at chemotherapy failed.—*L. D. Bushnell.*

10424. ARNBERGER, ANTON. Über das Vorkommen von Paratyphus-Enteritis-Bakterien bei Darmerkrankungen der Pferde. *Tierärztl. Rundschau* 37(39): 689-692. 1931.—From 53 cases of horses with alimentary diseases of varying severity, it is concluded that, at least in Vienna, paratyphoid bacteria are comparatively rare in alimentary diseases of horses and only in the severest cases can they be found. This is supported by the investigations of Savic.—*From author's summary (transl.).*

10425. ARNDT, H. J. Kommt Kropf bei wildlebenden Tieren vor? *Berliner Tierärztl. Wochenschr.* 47(41): 669-670. 4 fig. 1931.—While cases of goiter in domestic animals are not uncommon, cases among wild animals are very rare if not unknown. There is considerable difference between the thyroids of domestic animals and their wild relatives.

10426. BAARS, G. Über Gärtnerbakterien und -infektionen bei Rind und Ratte. *Miessner-Festschrift* p. 1-33. Fritz Eberlein: Hannover, 1930.—*Bacterium enteritidis* Gärtner does not represent a single entity but can be divided into several types biochemically, and probably also serologically and epidemiologically. First a division into 2 types seems logical. One comprises those in cattle; the other those frequently found in man after food poisoning and which are included in the so-called "rat poisons." In 476 fecal examinations and 360 blood tests, 3 healthy cattle were found excreting Gärtner bacteria in the feces. The agglutination titer of the blood of these cattle was 2,000-10,000; the author regards a titer over 500 as suspicious. In one cow, Gärtner bacteria were excreted in feces for 10 mo. Bacteria were also found in the milk, which was contaminated from the feces. No bacteria were found in urine, vaginal secretion, or liver. Four 1-wk.-old calves and a young bull were fed contaminated milk; 2 of the calves died. The bull and 1 calf did not become ill even after 1 mo. of such feeding. In their blood specific agglutinin was not demonstrated. The bacteria were not killed by spontaneous heating of manure piles. In 247 dead rats (wild), no Gärtner bacteria were found in heart blood, liver, or intestines. Feeding rats with various trade preparations of Gärtner bacteria (Ratin and Antiratol) gave no pronounced infections of wild rats.—*Author's summary (transl.).*

10427. BANG, OLUF, and H. CHR. BENDIXEN. The number of abortion bacteria in milk from cows that have calved. *Internat. Dairy Congr. Eng. Ed.* 1931 (Sect. 2): 124-125. 1931.—A summary.

10428. BERGE, RUDOLF. Die Pulloruminfektion der Hühner. *Miessner-Festschrift* p. 35-53. 1 fig. Fritz Eberlein: Hannover, 1930.—This disease is seen in both young and mature fowls. Focal changes in the lungs of chickens up to 3 weeks old, that have succumbed, are typical signs. Hens may acquire the acute septicaemic as well as the chronic form of the disease. Roosters are also susceptible. *B. pullorum* is regarded as identical with the agent of Klein's fowl typhoid. 15.4% of the brooding eggs from + agglutinating hens were infected, but *B. pullorum* tests on fresh eggs were always −. Sound hens were not infected when kept with infected ones (♂ absent). Exchanging the ♂ from sick to normal hens also gave negative results. The test tube agglutination method was a good method for determining pullorum infected hens (+ titer 1:100). A blood test given 4 times during the first yr. to about 400 pullets gave at the 3rd test no more + agglutinating birds.—*Author's summary (transl.).*

10429. BILLINGTON, S. G., E. LEAMINGTON SPA, W. TRIGGER, and H. S. CALDWELL. A preliminary note on a six years' investigation of canine distemper. *Vet. Med.* 25(5): 180-185. 3 fig. 1930.—Canine distemper is described as one of the "specific fevers." The blood yielded an organism called the distemper leptothrix, with a complex life cycle in which *Bacillus bronchisepticus* and a filterable virus are stages. The large leptothrix form grown on agar had therapeutic efficiency; other forms did not. In naturally immune animals an antigenic element was found associated with the globulin and then, when split off, the globulin was as effective a therapeutic agent as the leptothrix. Therapeutic inoculations were made with various bacteriological preparations representing stages in the life history of the streptococcus, such as coccoid bodies from red cells, the leptothrix, coccoid bodies from the leptothrix and *B. bronchisepticus*. Therapeutic treatments were also carried out with compound globulin-serum fractions and disintegration compounds. These preparations have shown marked curative results but are of slight prophylactic value.—*R. G. Green.*

10430. BOHL, B. K., und J. J. JAKOWLEW. Die pathologische Anatomie der Katzenleber bei Opistorchis felineus. *Virchow's Arch. Path. Anat. u. Physiol.* 279 (3): 724-730. 6 fig. 1931.—Of 12 livers of cats infested with *O. felineus*, some showed glandular epithelial proliferation; in others the infestation was accompanied by increase in bile ducts. The 2 conditions may not appear alone and one may seemingly be transformed into the other. Glandular proliferation is sometimes papillomatous and sometimes adenomatous in character, but these are frequently mixed. In the canals with the glandular proliferation, intense development of the smooth musculature is observed. The cystic type of spreading bile ducts sometimes dominates the pictures. At times the lesions are those of obturative (biliary) cirrhosis. This is faint except near the border of the liver, where it may be well developed. Overgrowth of the epithelium of the bile ducts may be taken as evidence of their regeneration. Glandular proliferation of the epithelium of the bile ducts, development of the bundles of smooth muscle and extensive growth of immature connective tissue are to be conceived as tissue development approaching the growth of tumors.—*Authors' summary (transl. by I. E. Newson).*

10431. BRUNETT, E. L. Transmission of Bacterium pullorum infection among mature chickens. *Rept. New York State Vet. Coll. Cornell Univ.* 1928/1929: 98-110. 1930.—17 mature, non-reacting hens were kept in a pen with 20 reacting hens for 7 mo. Testing the blood serum by agglutination with *Bact. pullorum* antigen, failed to reveal evidence of transmission. Non-reactors remained so during the entire period, and reactors maintained their titers throughout. Addition of 3 non-reacting mature male birds resulted in a number of the non-reactors becoming reactors. ½ of the surviving original non-reactors were found to harbor *Bact. pullorum* in the ovaries. Male birds did not react to the agglutination test or show evidence of infection on autopsy. A pen composed of 3 mature, reacting, male birds and 26 non-reacting, mature hens failed to demonstrate transmission. The high titer of the blood serum in the males indicated an infection. This was not proved, although the pericardial lesions suggested a localization about the heart. This is a common site for *Bact. pullorum* infection in males. If this tissue alone harbored infection, the experiment demonstrates the inability of such birds to transmit it to others.—*Author's summary.*

10432. BURGGRAAF, H. Paratuberculose op de oostkust van Sumatra. [Paratuberculosis on the east coast of Sumatra.] [With German and English summaries.] *Ned.-Indische Blad. Diergeneesk.* 43(4): 359-362. 1931.—This disease of cattle often runs a more acute course than in Europe, viz., 1-4 weeks. 6 suspected animals were tested, with dubious results, by subcutaneous injection of 10 cc. of 20% avian tuberculin solution.—*Author's summary.*

10433. CARLSTROM, BIRGER. Ueber die Ätiologie und Pathogenese der Kreuzlähme des Pferdes. *Skand.*

Arch. Physiol. 62: 1-69. 5 fig. 1931.—Since the blood may contain abnormal metabolites which are either causes or results of the muscle changes found in azoturia, it was necessary to make as many biochemical determinations as possible on this fluid. Bloods of lean and well nourished horses, both before and after exercise, were compared with each other in regard to corpuscle volume, sugar, amino-acids, creatin, total N, Ca, pH, dry weight and sedimentation. No characteristic differences were found. In azoturia there was an increased red cell volume which prolonged the sedimentation time. Blood sugar generally rose. Amino-acids remained quantitatively normal. Late in the disease total N increased. Creatin was somewhat increased. Total Ca was unchanged, while dry weight tended to be larger. With the exception of the increase in creatin and total N, the blood in azoturia resembled that from an animal after exertion. Lowering of pH was noteworthy. In normal horses lactic acid content of blood was 9-10 mgm. %; this was increased but slightly by exercise. In azoturia lactic acid content rose in proportion to severity of disease (16.1-182 mgm. %). Intravenous injections of lactic acid into horses, however, did not produce symptoms resembling azoturia. On the assumption that the increased lactic acid in the blood of azoturia cases might come from changes in the muscle, the muscle content in lactic acid and glycogen was investigated. The lactic acid content of affected muscles was found to be above normal. The glycogen content on the whole was increased, although it was relatively less in the affected muscles. If the glycogen accumulation in muscle is related to the muscle injury, it is most likely because of the increased lactic acid formation and subsequent CO_2 production. This might be brought about by O deficiency.—*W. J. Meek.*

10434. DAVID, HANS. Ein Beitrag zum Vorkommen von Paratyphus B-Schottmüller-Bakterien beim Rind. [Paratyphoid B bacteria in cattle.] *Deutsche Tierärztl. Wochenschr.* 39(39): 613-614. 1931.

10435. DAVID, HANS. Über Versuche mit dem Bact. psittacosis Nocard bei Wellensittichen. *Wiener Tierärztl. Monatsschr.* 18(2): 34-45. 1931.—Bacteriological and serological studies of 2 strains of *Bact. psittacosis* Nocard from the Kràl Museum (Vienna) demonstrated that this organism is identical with *Bact. enteritidis* Breslau and *Bact. aertrycke.* Feeding these organisms to 3 parrots produced a fatal disease in one of the orally-infected birds and in 4 placed with it, clinically and pathologically resembling true psittacosis. The parenteral injection of filtered extracts of internal organs of parrots dying as the result of an aertrycke infection produced no disease in 4 experimental parrots; hence it appears that the disease caused in parrots by the Nocard bacillus differs fundamentally from the more severe psittacosis in man, from which no bacteria have been isolated. According to the author's observations, the fatal intestinal diseases of parrots can be divided into 3 groups: (1) bacteriologically negative, non-infectious enteritides, frequent in old birds in captivity; (2) bacteriologically negative, infectious enteritides, producing psittacosis by means of a filterable virus and transmissible to man; (3) bacteriologically positive enteritides, usually caused by Breslau bacilli (aertrycke), for which transmission to man has not been positively demonstrated.—*H. David (transl. by W. W. Herrmann).*

10436. DURIN, GEORGES, et GEORGES UNGLAS. L'hématurie essentielle des Bovidés. Essais de traitement. *Rev. Path. Comp. et Hyg. Gén.* 31(421): 1025-1029. 1931.

10437. [DVIZHKOV, P. P.] ДВИЖКОВ, П. П. К патологической анатомии экспериментальной туляремии. **[Morbid anatomy of experimental tularemia.]** Вестник Микробиологии, Эпидемиологии и Паразитологии (*Rev. Microbiol., Épidémiol. et Parasitol.*) 9 (2): 169-185; German summary, 281. 9 fig. 1930.—Patho-anatomical studies of 40 water rats with spontaneous tularemia, and 18 guinea pigs infected with pure culture of *Bact. tularense,* were conducted. The guinea pigs were infected by rubbing into the skin emulsions of the spleen of infected water rats. Natural and artificial infection led to an acute septicemia characterized by acute vascular derangements, such as hyperemia and hemorrhages at the point of infection and in all internal organs, especially in the spleen and lymphatic glands. Development of bundles and larger foci of granular tissues mainly in the spleen and lymphatic glands was noted. Such lesions resemble tubercles but differ from them in polymorphism of cells. Under the influence of multiplication of *Bact. tularense,* the tissues undergo necrobiotic and later necrotic changes. Formation of granular lesions is more pronounced in guinea pigs than in water rats.—*G. A. Lebedeff.*

10438. EDGAR, GRAHAME. Studies in infectious ophthalmia of sheep. *New South Wales Dept. Agric. Vet. Res. Rept.* 6(1/2): 22-35. 1 pl. 1931.—The author reproduced this disease by instillation of a drop of lachrymal secretion from an affected into the eye of a healthy sheep. Other species tested were not susceptible. It was also readily transmitted when affected and healthy sheep grazed together on long grass, but not on short pasture. The disease was infective at all stages after earliest appearance of symptoms. Lachrymal secretion kept at 40° F. was non-infective after 48 hrs.; drying on paper destroyed its infectivity. A strong local immunity developed in recovered sheep. Treatment of affected eyes with 2.5% $ZnSO_4$ proved efficacious. None of the various bacteria isolated caused any abnormality when inoculated. Filtration tests failed to reveal a virus, but a virus etiology was not fully disproved. The immunological observations favored the theory that a virus is involved.

10439. EMMEL, M. W. Ueber bakteriologische und pathologische Befunde bei 500 Fällen von Kükenruhr. *Arch. Geflügelk.* 5(9): 278-284. 1931.—Except in acute forms of pullorum disease in baby chicks, the author believes that the lesions are sufficient for diagnosis. Essentially they consist of gray and brown foci, petechiae, and hemorrhagic areas in the liver; gray foci, pneumonia, and congestion are the lesions found in the lungs; firm, nodular, gray foci may appear in the musculature of the heart. Combinations of any of the lesions of the liver or lungs may occur. Lesions of the liver, heart and lungs were associated in 32.4% of the chicks, and liver and lung lesions in 39.6%; liver lesions alone occurred in 15% of the chicks. The causal organism was isolated from the livers of 84.2% and from the hearts of 74% of the 500 chicks studied.—*Author's conclusions.*

10440. FOWLER, ALEXANDER B., and NORMAN C. WRIGHT. Reactors in tuberculin-tested (licensed) herds. *Hannah Dairy Res. Inst. Bull.* 2. 1-51. 1931.—From 1923 to 1929, 28,221 official tests of herds in Scotland were recorded and 428 reactors found, representing an annual loss of 3 reactors per 100 of milking stock. Loss during the 1st yr. amounted to 5 reactors per 100, falling to 1 per 100 by the 5th and 6th yrs. It is shown that not more than 3 in every 10,000 animals in such herds can be considered as actively dangerous, i.e., 1 each yr. in the whole of the licensed tuberculin-tested herds in Scotland. The proportion of reactors infected from individual sources was as follows: Infected bought-in stock, 34.0%; infection through contact with other reactors or untested stock, 24.5%; infection from contaminated premises and pastures, 11.5%; miscellaneous and multiple sources of infection, 19.25%; anomalous tuberculin tests, 4.5%; source of infection not traced, 6.25%. Less than 10% of the reactors contracted infection from sources outside the control of the owner.

10441. FRIEDE, K. A., und N. N. SHUKOW-WERESCHNIKOW. Über den Einfluss der Aussentemperatur auf den Verlauf des Infektionsprozesses bei Kaltblütern. *Zeitschr. Immunitätsforsch.* 63(1/2): 93-106. 1929.—Frogs held at 20° C. succumb more quickly to infection with *B. septicemia ranarum* than at 10°. More rapid multiplication of organisms at 20° is not the cause of the more rapid death, since injection of a killed culture has the same effect. The normal protective mechanism does not seem to be impaired by a temp. of 20°.

so that this can not account for the phenomenon. The authors explain the results by the action of the higher temp. on the colloids of the cell, which are in a more labile state and can be more readily disturbed by the presence of another harmful colloid, such as the bacterial toxin, than would be the case at lower temp.—*C. M. Downs.*

10442. **GARCIA, ONOFRE. Carbohydrate and serological determinations of the bipolar gas-forming and non-gas-forming organisms isolated from lymph glands of slaughtered cattle.** *Philippine Jour. Sci.* 43(4): 565-575. 1930.—Both gas-forming and non-gas-forming bipolar organisms, morphologically alike, were isolated from lymphatic adenitis of slaughtered cattle. The gas-forming organism fermented glucose, galactose, levulose, maltose, sorbitol, dulcitol, inulin, and mannose. The other fermented glucose, galactose, levulose, maltose, sucrose, sorbitol, mannitol, inulin, and mannose. Therefore, the organism was identified as *B. bovisepticus.* Neither type grew on eosin-methylene-blue-lactose agar; each gave definite and distinct biochemical and serological reactions of its own; both were pathogenic for rabbits and guinea pigs. Some immunological phenomena, like the early appearance of immunity before antibodies are demonstrable, commonly noted by some workers with hemorrhagic septicemia organisms, were likewise observed in animals injected with the gas-forming bacteria.—*Author's summary.*

10443. **GASTHUYS, P. La destruction des rongeurs.** [Destruction of rodents.] *Bull. Agric. Congo Belge* 21 (4): 1048-1057. 1930.—Directions for use of poisons and bacterial infections for this purpose.

10444. **GEOFFROY, M. P. La tuberculose du bétail à Madagascar.** *Rec. Méd. Vét. Exot. École d'Alfort* 3 (Avril/Juin): 76-83. 1930.—The author reviews the history of the attempts to control tuberculosis in native cattle and hogs of the island, in considerable detail.—*G. L. A. Ruehle.*

10445. **GIERKE, ALFRED GUSTAV. Bacterial flora of the bovine pregnant uterus.** *Rept. New York State Vet. Coll. Cornell Univ.* 1928/1929: 61-74. 1930.—Of the 12 gravid uteri cultured, bacterial growth from the uterine mucosa was obtained in 5. In some instances the growth no doubt represented contamination, as in most cases when bacteria were found, 4 of the 5 inoculations remained sterile. Cultures from other parts of the genital tract above the internal os, together with those of the fetus and fetal fluids, were uniformly sterile. In 1 case *Staphylococcus albus* was isolated from the unsealed cervical canal. No microscopic evidence was found to support the theory that some of the fetal cotyledons are occasionally detached at some time during pregnancy, leaving the remainder to successfully function until normal termination. As a chorion is seldom found without a necrotic tip, its presence has not been described as abnormal. Cultures from these were always sterile. The evidence suggests that pathogenic and pyogenic bacteria are not harbored in the pregnant uterus under physiological conditions; and that they are not present for an appreciable time without detrimental effect on mother or fetus. Probably the majority of infections are carried to the pregnant uterus by the blood stream, and may localize in the uterine walls or fallopian tubes for an indefinite period before appearing on the surface of the endometrium.—*From author's summary & conclusions.*

10446. **GILMAN, HERBERT L. Further studies on the relation of the milk agglutination titre to the elimination of Bact. abortus from the udder of the cow.** *Cornell Vet.* 21(3): 243-251. 1931.—Milk from all 4 quarters of 113 cows was examined for agglutinin content and inoculated into guinea pigs. 108 of the 113 had a blood titer of positive at 1:80 or higher; 5 showed a lower titer. *Bact. abortus* was recovered from the milk of 62.9% of cows with a positive (1:80) blood titer, and of 78% of those with a positive (1:80) milk titer in 1 or more quarters. It was recovered but 5 times from milk showing a titer of less than positive at 1:80. The organism was recovered from 165 quarters—36.9% of all the quarters examined or 66.9% of those with a complete reaction at 1:80 or higher. Probably quarters showing agglutinins at 1:80 or higher are actively infected with the organism and may eliminate it at any time. Quarters showing agglutinins under 1:80 contain or eliminate the organism only in rare instances. However, if this be true, 85% of the animals in this series were udder-infected, inasmuch as 87 of the 108 positive cows showed agglutinins at 1:80 or higher in 1 or more quarters. Milk to be used for agglutination work must be from individual quarters. There seems to be considerable correlation between agglutination titer of milk and presence in it of *Bact. abortus.*—*Author's summary.*

10447. **GOETTSCH, M., and A. M. PAPPENHEIMER. Nutritional muscular dystrophy in the guinea pig and rabbit.** *Jour. Exp. Med.* 54: 145-165. 2 pl., 8 fig. 1931.—A generalized and apparently primary degeneration of the entire voluntary muscular tissue was induced in guinea pigs and rabbits when given a diet of rolled oats, wheat bran, skim milk powder, casein, lard, cod liver oil, NaCl and $CaCO_3$, with daily supplements of orange juice. Rats did not seem to be susceptible. The first diet employed had been treated with ethereal $FeCl_3$ to destroy vitamin E, but was complete in other known requirements. Later addition of vitamin E failed to prevent onset of the disorder, nor was treatment with $FeCl_3$ responsible. The lesions were not due to inanition, infection or scurvy; apparently some still unknown nutritional factor is concerned. The diet led to a progressive, highly selective and ultimately fatal dystrophy of the voluntary muscles, without other pathological lesions. The small intermuscular nerves and motor end plates remained intact. Guinea pigs developed lesions after 2-3 mo. on the diet, although 1 survived for 218 days. In very young rabbits, the disorder was apparent after 2-3 wks.—*M. Goettsch.*

10448. **GRAAF, C. de. Het bacteriologisch onderzoek van Z. G. Vleknieren van Vette Kalveren.** [With German, English and French summaries.] *Tijdschr. Diergeneesk.* 58(20): 1081-1097. 2 fig. 1931.—Bacteriological examination of 24 cases of nephritis maculosa alba in fat calves yielded *B. coli* in 7 instances. The calves examined were free from umbilical affections and arthritis. On the average, nephritis maculosa alba was found in 2% of the fat calves slaughtered. Most cases were encountered from Feb. to Aug.—*Author's summary.*

10449. **GRÄUB, E. Über die Bekämpfung der Tuberkulose unter den Rindern.** *Schweizer Arch. Tierheilk.* 73(7/8): 331-363. 1931.—The control measures employed in various countries for tuberculosis in cattle are critically reviewed, and recommendations are made for the special problems of Switzerland.

10450. **GREGORIO, SEGNI. Ricerche del virus brucellare nel siero di sangue degli ovini da macello della Toscana. (Contributo allo studio sulla distribuzione del virus brucellare fuori dell'organismo umano.) [Brucella infections in the blood of slaughtered sheep in Tuscany. A study of the distribution of Brucella outside the human organism.]** *Lo Sperimentale* 83(2/3): lvi-lvii. 1931.—The author carried out a serological investigation with melitensis and abortus antigens, separately and combined, on sera from 450 sheep. 15 were definitely positive, 21 doubtfully positive, and 9 suspicious.—*Maud L. Menten.*

10451. **[HALLER, O.] ГАЛЛЕР, О. Экспериментальная чума кошек. [Experimental plague in cats.]** Вестник Микробиологии, Эпидемиологии и Паразитологии (*Rev. Microbiol., Épidémiol. et Parasitol.*) 9 (2): 139-154; German summary, 277-280. 1930.—3 cats infected with plague virus by subcutaneous injection and by feeding, became ill but recovered. In other experiments, cats injected intraperitoneally and subcutaneously with more virulent cultures succumbed or developed plague and recovered. Other experiments indicated that adult cats are more resistant than the young. Infection of cats by feeding with infected milk

and meat in most cases gave negative results, except when bones were mixed with the food. Infection also occurred by means of contact with diseased cats, through discharges and lice. The author concludes that cats should be killed during plague epizooties in rodents.—*G. A. Lebedeff.*

10452. **HARE, TOM.** The pathology of follicular cysts of canaries: Hypopteronosis cystica. *Veterinary Record* 11(40): 1009-1011. 2 pl. 1931.—The clinical appearances, pathology and pathogenesis of the disease of canaries known to fanciers as "lumps" are described. The lesion is a cyst, single or multilocular, of a feather follicle, which arises during one of the moults. It is suggested that the disease be termed "Hypopteronosis cystica," its pathology being similar to Hypotrichosis cystica of swine. The disease appears to be an inherited defect of epithelium.—*Author's conclusions.*

10453. **HILL, CHARLES L.** Bang's disease control. *Internat. Dairy Congr. Eng. Ed.* 1931 (Sect. 2): 102-109. 1931.—The campaign to eradicate contagious abortion from Wisconsin is conducted largely through local veterinarians by blood testing, separation of positive from negative cattle, and, by sanitation and care, breeding herds free of the disease. Many large herds have been entirely freed of the disease.

10454. **HINDMARSH, W. L.** Infectious pneumonia of sheep. *New South Wales Dept. Agric. Vet. Res. Rept.* 6(1/2): 11-21. 1931.—Mortality occurred in 2 flocks of sheep on widely separated properties. Symptoms indicated that animals dying were affected with pneumonia. Post-mortems showed pneumonia and pleurisy. From pneumonic portions of the lungs an organism similar morphologically and culturally to Friedländer's bacillus was isolated. The disease was reproduced in guinea pigs, rabbits and sheep by intrathoracic and intravenous injection of cultures, and the bacillus was recovered.—*From author's summary.*

10455. **HUBER, F. L., en F. C. KRANEVELD.** Over de diagnose van miltvuur in Ned.-Indië, mede in verband met de wijze van opzenden van het ziektemateriaal. [Anthrax demonstration in the Dutch East Indies and the effect on it of the method of sending material.] [With German and English summaries.] *Ned.-Indische Blad. Diergeneesk.* 43(4): 333-348. 1 pl. 1931.—Although results were not uniform, probably due to faulty collecting of material in the field (too rapid drying of medium; collecting of blood too long after death), it seems that when properly handled, blotting paper and cotton-wool are as good a medium as chalk. A description is given of alterations of the anthrax-bacillus in carcasses under tropical conditions.—*From authors' summary.*

10456. **JUNGHERR, ERWIN.** Lechuguilla fever of sheep and goats; a form of swellhead in West Texas. *Cornell. Vet.* 21(3): 227-242. 1931.—The principal etiological theories of swellhead are photosensitization, infection and toxemia. Experiments proved that the prevailing form of swellhead in the Trans-Pecos country of west Texas is a plant toxemia called lechuguilla fever. By feeding *Agave lechuguilla* to sheep and goats, lechuguilla fever can be reproduced in its principal, clinical, and pathological manifestations.

10457. **KARRAS, WALTHER.** Künstliche Euterinfektionen (Streptokokken und Pyogenesbakterien). Gleichzeitig ein Beitrag zur forensischen Beurteilung der ersten Entzündungserscheinungen. *Tierärztl. Rundschau* 37(37): 653-655; (38): 676-679; (39): 692-696. 12 fig. 1931.—The inflammation begins by a hardening at the base of the teat, which occurs in ½-3½ hrs. after infection. The udder then enlarges and hardens, becoming painful. The amount of swelling then decreases and is determined only by measurements. This condition, known as inflamed udder and characterised by inflammation, swelling, and higher temp., was observed in 1-4 hrs. Macroscopic changes in the milk are not directly related to the seriousness of the tissue symptoms of the udder, but are determined by the kind of infective organism. The long chains found in chronic inflammation represent an adaptational form of streptococci occurring in animals.—*Author's summary (transl.).*

10458. **KÖBE, K.** Pyogenes-Infektion des Herzbeutels beim Schwein. *Miessner-Festschrift* p. 87-93. 5 fig. Fritz Eberlein: Hannover, 1930.—*B. pyogenes* may cause an inflammation of the pericardium, which has the characters of pericarditis serofibrinoso.—*Author's conclusions (transl.).*

10459. **KRUPSKI, ANTON.** Weitere Untersuchungen über die Pferde-Anämien. *Schweizer Arch. Tierheilk.* 73 (9): 435-442. 1931.—Colts, when treated intravenously, subcutaneously, etc., with culture filtrates of hemolytic streptococci, developed glanders-like symptoms but failed to develop anemia. Subcutaneous injection of living hemolytic streptococci was often attended by anemia and leucocytosis. The author comments on the variable results of his attempts to produce a solid immunity.

10460. **LÉGER, L.** Obstruction stomacale chez la truite par une formation mycétogène d'origine alimentaire. *Ann. Univ. Grenoble, Sci.-Med.* 6(1): 79-85. 2 pl., 6 fig. 1929.—In trout previously infected with the fungus, *Ichthyophonus intestinalis*, certain indigestible foods such as pieces of tanned skins, of which they are fond, give rise to bodies (by mycelial development of the fungus) which dilate and then almost completely obstruct the stomach. [See also following entry.]—*L. Léger (transl. by R. H. M'Gonigle).*

10461. **LÉGER, L.** Sur la nature et l'évolution des "sphérules" décrites chez les Ichthyophones Phycomycètes parasites de la truite. *Ann. Univ. Grenoble, Sci.-Med.* 6(1): 133-137. 1 pl. 1929.—The "spherules" described from the trout [see also preceding abstract], produced by the parasitic fungus of the *Ichthyophonus* type, were successfully cultivated on fish bouillon. Conjugation and the formation of oospores were obtained, which permit the placing of this fungus in the group, Entomophthoraceae.—*L. Léger (transl. by R. H. M'Gonigle).*

10462. **LENTZ, W.** Die Bekämpfung der Streptokokken-Mastitis im Lichte neuer Forschungsergebnisse. *Miessner-Festschrift* p. 113-117. Fritz Eberlein: Hannover, 1930.—Fundamental causes of Streptococcus mastitis are mistakes in care and feeding of milch cows; the streptococci are secondary. Daily doses of 50 gm. of calcidigal are helpful.—*Author's summary (transl.).*

10463. **LERCHE.** Können sich erwachsene Hühner mit Kükenruhr infizieren? *Tierärztl. Rundschau* 37(29): 511-513. 1931.—8 pullets hatched from eggs of positive reactor hens were placed with 4 pullets from healthy hens. In the following year, two 1½-yr.-old hens were added to this flock. In the course of the following month the majority of the pullets showed a positive serological reaction and laid infected eggs. Both adult hens were also infected. It is therefore possible for pullorum infection to be transmitted between mature hens. Fowls thus known to be carriers of infection should be either slaughtered or maintained in isolation.—*Lerche (transl. by H. Bunyea).*

10464. **MERCIER, L.** Aegagropiles de la souris blanche. *Bull. Soc. Linn. Normandie* 3: 24-25. 1930 (1931).—Felty concretions are described in the stomach of white rats dissected to observe the carcinogenetic effect of intraperitoneally injected tar.

10465. **MICHAILOW, B. N.** Pathologisch-histologische Veränderungen im Ganglion n. vagi, im Ganglion cervicale supr. sympathici, im Ganglion intervertebrale der Lendengegend und im Ganglion solare bei der Tollwut der Hunde. *Zeitschr. Infektionskr. u. Hyg. Haustiere* 39(4): 272-306. 1931.—The author briefly reviews the literature of the histo-pathological changes in the various ganglia in rabies of dogs and rabbits. A study of fixed and stained material revealed that cell increases noted in the lesions resulted from a proliferation of the connective tissue cells (fibrocytes, fibroblasts, etc.), the reticulo-endothelial cells (reticulocytes, endothelial cells, etc.) and other cells (epithelial, muscle, nerve). The changes are described as progressive-exudative and regressive-exudative in form; the former is most com-

mon. In early stages there appeared a mild inflammatory reaction of the tissues, the blood vessels were congested and there was swelling of the tissues and proliferation of the cells of the blood vessel walls. Around the vessels there is an accumulation of lymphoid cells, other cells with intensively stained nuclei, and cells of an epithelioidal character. There is also an increase in neutrophilic leucocytes. This proliferation is followed by a change in the ganglion cells, as indicated by disintegration of nuclei and protoplasm, and loss of staining reaction. These cells are wholly or partly replaced by proliferating cells which have migrated to this area. The changes may even involve the capsules of the nerve fibers. Similar changes were observed in other ganglia. It is concluded that the specificity of the changes is not sufficient for diagnostic purposes except when considered with clinical symptoms. The lesion of the exudative-progressive form is due to proliferation of the capsule cells of the reticular connective tissue of the vessel and to accumulation of neutrophilic leucocytes. The regressive exudative form is due to proliferation of epithelioidal and lymph cells. Both types of proliferation lead to destruction of ganglion cells.—*L. D. Bushnell.*

10466. **MITCHELL, CHAS. A. Bovine infectious abortion or Bang's disease of cattle.** *Canada Dept. Agric. Bull.* 150. 1-15. 2 pl. (1 col.). 1931.—A handbook on the disease.

10467. **MÜLLER, JOH., und J. BECK. Schwanz- und Sphinkterenlähmung (Neuritis caudae equinae) bei Kühen.** *Deutsche Tierärztl. Wochenschr.* 39(39): 609-613. 3 fig. 1931.—3 cases are described of tail and sphincter paralysis in cows, known previously only in horses. These were in cows 3½ yrs. old in the 4-6 mo. of pregnancy. Injections of 20 cc. of a 1‰ solution of strychnine between the 1st and 2nd tail vertebrae had no apparent effect.—*From authors' summary (transl.).*

10468. **MURIE, OLAUS J. An epizootic disease of elk.** *Jour. Mammalogy* 11(2): 214-222. 2 pl. 1930.—In the elk herd at Jackson Hole, Wyoming, there is a considerable loss each winter from necrotic stomatitis, due to *Bacillus necrophorus* which commonly obtains entrance to the tissues by injuries to the mucous membrane of the mouth made by the awns of squirrel-tail grass (*Hordeum*). It is estimated that in 1928 the winter loss was 5.8% of the herd. Loss was heaviest in the calves, 18.4% dying.—*L. R. Dice.*

10469. **NEGRO, G. À propos du microbisme latent.** [Latent microbism.] *Soc. Internaz. Microbiol. Boll. Sez. Ital.* 3(7/8): 467. 1931.—Microbism in guinea pigs was found to depend on environment and food.

10470. **OSTERTAG, R. von. Veterinary milk inspection, especially the treatment of milk infected with tuberculosis, epidemic abortion, streptococcus-mastitis, and with bacteria of the paratyphoid-enteritis group.** *Internat. Dairy Congr. Eng. Ed.* 1931 (Sect. 2): 98-101. 1931.—A summary.

10471. **OXSPRING, G. E. Bovine nasal granuloma.** *Jour. Roy. Army Vet. Corps* 2(4): 179-182. 1931.—This disease causes lesions in the nasal mucous membrane, especially in the septum nasi. Later, yellowish-red granular masses appear, accompanied by purulent discharges. The causal organism seems to belong to the streptothrix group and is very similar to *S. actinomyces*. Both horses and cattle are affected (mature animals only), but not water buffaloes. The period of incubation seems to be at least a yr. and after the appearance of the nodules, 2 mo. are required for them to become mature granulations. Tartar emetic injected intravenously seems to be a specific.

10472. **PAPPENHEIMER, A. M., and M. GOETTSCH. A cerebellar disorder in chicks, apparently of nutritional origin.** *Jour. Exp. Med.* 53: 11-26. 3 pl., 9 fig. 1931.—Upon simplified foods diets, consisting of casein, cornstarch, lard, skim milk powder, salts, paper pulp, yeast and cod liver oil, white leghorn chicks developed a disorder, accompanied by characteristic symptoms and by uniform and well-defined lesions of the cerebellum. Symptoms pointing to a derangement of function in the central nervous system appeared suddenly after the chicks had been 3-4 weeks on the diet, and were followed usually by death, although there were cases of recovery, followed by normal development. Symptoms included ataxia, tremors, head retraction, clonic spasms of the legs and stupor. Definite lesions, consisting of edema, necrosis and hemorrhages, were found in the cerebellum, occasionally in the cerebrum. The disease could not be transmitted to chicks maintained on the stock natural foods diet, by subdural inoculation. That it is a true nutritional deficiency disease is suggested.—*M. Goettsch.*

10473. **PALLASKE, G. Studien zum Ablauf, zur Pathogenese und pathologischen Anatomie der Tuberkulose des Schweines.** *Zeitschr. Infektionskr. u. Hyg. Haustiere* 39(3): 211-260. 10 fig. 1931.—In primary infection with tubercle bacilli the author considers 2 types of lesions of the lymph nodes in swine: (1) chiefly exudative; (2) chiefly productive. The 1st appears macroscopically as a more or less radiating caseation, due to the irregular structure of the lymph nodes. These areas exhibit centers of swollen cells surrounded by bands of coagulated fluids, fragments of leucocytes and hyperemic capillaries. Little fibrin is present and the oxydase reaction is especially marked at the periphery, where accumulation of epithelioid and giant cells is to be seen. The 2nd type is more diffuse and appears earlier. The lesions vary in size and the affected lymph nodes may become greatly enlarged. Histologically, the lesions vary from a diffuse regressive change to one of cell hyperplasia. Variations in these types may be great or the 2 may intergrade. In the productive form in the lymph glands of the neck, lymphoid tissue may be almost entirely replaced by tuberculous tissue. In such glands may be seen islands of isolated lymphoid tissue and irregular groups of epithelioid cells with fibrin between. In swine, one of the characteristics of the regressive stage of the tubercle is the excessive collection of leucocytes. This is due to the strong chemotactic nature of the degeneration products of the lesion, often causing the contents of the lymph gland to assume the appearance of pus. This lesion is commonly surrounded by a zone of epithelioid and giant cells, within a fibrous capsule arising chiefly from granulation tissue from the capillaries. Calcification and organization of the lesion appear early and regularly. Tissue destruction in the lymph nodes of swine is not so marked as, and the calcification of granulation tissue is greater than, in human tuberculosis. Generalization of tuberculosis in swine is common. The process is extended by formation of new tubercles at the periphery of the primary tubercle by growth. In these lesions secondary caseation appears. After formation of the secondary lesions, the organisms in the primary lesion appear to lose their toxicity and to act as foreign bodies. An immunity reaction (positive allergy) results from this lesion. Spread of the organisms to other tissues is through entrance to lymph channels or transfer by leucocytes to the blood stream. A generalization by way of the thoracic duct has not been demonstrated, although the disease is spread to all parts of the body. The miliary form in swine is similar to that in man. However, the primary type of lesion is not the same; in swine it is most commonly in the lymph nodes of the neck and not in the lungs. Generalization of bovine infection in swine appears to be a protracted condition with metastasis to few organs at a time and an extension from these points to adjacent tissues. A description of the histological changes due to bovine and avian tubercle bacilli in different organs of swine, is included.—*L. D. Bushnell.*

10474. **PIACCO, R. La dermatomicosi Saprolegniacea. Caratteri botanici delle Saprolegniacee dei pesci.** [Dermatomycoses of fish due to Saprolegniaceae.] *Giornale Risicolt.* 20(2): 26-29. 2 fig. 1930.—The botanical characters of *Aclya* and *Saprolegnia* are reviewed and the lesions produced on fish are described. Fish should be kept in clean water, frequently changed. In case of

attack, $NaClO_3$ and $KMnO_4$ (1 gm. in 100 liters) are recommended.

10475. POENARU, I. Recherches sur le rachitisme expérimental chez les poissons. Maladie par carence. [Experimental rickets in fishes.] *Arch. Vet.* [*Bucharest*] 21(5/6): 159-163. 2 fig. 1930.

10476. POENARU, I. Un procédé rapide d'isolement du Trichophyton chez les animaux. *Arch. Vet.* [*Bucuresti*] 22(3/6): 96-98. 2 fig. 1930.—According to the author's method, to different glucose or maltose media are added 10-15 drops of 30% KOH per tube; infected scales and hairs are held in KOH solution for 4-5 hrs. and some of this mixture is spread on the media and held at room temp. In 10-12 days a pure culture has developed.

10477. SCHECHTEL, EDWARD. Puchlina wodna u leszcza (Abramis brama L.). [Ascites in bream (A. brama).] [With German summary.] *Roczniki Nauk i Leśnych* (*Polish Agric. & Forest. Ann.*) 18(1): 81-84. 2 fig. 1927.—The body cavity of a bream contained about 750 cc. of fluid. The condition was due to a lesion in the lower wall of the swim-bladder. Through this lesion had penetrated an imperfect fungus (Dematiaceae) which had covered with black hyphae considerable portions of the swim-bladder wall.—*Author's summary* (*transl.*).

10478. SCHOOP, G. Das Vorkommen pathogener anaerober Bazillen beim Pferd ohne Vorliegen eines Gasödems. *Miessner-Festschrift* p. 187-195. Fritz Eberlein: Hannover, 1930.—In horse cadavers, pathogenic anaerobes are occasionally found shortly after death. Normal wounds (healing) of the horse frequently contain anaerobes as well as aerobes. Novy's bacillus was identified in 21% of the cases examined, parasymptomatic anthrax bacilli in 7%, Fraenkel's gas bacillus in about 29%, *Bacillus amylobacter* in 21%, and *B. putrificus verrucosus* in 7% of the cases; however, no gas edema occurred, so that determination of the presence of pathogenic anaerobes is not sufficient for such a diagnosis.—*Author's summary* (*transl.*).

10479. SCHOUPPE, KARL. Sind die Spirillen die Erreger des sogenannten Hufkrebses? *Wiener Tierärztl. Monatsschr.* 18(19): 592-594. 1931.—It is concluded that spirilla are not the cause of "hoof cancer," since they were not found in increased numbers in newly attacked regions and were found only in the surface layers of infected tissue. They are thus regarded as saprophytes living in diseased tissues and exudates.

10480. SCHÜTT, G. Ein Beitrag zur Ätiologie der Eileitererkrankung des Huhnes. *Miessner-Festschrift* p. 195-206. Fritz Eberlein: Hannover, 1930.—Oviduct disease (dropsy) in chickens arises from overfeeding. The young hens become too fat and the passage of the egg through the oviduct causes inflammation. In heavy producers, the mechanism may become damaged and result in oviduct illness. In birds with a weak constitution, irregularities and injuries may appear in the egg apparatus.—*Author's summary* (*transl.*).

10481. SEELEMAN, M. Recent results in the field of mastitis-research, especially the combating of the streptococcus-mastitis. *Internat. Dairy Congr. Eng. Ed.* 1931 (Sect. 2): 123-124. 1931.—Summary of a paper reporting results of studies at the Prussian Dairy Institute at Kiel.

10486. YAKIMOFF, W. L., und S. N. NIKOLSKY. Zur Frage der Spirochäten bei der pustulösen Stomatitis der Pferde. *Zeitschr. Infektionskr. u. Hyg. Haustiere* 39(4): 307-310. 1 fig. 1931.—In 1930, Yakimoff and Rastjapin described a spirochaete from the mouths of horses, which they named *Spirochaeta carpanoi*. The present authors studied a spirochaete from cases of stomatitis in horses, which differs from it. It measures $4.07\text{-}14.67 \times 0.3\text{-}0.54\ \mu$, and is provisionally named *Spirochaeta stomatoequi*. It is closely associated with a fusiform organism, but the writers have not determined its significance in stomatitis, which they consider as due primarily to a filterable virus.—*L. D. Bushnell.*

GENERAL

10488. BAIRD, DUGALD, and ROBERT CRUICKSHANK. The Dick test in pregnancy and its relation to puerperal sepsis. *Lancet* 219(5593): 1009-1012. 1930.—Dick tests were done on 600 pregnant women and 500 were followed through labor and puerperium. 25% of primiparae and 21.5% of multiparae were positive. Reactions were strongest in primiparae, showing no change

in advancing age groups, while reactions became less intense with age in multiparae. High sensitivity to Dick test did not indicate increased susceptibility to puerperal sepsis and negative reactors showed as many infections as positive reactors. Difficult labor and ill health were most important causes of puerperal sepsis.—*J. H. Black.*

10489. BAJ, L. Recherches cliniques et immunologiques sur la gonoréaction. *Soc. Internaz. Microbiol. Boll. Sez. Ital.* 3(7/8): 458-459. 1931.—The gonoreaction is almost always negative in all except syphilitic individuals (2% positive). The reaction is of little value in cases of acute gonorrhea (8% positive). It gives good results in chronic gonorrhea and especially in cases of gonorrheal arthritis (85% positive), where it may be a valuable diagnostic method.

10490. BERGER, H. C. L. E., et H. S. FRENKEL. Vaccination antituberculeuse avec le BCG: État actuel de la question. *Off. Internat. Épizoot. Bull. Mens.* 3(6): 784-797. 1930.

10491. BLACK, J. H. A soluble specific carbohydrate of ragweed pollen. *Jour. Allergy* 2(3): 161-163. 1931.—Evidence is presented as showing the presence of a complex carbohydrate in ragweed [*Ambrosia trifida*] pollen. This substance reacts specifically in the skin and nasal mucosa of ragweed-sensitive individuals.—*Author's summary.*

10492. BREITNER, B. Die Bedeutung der Blutgruppen. *Naturwissenschaften* 16(45/47): 849-856. 1928.—The author presents a general review on blood groups, stressing the point that the rule of the 4 groups holds regularly and that the group property of the blood is not subject to environmental influences. Brief mention is made of the heredity of blood groups, their application to forensic medicine and anthropology, and their rôle in transfusion and transplantation. The possible relationship of blood groups with several pathologic conditions is also discussed.—*P. Levine.*

10493. BURGER, GEORGE N. Antigenic value of vaccines produced from ultra-violet killed bacteria. *Bull. Basic Sci.* [*Univ. Cincinnati*] 2(1): 55-59. 1928.—4 vaccines against *B. paratyphosus B* were prepared, using filtered or unfiltered ultraviolet light, formalin, or heat, respectively, as agents for killing the bacteria. The light filter used in the first case was a solution of lead acetate in acetic acid, of the proper concentration to cut off all rays shorter than 2700 Å. The antigenic values were compared by titrating sera obtained from rabbits injected with these vaccines. The vaccines containing bacteria killed by filtered ultraviolet or by formalin gave higher titers than did those prepared by use of unfiltered ultraviolet or of heat.—*J. L. Cameron.*

10494. CACCIA, GIACINTA. Essudati provocati ed immunità antineoplastica. [Provocative exudates and antineoplastic immunity.] *Sperimentale* 84(5/6): 505-514. 1930.—The leucocytic exudate produced by intraperitoneal injection of either Grübler's Nutrimon or minced adenocarcinoma of mice, caused in cancer mice no decrease in rate of tumor growth. Amyloidosis of spleen and liver was present. In the exudate produced in rabbits some hrs. after peritoneal injection of minced mouse cancer were found many cancer cells which had resisted the action of the leucocytes and were capable of giving rise to new tumors on injection.—*Maud L. Menten.*

10495. CALMETTE, et GUÉRIN. Vaccination antituberculeuse par le B.C.G. Le B.C.G. peut-il reprendre la virulence? *Rec. Méd. Vét. École d'Alfort* 107(9): 530-533. 1931.—"Not a single one of hundreds of scientists and practitioners who have used BCG with cattle, even in those only a few days old, giving intravenous or subcutaneous inoculations in doses of 50-100 mgm., has observed or cited a single case where the inoculation with BCG has caused tubercular lesions which could lead one to believe in a recuperation of virulence by the inoculated vaccine."—(*Transl.*)

10496. CANTANI, F. Sur la préparation d'antigènes pour la déviation du complément dans le typhus, moyennant des extrait alcooliques de foies septicémiques. *Soc. Internaz. Microbiol. Boll. Sez. Ital.* 3(7/8): 441-444. 1931.—On antigens for complement deviation in typhoid.

10497. CARVALHO, ALVIMAR de. Observações sobre a allergia tuberculinica das crianças vaccinadas pelo BCG por via oral, segundo Calmette. [Observations on tuberculin allergy among newborn infants vaccinated orally with BCG.] [With English abstract.] *Brasil-Med.* 45(28): 639-641. 1931.—From intracutaneous and cutaneous tuberculin tests on children vaccinated by BCG after birth and living thereafter in non-tuberculous environments, it is concluded that the former is by far the most delicate and that it is particularly adequate to demonstrate tuberculin allergy following BCG vaccination. Large doses of a reliable old tuberculin (1 mgm.) are to be employed. No definite influence could be detected from diluting original old tuberculin in glycerin, as it is usually found in commercial preparations.—*Author's abstract.*

10498. CHALIAPINA, K., und C. ELISSUJSKI. Scharlach-Streptokokken-Anatoxin und seine vakzinierenden Eigenschaften. *Zeitschr. Immunitätsforsch. u. Exp. Therap.* 61(1/2): 121-130. 1929.—Streptococcus filtrate kept with 0.5% formalin at 39.5° for 8 wks. yielded anatoxin with only 3-5% of the original toxicity. 2 successive vaccinations with anatoxin in children gave, on the average, 70% Dick immunity. Ease of immunization varied inversely with intensity of previously obtained skin reaction. Good sera can be obtained by immunizing horses with anatoxin. Filtrates containing much protein (blood) were detoxicated by formalin with greater difficulty than others. The anatoxin produced varied considerably in vaccinating power. Flocculation tests may be used as a control to ensure production of good anatoxin.—*L. W. Butz.*

10499. DAVANZO, I. Recherches sur le pouvoir bactéricide du sang. *Soc. Internaz. Microbiol. Boll. Sez. Ital.* 3(7/8): 463-465. 1931.—In the complex phenomenon of bactericidal action of blood, the aspecific cellular factor, i.e., phagocytosis, predominates under normal conditions, while the humoral factor is secondary and acquires a fundamental importance only under special (pathologic) conditions.

10500. DIENES, L., and E. W. SCHOENHEIT. Certain characteristics of the infectious processes in connection with the influence exerted on the immunity response. *Jour. Immunol.* 19(1): 41-61. 1930.—The tuberculin type of sensitiveness is produced in guinea pigs when egg white is injected into the testicle 24 hrs. after a large dose of a special strain (R1) of the organism has been injected at the same site. The typical tissue reaction of tuberculosis is not a prerequisite of the development of the tuberculin type of sensitiveness. This type of sensitiveness may be produced also by injecting egg white into the testicles of guinea pigs infected with smallpox vaccine. The immunity response of the animals is not influenced by inflammatory processes produced by infusorial earth, tapioca, turpentine, or with the antigenic lipoid substances or the soluble substances of tubercle bacilli.—*L. A. Barnes.*

10501. DIVELEY, REX L. Anterior poliomyelitis. A study of the acute stage with special reference to the early diagnosis and treatment. *Jour. Bone & Joint Surg.* 11(1): 100-122. 12 fig. 1929.—78% of the 85 cases in the Kansas epidemic (1923) showed good recovery from paralysis with proper treatment during the 1st and 2nd stages, as against 20% with poor treatment. Cases treated with Rosenow serum in the Kansas City, Missouri, epidemic (1925) showed a more rapid recovery, with paralysis less profound and extensive than untreated cases. The acute symptoms abated almost immediately after spinal drainage and only appeared when the spinal pressure was again raised above normal. The death rate in the treated series was much smaller than in the untreated. Experiments with monkeys showed that human convalescent serum and antistreptococcic, poliomyelitic serum of Rosenow neutralize the virus, can be used to immunize monkeys for a short period, not lasting over 6 mo., and are highly specific in treat-

ment of poliomyelitis. Better results were obtained when serum was given early. Convalescent serum was more potent.—*G. N. Ludwig.*

10502. DUCRET, SIEGFRIED. Experimentelle Untersuchungen über den Prausnitz-Küstnerschen Antikörper beim Heufieber. 15p. Inaugural-Dissertation, Universität Zürich, 1928.—After a brief discussion as to the possible identity between idiosyncrasy and anaphylaxis, the author takes up the question of the Prausnitz-Küstner tests. Positive Prausnitz-Küstner tests were obtained with hay fever sera and the commercial non-protein "pollen toxin No. 312" (Kammann) as antigen. Tests were also positive when serum and antigen were mixed and injected immediately, but were negative when the mixture was allowed to stand before injection. Inverse Prausnitz-Küstner tests were positive when the interval between injection of antigen and serum was less than 15 min. The author states that the experiments were too few for definite conclusions.—*H. L. Gruehl.*

10503. FARAGÓ, FRANZ. Nitrogenfreies Agar als serotoxinbildende Kontaktsubstanz. *Zentralbl. Bakt. I. Abt. Orig.* 121(1/2): 109-111. 1931.—No difference in Bordet's agar-serotoxin formation was observed when N-free instead of commercial agar was used in injected solution; 6 guinea pigs received 5 cc.; 1, 3 cc.; and 7, 5 cc. made with commercial agar (5 cc. guinea pig serum to 1 cc. agar solution made by adding 0.5 gm. agar to 100 cc. physiological saline).

10504. FORAN, FRANCIS L., and MEYER R. LICHTENSTEIN. A study of the reactions in nonsensitive skin of mixtures in vitro of reagin and atopen. *Jour. Allergy* 2(4): 291-292. 1931.

10505. FÖRSTER, R. Ein Beitrag zur Technik der Blutgruppenbestimmung bei serologischen Reihenuntersuchungen ("Kreuzkontrolle"). *Zeitschr. Immunitätsforsch.* 57(1/2): 130-139. 1928.—The author describes at length his modification of the method of blood grouping.—*P. Levine.*

10506. FREUND, JULES. Influence of age upon antibody formation. *Jour. Immunol.* 18(4): 315-324. 1930.—In rabbits less than 20 days old, formation of agglutinins against typhoid bacilli, of hemolysins against sheep cells, and of precipitins against horse serum and egg white is strikingly less intense than in adults immunized in the same way. A definite Arthus' phenomenon can not be produced in young rabbits immunized with horse serum or egg white. This might be due to the insufficient amount of precipitins and to the fact that the skin of young animals does not react so intensely to irritants as the skin of adults.—*J. Freund.*

10507. FROBISHER, MARTIN, Jr. An improved antigen for the complement-fixation test in yellow fever. *Amer. Jour. Hyg.* 14(1): 147-148. 1931.—Dry fat-free residue of ether-extracted livers of monkeys dying of yellow fever.

10508. GREENWOOD, M. The vaccination problem. *Jour. Roy. Statistical Soc.* 93(2): 233-270. 1930.—Though Jenner did not prove that cowpox is biologically akin to smallpox, this has since been done. The lower fatality rates from smallpox of the vaccinated are not due to different age distributions and probably only in part to differences in social class. Vaccination has been shown to confer some protection against the risk of dying from smallpox. A mathematical relation between recovery rates of vaccinated and unvaccinated is derived, which fits the observed data roughly. Vaccination "has been one of the factors, but not the sole, perhaps not the most important, factor in modifying the epidemiological history of smallpox during the last hundred years."—*J. R. Miner.*

10509. HOOKER, SANFORD B., and EDNA M. FOLLENSBY. The influence of hypersensitiveness to horse serum on the duration of local passive antitoxic immunity in man. *Jour. Immunol.* 20(4): 269-289. 1931.—The duration of local passive immunity was studied in human subjects classified according to skin reactions to scarlatinal antitoxin. The method used was that of local passive antitoxic immunization and subsequent periodic testing of the successive protected areas with toxin. The advantages of this method over those previously used in studying duration of passive immunity are discussed. 10 or 20, and in 1 case 100, neutralizing doses of antitoxin were used. The negative and delayed serum reactors held locally at least 1 neutralizing dose of antitoxin for more than 24 hrs., whereas in all immediate reactors injected with comparable doses of antitoxin, less than 1 neutralizing dose remained at 4 hrs. Evidence is offered to show that the accelerated disposal of antitoxin in the "immediate serum" reactors is an immunologic, rather than a non-specific physiologic, effect.—*E. M. Follensby.*

[Relation between Thomsen's phenomenon and the cold panhemagglutination reaction.] *Boll. Soc. Italiana Biol. Sper.* 3(1): 52-55; also in *Zeitschr. Immunitätsforsch.* 57: 287. 1928.—No essential difference was found between Thomsen's reaction and cold agglutination; the reactive agglutinin was the same in both. The conclusion of Thomsen that bacterial growth has no effect other than to increase the erythrocyte sensitivity for normal agglutinins active in the cold, is confirmed.—*Author's summary (transl. by J. B. Nelson).*

10519. LEHMANN, KARL. Untersuchungen über die Konstanz des menschlichen Isoagglutinintiters bei Gesunden und Kranken. *Acta Path. et Microbiol. Scandinavica* 5(2/3): 155-169. 1928.—Blood tests made at daily intervals for 1 mo. and at longer intervals over several yrs. on a healthy individual, showed no fluctuation in isoagglutinin titer. 34 patients with chronic diseases tested in part daily, in part at longer intervals, showed no fluctuation, nor did 95 of 100 patients with surgical conditions, in part acute suppurative inflammations, upon daily testing. 3 patients with phlegmon of the extremities, and more particularly pyosalpingitis and puerperal fever, showed a slight increase in titer.—*Author's summary (transl. by J. B. Nelson).*

10520. LEVITAN, I., D. LOKHOFF, et V. KOSMODEMIANSKI. De l'influence des injections de BCG sur les animaux infectés de tuberculose virulente. *Ann. Inst. Pasteur [Paris]* 45(6): 740-753. 1930.—In experiments on 130 guinea pigs, 42 rabbits and 2 monkeys (including controls and some animals which died of intercurrent conditions), the authors found no modification of tuberculous lesions in animals treated with BCG as compared with controls; but the average period of survival was relatively longer, and the pathologic processes tended to assume a fibrous character, particularly in the lymphatic ganglia and liver.

10521. LOEWY, ERNA. Erfahrungen mit der neuen Meinickeschen Klärungsreaktion (MKR). 6p. Dissertation. Univ. Köln, 1929.—The Meinicke clarification reaction checked with the Wassermann and with the Meinicke flocculation reaction in 89.6% of 653 sera. It was more sensitive than the Wassermann in 8.6% of cases with past histories of syphilis. Syphilis was present in all positives; the reaction is therefore specific. The test is simple and largely independent of extraneous influences, and should be preferred to the Meinicke flocculation reaction. It is recommended for laboratory practice in addition to the Wassermann.—*E. Loewy (transl. by A. F. Reith).*

10522. MELA, B. Recherches sur l'état de défense des tissus anesthésiés dans les rapports avec l'infection. *Soc. Internaz. Microbiol. Boll. Sez. Ital.* 3(7/8): 467-468. 1931.—Experiments showed that it is easier for infection to pass anaesthetised than normal tissue.

10523. [MELKIKH, A. A.] МЕЛКИХ, А. А. О кровяных группах у западных бурят. [Blood groups among western Buriats.] Иркутский Медицинский Журнал [*Irkutsk Med. Jour.*] 7(3): 5-7. 1929.—Study of 1602 Buriats (including 319 children, aged 3-15 yrs.) showed the following distribution of isoagglutinative groups: 33.3%, 20.9%, 37.5%, 8.3% for groups O, A, B, and AB, respectively. Racial index was determined as 1.8. Among women, there was a very slight preponderance of groups A and AB at the expense of O and B.

10524. MUNCE, THOMAS W., and H. A. HOFFMAN. Vaccination shock in young pigs. *N. Amer. Vet.* 11(6): 35-49. 1930.—Symptoms of shock similar to those occasionally following injection of anti-hog cholera serum in young pigs may be induced by use of clear hog serum heated to 60° C. Suckling pigs are more susceptible to shock than pigs that have been weaned. The experimental shock failed to cause death in any instance.—*R. R. Spencer.*

10525. NORDMANN, MARTIN. Local reactions in sensitized animals: Arthus phenomenon, "hyperergic inflammation." *Physiol. Rev.* 11(1): 41-62. 1931.—A critical review of literature.

10526. PARKER, JULIA T. Differentiation between some toxic substances in anaerobically produced autolysates of pneumococci (types I and II). *Jour. Exp. Med.* 49(4): 695-700. 1929.—The identity of the necrotizing and toxic properties of anaerobic autolysates of pneumococci for the lungs of young guinea pigs, was investigated. Both properties are destroyed by heating to 60° C. for 5 min. and by short exposure to O; both effects are prevented by neutralization with immune serum. However, absorption of the autolysate with red cells, which does not influence the necrotizing effect, does remove or inactivate the toxic action on the lung. Pneumococcus hemotoxin differs in that it rarely causes lung involvement when injected intratracheally.—*L. C. Havens.*

10527. PEIPERS, A. Eosinophilie und Allergie. Klinisch-experimentelle Untersuchungen über ihre Beziehungen. *Deutsch. Arch. Klin. Med.* 169(1/2): 65-74. 1930.—Of 113 asthmatics, eosinophilia (more than 4% eosinophile cells) was demonstrated in 71 cases; of these, the skin reaction was positive in 56, negative in 15. Eosinophilia was absent in 42 cases; of these, the skin reaction was positive in 27, negative in 15. An exogenous allergic asthma demonstrated by a positive skin reaction is not necessarily accompanied by eosinophilia. Rather, eosinophilia is one of the clinical manifestations of allergy and frequently even the preparation for an attack. On the other hand, in many clinically latent cases the skin reaction is positive, so that only a restricted parallelism of both symptoms can be drawn. With a negative skin reaction, eosinophilia suggests further search for an allergic etiology by other methods. Even in true allergic diseases, that diagnostically valuable symptom may be absent. Type and number of disturbing allergens apparently has no influence on eosinophilia. The author was unable to demonstrate any accumulation of eosinophile cells in positive skins. Attempts to prove the reliability of the skin reaction by eosinophilia appearing after injection of specific allergen were unsuccessful.—*H. L. Gruehl.*

10528. PHISALIX, M. Vaccination contre le venin de vipère et la rage expérimentale par les mélanges virus-venin avec virus en excès, puis par le virus rabique. *Bull. Mus. Nation. Hist. Nat. [Paris]* 1928(6): 448-450. 1928.—Vaccination against viper venin and experimental rabies by virus-venin mixtures with virus in excess, then with rabies virus.

10529. POVITZKY, OLGA R., assisted by ERLA JACKSON, and MINNIE EISNER. Diphtheria toxoid. Preparation and dosage. *Jour. Immunol.* 20(3): 247-253. 1931.—A short review is given of Ramon's results in immunization against diphtheria with toxoid during 5 yrs. As a result of intensive study of comparative results between toxin-antitoxin and toxoid in preventative work against diphtheria, toxoid has been introduced by Park in the New York City Health Department, for immunization against diphtheria in smaller children. To obtain a uniform, strong product the author is using at present a preparation of Bacto-veal (Difco Laboratories), containing also beef heart muscle and proteose peptone, in preparation of diphtheria toxin. The stronger the original toxin from which toxoid is prepared, the more antigenic units will there be per cc. of resulting toxoid. The Ramon flocculation test is used to indicate whether the toxin should be converted into toxoid. This is done only when the pooled product gives a

reaction with standard antitoxin, in ½-¾ hr. in the water bath at 55° C. U. S. P. solution of formaldehyde is added in 0.4% to the toxin. This is filtered through paper pulp and incubated 4-6 weeks at 38-39.° The more antigenic units per 1 cc. of toxoid, the smaller could be the quantity given (thus, less reaction) and the smaller the number of injections (2 instead of 3). The toxoids on the market and in different laboratories necessarily vary. To arrive at uniform results, the author advocates standardization of toxoids by the Ramon flocculation test, for the number of antigenic units per 1 cc. The vials containing the product should be so labelled and the dosage administered by antigenic units instead of by quantity of an unknown product.—*O. R. Povitzky.*

10530. POWELL, H. M., and W. A. JAMIESON. Antimeningococcic serum, with special reference to the Shwartzman reaction. *Amer. Jour. Hyg.* 14(2): 470-476. 1931.—Shwartzman neutralization tests of a group of horses treated to produce the usual antimeningococcic (agglutinating) serum showed some individuals moderately good, some very poor, and a few intermediate. By special combined immunization, i.e., by subcutaneous as well as by intravenous injection, antiserum containing a high titer of Shwartzman antibody may be obtained. In absence of critical clinical comparison on a proper group of severe cases, no adequate evidence is yet available as to the value of the Shwartzman antimeningococcus antibody in meningitis. However, there are indications that this antibody contributes to the alleviation of the toxic conditions in meningitis.—*Author's summary.*

10531. RATNER, BRET, and HELEN LEE GRUEHL. Comparison of methods used in the study of anaphylaxis. *Jour. Lab. and Clin. Med.* 16(11): 1069-1079. 1 fig. 1931.—Comparison of the intraperitoneal, respiratory and uterine strip, respectively, by the intravenous route for demonstration of anaphylaxis, was made by utilization of the "double-shock method." A modification of the Dale method for uterine strip reaction is described (animal anesthetized instead of killed). Negative or suggestive anaphylactic reactions obtained by the intraperitoneal respiratory or uterine strip methods are shown in certain instances to be positive by the intravenous method. The authors believe that the intravenous shock method properly performed is superior to all others for accurately determining a state of hypersensitiveness in guinea pigs, as well as in other animals.—*Author's summary.*

10532. REYNOLDS, FRANÇOIS H. K., JAMES STEVENS SIMMONS, and JOE H. ST. JOHN. The use of tetanus anatoxin in the protection of horses against infection by Chlostridium [sic.] tetani. *Philippine Jour. Sci.* 43(4): 611-625. 1930.—Immunization of guinea pigs against tetanus infection was easily accomplished by injection of anatoxin prepared by Ramon's technique. Precipitating, drying, and pulverizing of anatoxin resulted in complete loss of immunizing properties. Tetanus anatoxin is harmless in large doses when given to large or small animals. Results of investigation of the protection afforded horses and mules by injection of anatoxin were conflicting. In the 1st series, 2 of 3 animals were protected for at least 1 mo., 1 of 3 animals for about 6 mo., while all of 4 animals tested 1 yr. after anatoxin administration were protected and 1 developed slight symptoms of infection, but recovered. In the 2nd series, 7 horses died following injection of tetanus spores, 5½ mo. after anatoxin administration.—*Author's summary.*

10533. ROSENTHAL, L. The staining of blood-grouping sera for preservation and identification. *Jour. Lab. and Clin. Med.* 16(11): 1123-1124. 1931.—Addition of dyes protects hemagglutinating sera from bacterial contamination without affecting specificity or potency. By selecting dyes of different colors, it is easy to mark sera of various groups.—*Author's summary.*

10534. SALVIOLI, G. Action de l'éther sur la toxique tétanique libre ou liée à un tissu nerveux. *Soc. Internaz. Microbiol. Boll. Sez. Ital.* 3(7/8): 448-449. 1931.—Ether in contact with tetanus toxin for a sufficient time, makes it lose a large part of its toxicity. Ether mixed with nerve tissue and then evaporated, modifies the tissue so that it can reject from liquids containing the toxin a much greater amount of toxin than normal tissue.

10535. SCHÖBL, OTTO. The duration of antitreponematous immunity in Philippine monkeys originally conveyed by immunization with killed yaws vaccine. *Philippine Jour. Sci.* 43(4): 599-601. 1930.—Antitreponematous immunity in vaccinated monkeys that have been proved immune to skin inoculation with yaws and syphilis is of as long duration as immunity induced by infection accompanied by specific skin lesion.—*Author's summary.*

10536. SIMMS, H. S., and F. S. JONES. Lactenin—a bacteriostatic substance in milk. *Internat. Dairy Congr. Eng. Ed.* 1931 (Sect. 2): 27-28. 1931.—The name "lactenin" is applied to the substance in milk which inhibits growth of bacteria; it is not utilized by bacteria while their growth is being inhibited. Lactenin was prepared in concentrated form, and also as a dried material 200-500 times as active as dried skim milk; it retains its activity for several months if kept cool and neutral. The material contains protein and it is only with difficulty that it is obtained free from Ca and phosphate, which render it insoluble. Lactenin resists mild action with trypsin, but is easily killed by heat above 65° C.—*Author's summary.*

10537. SMYTH, FRANCIS SCOTT. The toxic fraction in certain eczema serums. *Jour. Allergy* 2(3): 173-176. 1 fig. 1931.—On intracutaneous injection, the sera from certain infants with eczema give an immediate wheal formation. In about 30 patients with eczema, studied by passive transfer, 10 showed this phenomenon. This toxicity is not related to enteral absorption of offending allergens or to alteration of colloidal properties by heat or cold. It resembles the effect of the theoretical "histamine-like" substance described by Lewis in studying the skin response to trauma; but other conditions in which there was extensive skin injury failed to show similar toxicity in the serum.—*Author's summary.*

10538. SMYTH, FRANCIS SCOTT, and KATHERINE BAIN. A study of the allergic skin-test substance. *Jour. Allergy* 2(3): 177-180. 1931.—Treating the serum from patients giving positive skin tests, with saturated $(NH_4)_2SO_4$, the essential antibody fraction is precipitated with globulins. The albumin fraction is without sensitizing power, as judged by passive transfer; precipitated globulins, when dialyzed and redissolved, are potent. While passive transfer offers a poor means of estimating the titer of this antibody, it is apparently possible to concentrate the substance. It is found associated with pseudoglobulin, not with euglobulin, and the non-essential lipoidal substances may be eliminated by prolonged cold-storage of the serum before treatment with $(NH_4)_2SO_4$. In many respects the antibody substance behaves like the antitoxin of diphtheria, save in its relative heat lability.—*Author's summary.*

10544. **TAUB, SAMUEL J., and CLEVELAND WHITE.** Urticaria due to grass pollen. *Jour. Allergy* 2(3): 186-188. 1 fig. 1931.—Case report.

10545. **THOMSEN, OLUF.** Om Muligheden af phaenotypisk Undertrykkelse af et dominant Blodtypeanlaeg. [Possibility of phenotypical suppression of a dominant blood-group gene.] *Hospitalstidende* [*Copenhagen*] 71 (28): 727-743. 1928.—A discussion of whether the blood-corpuscle receptor (A or B) depending on the blood-group genes A or B, can be suppressed in the phenotype. The cases of an AB-mother with O-offspring or of an O-mother with AB-offspring quoted in literature, are subjected to examination. It must be supposed that all these cases are due to erroneous grouping and not to absence of receptor development. Still, now and again are found "defective groups," such as, for instance, Oα or Oβ, although, according to familial investigations, this is a question of agglutinin defect and not of B- or A-receptor.—*O. Thomsen.*

10546. **THOMSEN, OLUF.** Über die Beziehungen zwischen den Landsteinerschen isoagglutinatorischen Blutgruppen und Krankheit. *Seuchenbekämpfung* 6(4): 209-214. 1929.—The author discusses the work of Amsel and Halber who report that the Wassermann reaction under therapy becomes negative more readily in luetics of group O than in those of other groups. He then presents a criticism of the claims of the Hirszfelds on the conjoined inheritance of blood group and susceptibility or immunity to diphtheria or scarlatina.—*P. Levine.*

10547. **THOMSEN, OLUF.** Immunisering af Mennesker med artseget Blod af andre Typer. [Immunization of man with specific blood of other types (groups).] *Ugeskr.-Laeger* [*Copenhagen*] 91(38): 776-778. 1929.—The author endeavors to determine whether rise in agglutinin titer of recipient may be brought about by repeated (5-8) parenteral (subcutaneous or intramuscular) injections of human blood of groups A or B on individuals of another group. This was not the case, hence the author has his doubts as to the genuine antigenic nature of A- and B-receptors. Now and again there is a rise in titer of isolysin, though unspecifically, for the lysin titer increases both for α and for β in O-individuals who have been treated either with A- or B-erythrocytes.—*O. Thomsen.*

France* 4 (7): 324-328. 2 fig. 1931.—6 Merinos given ground spleen (formalin-treated) from a sick sheep, later resisted a virulent inoculation; 3 controls contracted the malady in a grave form.—*Author's conclusions* (*transl.*).

10552. **DUNKIN, G. W.** Dog distemper antiserum. *Veterinary Med.* 26(11): 432-437. 2 fig. 1931.—From experimental results and a review of the literature, the author concludes that simultaneous inoculations of serum and virus promise well for protection of susceptible dogs. The duration of the immunity thus secured is, as yet, unknown, but it is considered that it should be as good as that from vaccine followed by virus. Specific treatment of distemper by antiserum (at any rate in the early stages) has come forward as a practical measure.

10553. **GEIGER, W.** Impfversuche bei Virusschweinepest. *Miessner-Festschrift* p. 71-85. Fritz Eberlein: Hannover, 1930.—Results show that in recently infected cases of hog cholera, vaccination with double serum doses leads to a cure or to immunity in $\frac{2}{3}$ of the cases. Simultaneous vaccination of fever-free hogs under infected conditions works better the earlier it is carried out. Virulent virus, especially, causes quick and active immunity with slight losses. Simultaneous infection of sick hogs should be done with a higher serum dose than ordinary; this seems to aid production of antibodies. Simultaneous vaccination of fever-free hogs is preferable, but even in sick hogs it is not disadvantageous if the dose is sufficient, if the virus is highly virulent, and if the hogs are free from other infections, such as pneumonia.—*From author's conclusions* (*transl.*).

10555. **IKEDA, TAKEO.** Die Nachpruefungsergebnisse der serochemischen Diagnostik von Makimura für infectiöse Blutarmut des Pferdes. [In Japanese, with German summary.] *Jour. Jap. Soc. Vet. Sci.* 10(3): 269-272. 1931.—1 of 32 sera from anemic horses and 5 of 57 sera from normals or those immunized by diphtheria toxin, gave a + reaction. It is thus concluded that this method is not usable.—*Author's summary* (*transl.*).

10556. **KARSTEN.** Über die Feststellung des seuchenhaften Verkalbens durch den Nachweis von Agglutininen und komplementablenkenden Ambozeptoren im Milchserum der Kühe. *Deutsche Tierärztl. Wochenschr.* 39 (36): 561-567. 1931.—In the milk serum of infected cows, specific antibodies are generally present—agglutinins and complement-fixing amboceptors. Experiments show that an agglutination titer of 1:10 is to be considered positive; 1:5, doubtful. Cows whose milk serum completely binds (or almost so) complement in amounts of 0.3 cc. must be considered as infected. Milk serum which is sour or not entirely clear is unsuited for the complement-fixation method. Curdled milk hindered the determination of agglutination. Milk samples to be used for the test can be preserved by a small addition of formalin or boric acid, but are not quite so good. If the serum agglutinates abortion bacteria, the cows are infected.—*From author's summary* (*transl.*).

10557. **KONNO, T.** Über agglutinatorisches Verhalten von Stämmen des Bact. bronchisepticum, welche aus

Hunden, Kaninchen und Meerschweinchen isoliert wurden. *Miessner-Festschrift* p. 103-112. Fritz Eberlein: Hannover, 1930.—39 strains were examined, using 3 series of immune sera. All the strains could be considered as a unit when fresh cultures were agglutinated with the sera, but when agglutination was carried out with heated cultures, they fell into 4 types.—*From author's summary (transl.)*.

10558. KÖSER, A. Die Bedeutung der Agglutination beim seuchenhaften Verfohlen. *Miessner-Festschrift* p. 95-102. Fritz Eberlein: Hannover, 1930.—Specific agglutinins for *Bact. abortus equi* can appear as the result of vaccination or infection. These agglutinins are demonstrable in the blood of many animals at least 8-12 mo. after infection.—*Author's conclusions (transl.)*.

10559. MICHALKA, J. Über die Auswirkungen der Simultanimpfung gegen Schweinepest in Zucht- und Mastbeständen. Zugleich ein Beitrag zur Frage der Virusträger bei der Schweinepest. *Arch. Wiss. u. Prakt. Tierheilk.* 63(6): 529-542. 1931.—It is concluded from experiments and observation that simultaneous vaccination is the most reliable method to check an epizootic. It is better adapted to save fattening stock than breeding stock, since the breeding value, because of the large number of virus carriers, is distinctly lessened. At the simultaneous vaccination, all animals must be vaccinated, including pregnant and nursing sows as well as sucking pigs. Sometimes the pregnant ♀♀ abort, but generally they bear at normal time. Occasionally there is a late reaction 3-4 mo. after. In 76% of immunized animals, cholera virus was found in the lymph nodes up to 10 mo. after infection. This large number of virus carriers indicates that immunity in hog cholera is an infection immunity.—*From author's summary (transl.)*.

10560. MULLER, MAX. Zur Verwendbarkeit von Flockungsreaktionen bei der Diagnose der Rinder- und Geflügeltuberkulose. *Tierärztl. Rundschau* 37(40): 705-707. 1931.—Researches show that neither the Matefy precipitation reaction with $Al_2(SO_4)_3$ nor the Daranyi precipitation reaction with alcohol are suitable for diagnosis of tuberculosis in living cattle and poultry, since they failed in about 20% of the cases; and in animals not tuberculous, but parasitized, gave a + reaction in ⅓-¾ of the cases.

10561. SAINT MOULIN, L. de. À propos de la maladie du jeune âge du chien. *Ann. Méd. Vét.* [*Bruxelles*] 75 (8/9): 373-390. 1930.—The author conferred what seems to be a certain degree of immunity to distemper in puppies by use of a formol vaccine prepared by the method of G. Ramon for production of diphtheria and tetanus anatoxins. Results confirm the findings of Laidlaw and Dunkin, whose article on distemper (*Vet. Jour.*) is also here reprinted in French.—*L. de Saint Moulin (transl. by C. S. Gibbs)*.

10562. SCHUMANN. Massnahmen zur Bekämpfung der Kükenruhr. *Deutsche Tierärztl. Wochenschr.* 38(42): 669-670. 1930.—For the diagnostic agglutination test for white diarrhea of chicks, the test suspensions should be prepared from a large number of agglutinable strains preserved with 0.1% formalin and not over 8 days old. The tubes should be inoculated for 20 hrs. and the reaction determined with the agglutinoscope. A titer of 1:40 is regarded as positive.—*Author's conclusions (transl. by J. B. Nelson)*.

10563. SCHUMANN. Die Impfung in Abortusherden mit lebenden Kulturen und die angebliche Gefahr der Übertragung der Bang-Infektion auf den Menschen. *Deutsche Tierärztl. Wochenschr.* 39(36): 567-569. 1931.—From experimental work it is concluded that milk and milk products can become infected from infected herds and at times from those apparently sound. The most important source of infection is aborting cows, therefore it is important to avoid infection of the uterus. Immunity can be obtained only by vaccinating with living organisms; if properly done, it did not increase the danger of milk infections and decreased the average annual abortions from 22% to 2.2%. A prerequisite for success is a systematic vaccination of the herd when not pregnant as well as careful observance of hygienic measures.—*Author's summary (transl.)*.

10564. SMITH, THEOBALD. The immunological significance of colostrum. III. Intranuclear bodies in renal disease of calves. *Jour. Exp. Med.* 51(4): 519-529. 2 pl. 1930.—In the experiments reported, newborn calves were fed several times with cow serum, usually mixed with cow's milk, in place of colostrum. When necropsies were done, intranuclear bodies were seen both in an otherwise still normal kidney and in the organ markedly altered. In the latter, the renal lesions were chiefly the result of obstructive processes. In all cases these intranuclear bodies were made up of roundish disc-like units, 1-2 μ in diam., fused together in irregular masses. Sometimes these bodies were formed of as many as 12 such discs. They were not materially affected by weak acids or alkalies and for the most part occurred in the epithelium of Henle's loops, less frequently in the convoluted tubules.—*F. W. Hachtel*.

10565. THOMOFF, ZWETAN. Die Blutgruppen des Pferdes. *Arch. Wiss. u. Prakt. Tierheilk.* 61(5): 433-444. 1930.—In horses, as in man, 4 blood groups are demonstrable: O$\alpha\beta$, Aβ, Bα, and ABo. Agglutinogens do not vary, but isoagglutinins and isohemolysins have a lower titer, and it is often difficult or impossible to demonstrate them by the usual methods. Of 100 horses of various races examined in Sofia, 12% belonged to group O, 70% to A, 5% to B, and 13% to AB. The β agglutinin could be demonstrated in 67% of group O bloods and in 77% of group A bloods. The α agglutinin, on the other hand, could be demonstrated in 100% of group O bloods and in 80% of group B bloods. The blood group of a horse can be determined with the aid of 2 potent normal sera of groups Aβ and Bα. Attempts to produce test sera by immunization did not succeed, because of the appearance of non-specific agglutinins.—*Author's summary (transl. by A. S. Wiener)*.

10566. WYNOHRADNYK, VL. Un moyen rapide de diagnostic post mortem de la typhose aviaire. *Arch. Vet.* [*Bucureşti*] 22(3/6): 101-104. 1930.—The author found that the agglutination test made with 1 drop each of pericardial fluid and avian typhoid antigen establishes a rapid (5 min.) diagnosis of avian typhoid, and is clear, reliable and practical.—*Author's conclusions (transl.)*.

ANIMAL IMMUNOLOGY

PARASITOLOGICAL

(See also in this issue Entries 10560, 10606, 10619)

10567. DENNIE, CHARLES C., HARRY M. GILKEY, and SIDNEY F. PAKULA. The antisyphilitic action of the malarial parasite in other than central nervous system syphilis. *Amer. Jour. Syphilis* 15(3): 320-332. 18 fig. 1931.—Malaria treatment with improvement is reported in 2 cases of bone and joint syphilis, 3 of syphilitic interstitial keratitis, and 1 of leproid syphilis; in 2 of these the malaria produced no fever, yet the benefit was pronounced. The authors believe that the malarial parasite itself (and not the hyperpyrexia) antagonizes *Spirochaeta pallida* by stimulating production and action of macrophages.

10568. McCOY, O. R. Immunity reactions of the dog against hookworm (Ancylostoma caninum) under conditions of repeated infection. *Amer. Jour. Hyg.* 14(2): 268-303. 1931.—18 dogs were given repeated infections

with *A. caninum*, and the infections followed by egg count, hemoglobin content of blood, and recovery of adult worms from feces. In the 6 cases of heavy infection, the egg count rose rapidly during the first 3 months to a peak of several million eggs per day. The dogs became very anemic, hemoglobin dropping as low as 25%; 2 dogs died, but in 4 others a crisis occurred and the egg count suddenly dropped to a comparatively low level, though large doses of larvae were still being given, while large numbers of adult worms were passed in the feces and the hemoglobin gradually rose to normal. The fact that at the height of infection, these dogs not only resisted development of more larvae but also threw off the majority of worms already established, is interpreted as an immunity reaction. It was not absolute because 2 of the dogs, after losing their infections, were subsequently given 2nd and even 3rd infections which were thrown off in the same manner as, and more rapidly than, the 1st. In light infections, it was difficult to separate acquired immunity from age resistance, but previous infection apparently conferred some degree of immunity. In all cases tested, worms were still present in the intestines. 6 cats repeatedly infected with a cat strain of *A. caninum*, also showed increased resistance, apparently distinct from age effect. Egg production per ♀ worm in 10 of the resistant dogs autopsied at the end of the experiment, averaged 5,360 ± 313 eggs per day, or only about ⅓ the normal figure. Apparently, the conditions in the host preventing development of larvae and causing loss of the majority of worms, also greatly decreased egg production in those persisting. Nearly 2,600 worms were recovered from the feces of 7 dogs during the experiments, and the evidence from correlation with drop in egg count indicates that this figure represented approximately ½ of the worms actually lost. Occurrence and degree of eosinophilia were variable and could not be directly correlated with development of resistance.—*Author's summary.*

10569. McCOY, O. R. Immunity of rats to reinfection with Trichinella spiralis. *Amer. Jour. Hyg.* 14(2): 484-494. 1931.—Rats given sublethal doses of *T. spiralis* (known quantities of larvae) developed immunity, strikingly shown in an experiment in which 10 of 11 previously infected rats survived a test dose of larvae which killed 9 of 11 controls. Previously infected rats withstood more than twice the dose of larvae proving lethal to the majority of controls. The proportion of larvae developing to the adult stage in controls was approximately 10 times that in previously infected rats. Furthermore, the few worms developing in "immune" rats were lost from the intestine before new infection of the muscles was accomplished.

10570. TALIAFERRO, WILLIAM H., PAUL R. CANNON, and SARA GOODLOE. The resistance of rats to infection with Trypanosoma lewisi as affected by splenectomy. *Amer. Jour. Hyg.* 14(1): 1-37. 1931.—In 35 young, *Bartonella*-free rats, splenectomy from 7 days prior, to 41 days after, infection with *T. lewisi* did not markedly affect reproduction of trypanosomes as compared to that in 20 non-splenectomized controls. In decided contrast, splenectomy in a similar series of 33 young, *Bartonella*-infected rats sometimes markedly affected the normal cycle of trypanosome reproduction, so that it was longer or recurred. In general, the effect of splenectomy was slight when performed 6 days prior to infection, was more marked when performed on the same day, was pronounced when performed 5-10 days afterwards, and was very slight or nil when performed 21-58 days after infection. A series of 20 old *Bartonella*-infected animals gave results similar to those with young rats. In general, there was some effect when the operation was performed 4 days and 1 day prior to infection, and 5 days after infection; there was no demonstrable effect when the operation was performed 10-23 days after infection, but a pronounced effect when performed 41 and 60 days afterwards. Within the limits of the series, age of host per se apparently did not influence the effectiveness of splenectomy. The authors conclude that when the antibody titer which inhibits reproduction of the trypanosomes is high, the effect of splenectomy may be obscured, since the higher the titer the greater the "margin of safety" in macrophage balance. Once the balance between activity of the macrophage system and infection is disturbed by splenectomy, *Bartonella* infection, paratyphoid infection, India ink blockade, and gestation may affect formation of the reproduction-inhibiting antibody. Splenectomy influences formation of the trypanocidal antibody associated with termination of the infection, as shown by length of infection. This effect is probably more marked when there is a concomitant *Bartonella* infection. Castration performed with about the same operative trauma as splenectomy, is without demonstrable effect on *T. lewisi* infections. Infection with *T. lewisi* in *Bartonella*-free rats produces a significant increase in spleen size and demonstrable histological increase in cellular activity. Splenomegaly is more pronounced in rats with *Bartonella* alone than in those with *T. lewisi* alone, and more pronounced in rats with both infections together than in those with either alone. Increase in spleen size resulting from *T. lewisi* infection occurs within the 1st few days of infection, after which there is no progressive change in size. In those rats which died during infection with *T. lewisi*, death could be correlated with a *Bartonella* or paratyphoid infection, without assuming any pathogenicity of the trypanosomes.

10571. WHARTON, DENIS R. A. Skin reactions in rabbits infected with the larval form of Taenia serrata. *Amer. Jour. Hyg.* 14(2): 477-483. 1931.—Of 182 stock rabbits examined, 81 were found naturally infected with *Cysticercus pisiformis*, the larval form of *T. serrata* usually in the omentum and with little ill effect on the host. Of 16 artificially infected rabbits, many display liver involvement; passage of young larvae through the liver frequently caused mechanical obstruction or injury to the ducts and vessels, or pollution of the blood stream with products of metabolism, and death. Skin tests were performed on 30 rabbits with 0.1 cc. of the supernatant fluid from a 1% extract of the powder of various worms in saline after incubation at 37° C. for ½ hr. and at room temp. for 15 min. Of 18 rabbits either naturally or experimentally infected with the larval form of *T. serrata* but with no other worm, 13 gave + and 5 — reactions to the larval form of the specific antigen, and 15 + and 3 — reactions to the adult form. 2 of the 3 — reactions occurred in rabbits heavily infected that they may have been desensitized. Failure to react to either larval or adult forms of the specific antigen was observed in only 1 infected rabbit which contained a single larva in the liver. When several of these rabbits were tested with *Moniezia, Cysticercus fasciolaris*, or *Macracanthorhynchus*, they gave uniformly — tests. Uniformly — tests were obtained with these antigens in 12 uninfected rabbits.

PARASITOLOGY (ANIMAL)

10572. ACKERT, JAMES E., MARIAN FISHER McILVAINE, and NAOMI ZIMMERMAN CRAWFORD. Resistance of chickens to parasitism affected by vitamin A. *Amer. Jour. Hyg.* 13(1): 320-336. 1931.—White leghorn chickens (60) 7-8 wks. old in 2 preliminary tests and 127 chickens 4-7 wks. old in 4 experiments were used to ascertain whether resistance to *Ascaridia lineata* (Schneider) was affected by vitamin A (from cod-liver oil) in the diet, the criteria being the numbers and the lengths of worms remaining in the intestines at the close of the experiment. During the 5-wk. periods of the experiments the characteristic avitaminosis A eye disease, ophthalmia, occurred repeatedly among the chickens on the vitamin A-deficient diet but was wholly absent from those on the diets adequate for this vitamin. Significantly larger numbers of *A. lineata* remained in the chickens of group I (diet deficient in vitamin A) than in those of groups II and III (diets adequate for vitamin A). The average total worm length per chicken was significantly greater in group I than from the chickens of groups II or III. The larger numbers of *A. lineata* remaining in the chickens of group I was attributed in part to evidence of weakened peristalsis observed in most of the chickens on the vitamin A-deficient diet, thus making it less difficult for the young worms to withstand the rigors of peristalsis. Concerning lengths of worms, if bacteria constitute a regular portion of the diet of *A. lineata*, the sluggish intestines of the vitamin A-deficient chickens should afford richer bacterial cultures, and thus possibly facilitate more rapid growth.

10573. ACKERT, JAMES E., and L. O. NOLF. Resistance of chickens to parasitism affected by vitamin B. *Amer. Jour. Hyg.* 13(1): 337-344. 1931.—Groups of chickens given the same number of embryonated eggs of *Ascaridia lineata* (Schneider) had more worms when their diets lacked vitamin B than did similar groups of chickens whose rations contained adequate amounts of this vitamin (from baker's yeast). The larger numbers of worms are attributed in part to partial paralysis of the intestine due to lack of vitamin B, the greatly weakened peristalsis probably aiding the worms in remaining in their habitat. Larger specimens of *A. lineata* were found in those chickens whose diet contained yeast than in those lacking it. It is suggested that the yeast may contain a factor favorable to the growth of the worms.—*From authors' summary.*

10574. [ALFEEVA, S. P.] АЛФЕЕВА, С. П. К вопросу о миграции аскарид и остриц в ткани кишечной опухоли у человека. (On the question of the migration of Ascaris and Oxyuris into the tissues of intestinal tumors in man.) Вестник Микробиологии и Эпидемиологии (*Rev. Microbiol. et Épidémiol.*) 6(4): 423-432. [English summary, p. 476.] 1927.—In a case of acute perforative peritonitis, autopsy revealed an *Ascaris* in the peritoneal cavity. In the wall of the ileum was found a leiomyoma. In the peripheral parts of the tumor (up to 2-3 cm. thick) were passages of various standing—old ones, pigmented and filled in with scar tissue, and more recent with distended blood vessels going along the passage, with a slight cellular infiltration of the tissue of the tumor, even with fibrinous deposit in some places. One passage, bearing features of acute inflammatory process on its walls, came up to the surface of the tumor and communicated with the peritoneal cavity. Inflammatory alterations of the peritoneum in the vicinity of this passage as compared with its more remote parts supported the surmise that this was the place where the *Ascaris* found in the peritoneal cavity had passed and where the exudative peritonitis had begun. In one of the passages was discovered *Oxyuris vermicularis*, in another the remains of a dead calcified parasite, probably *Ascaris*.

10575. [ANANIAN, S. A.] АНАНЯН, С. А. К вопросу о тениидозах населения Армении с анализом морфологической изменчивости элементов их возбудителей. [Taeniasis of the Armenian population and morphological analysis of the parasites.] Русский Журнал Тропической Медицины, Медицинской и Ветеринарной Паразитологии [*Russ. Jour. Trop. Med., Med. & Vet. Parasitol.*] 7(9): 604-609. 1929.—Statistics show a cestode incidence in 11.9% out of 3000 observations. *Taenia solium* was found in 0.46% of all cases. *Taeniarhynchus saginatus* in 44.54%. Morphological studies were made, with special attention to the comparative sizes of scolices and proglottides. In *Taeniarhynchus saginatus* the small rudimentary proboscis, an atavistic vestigial organ, was found in 20% of all specimens examined. Pigmentation of the scolices was found in 37%. *Taenia solium* grew less intensively and was usually much smaller than *T. saginatus*.

10576. [BADANIN, N. V.] БАДАНИН, Н. В. К обнаружению Gastrodiscoides hominis—паразита человека у дикого кабана. [Gastrodiscoides hominis in a wild boar of Kazakstan.] [French summary.] Русский Журнал Тропической Медицины, Медицинской и Ветеринарной Паразитологии [*Russ. Jour. Trop. Med., Med. & Vet. Parasitol.*] 7(8): 514-516. 2 fig. 1929.—*G. hominis* was found in the large intestine; it is the first record of this parasite in U.S.S.R. A detailed description is given of the egg and of the 3 specimens. Since, as a rule, whenever this parasite has been discovered in swine it has been found also in humans of the locality, there is reason to suppose that it may be found also in the population of Kazakstan.

10577. BAYLIS, H. A. Notes on some parasitic worms from Norwegian rodents. *Ann. and Mag. Nat. Hist.* 7 (38): 175-176. 1931.—First record of *Protospirura muris* in a vole, *Evotomys rutilus*. Some hosts were collected at Finmark, Immerfoss, Upper Reisendal and Tromsö Province; as human habitations here are very few and miles apart, some other insect than the usual *Tenebrio* may act as intermediate host. A cysticercus, "*Cysticercus innominatus hypudaei*," was found on the liver of *Evotomys rufocanus;* and a cestode, probably a species of *Paranoplocephala*, was found on 2 occasions in the intestines of *Microtus ratticeps*, at Finmark.

10578. BEDERKE, OTTO. Qualitative und quantitative Analyse der Helminthenfauna im Dickdarm des Pferdes. [Qualitative and quantitative analysis of helminth fauna in the large intestine of the horse.] *Berliner Tierärztl. Wochenschr.* 47(10): 149-150. 1930.

10579. [BOGOÏAVLENSKIÏ, N. A., S. N. KARLENKO, and G. K. SHKHÏAN.] БОГОЯВЛЕНСКИЙ, Н. А., С. Н. КАРЛЕНКО, и Г. К. ШХЯН. К вопросу о кокцидионосительстве у овец Казахского уезда (в Азербайджане). [Coccidia carriers among the sheep of Kazakh district, Azerbaijan.] [French summary.] Русский Журнал Тропической Медицины, Медицинской и Ветеринарной Паразитологии [*Russ. Jour. Trop. Med., Med. and Vet. Parasitol.*] 7(2): 102-105. 2 fig. 1929.—In 127 out of 300 sheep, fecal examination revealed coccidia—*Eimeria faurei* and *E. intricata*. Only 2.3% showed pure coccidial invasion, the rest had it combined with worms. Since anamnesis revealed no pathological symptoms, the authors consider this a case of coccidia carriers, and not of coccidiosis.

10580. [BUDYLIN, V. G., and V. V. ANDREEVA.]

БУДЫЛИН, В. Г., и В. В. АНДРЕЕВА. Материалы к характеристике гельминтофауны Азербайджана. [Helminth fauna of Azerbaijan.] Русский Журнал Тропической Медицины, Медицинской и Ветеринарной Паразитологии [*Russ. Jour. Trop. Med., Med. and Vet. Parasitol.*] 7(6): 390-393. 2 pl. 1929.—Fecal examinations were made in the Transcaucasian district of Agdam, using the Fülleborn method. No perianal grattage could be performed, thus rendering data about *Enterobius vermicularis* and *Taenia saginata* only relatively correct. Of 2162 persons, 1517 were infected, *Trichocephalus trichiurus* predominating (1315 cases). Altogether 9 species were discovered. Double and triple invasion was very frequent, and there were several hosts harboring 4 and even 5 species at once. *Trichostrongylus* was found in 9.8%.

10581. **CARPANO, MATTEO.** Sulla trasmissione della febbre della costa orientale (theileriosi da Theileria parva) a mezzo del sangue circolante e qualche considerazione sulla differenziazione della Theileria parva dalla Theileria annulata. [Transmission of Oriental coast fever (Theileria parva theileriasis) by means of circulating blood and some considerations upon the differentiation between T. parva and T. annulata.] *Clinica Veterinaria* 53(5): 261-268. 2 fig. 1930.—The author obtained for the first time (1912) experimental transmission of Oriental coast fever of bovine cattle. The same transmission has been observed in French N. Africa, by Sergent, Donatieu, Parrot, Lestoguard and Plantureau (1926), and in S. Africa by Theiler and Du Toit (1928). The success of the experiment is ascribed to the presence of the plasmatic bodies of Koch in the circulating blood. The gravity of the experimental disease seems to depend on the peculiar sensibility of the inoculated animal. *Theileria parva* and *T. annulata* differ in morphology and in geographic distribution. Other similar affections, such as that produced by *Theileria dispar* are distinct.—*M. Carpano* (*transl. by A. Agramonte*).

10582. [CHERKASOV, A. V.] ЧЕРКАСОВ, А. В. К вопросу о распространении глист среди детского населения г. Киева по данным клиники за 1922-26 г. [Helminthiasis among children in Kiev in 1922-26.] Русский Журнал Тропической Медицины, Медицинской и Ветеринарной Паразитологии [*Russ. Jour. Trop. Med., Med. and Vet. Parasitol.*] 7(5): 332-337. 1929.—Helminthological examination was conducted from 1922 to 1926 on 506 boys and 361 girls, infection being 72.31% and 81.44% respectively. These data do not include children who entered the clinic with helminthological complaints, but are taken from the normal pediatrical division. Double and triple invasion was rarer than single. *Ascaris lumbricoides* was found in 57.32%; *Trichocephalus trichiura* in 36%; *Enterobius vermicularis* in 17.64%; Cestoda in 1.5%. Eosinophilia (above 6%) was found in 371 cases; decrease of hemoglobin in 91 cases. Majority had more or less pronounced leucocytosis; true leucocytosis was found in 13 cases. Lymphocytosis was present in 442 cases (66%). No particular stool disorders, due to helminthiasis, were noticed.

10583. [DANIL'CHENKO, A. T.] ДАНИЛЬЧЕНКО, А. Т. К вопросу о возможности заражения некоторыми видами глист посредством овощей с одесских полей орошения. [Possibility of helminthological infection through vegetables from the irrigation fields of Odessa.] [German summary.] Одеський Медичний Журнал (*Odessaer Med. Zeitschr.*) 5(1/2): 88-106. 1930.—Feces of 200 persons dwelling or working in the vegetable-growing fields irrigated with sewage waters from Odessa were investigated; 95.5% contained *Trichuris trichiura*, 30% *Ascaris lumbricoides*, and 5% *Hymenolepis nana*. Living quarters and conditions were highly insanitary, not counting the practically direct contact with the sewage waters. These waters were examined by a special method, since neither Telemann nor Fülleborn methods proved quite adequate. Strong solutions of Fe_2Cl_6 and Na_2CO_3 were added to sewage water, and a few hours later the sediments were extracted and examined after Fülleborn and Telemann methods. As a rule, in each preparation were found 18-20 eggs of *T. trichiura*, less often 1-2 eggs of *A. lumbricoides*, and even more seldom those of *H. nana*, *Taenia solium* or *Taenia saginata*. According to published data, eggs of these parasites survive 12-16 weeks. Therefore, both the general infection of the workers and the high egg contents of the sewage waters corroborate the author's hypothesis that the high percentage of *T. trichiura* invasion among the natives of Odessa is largely due to the wide use of vegetables from the irrigation fields.

10584. [DIMITRIU, E. A.] ДИМИТРИУ, Е. А. К изучению глистных инвазий среди рабочих Победенского рудника. [Helminthiasis among Pobedenski miners.] Русский Журнал Тропической Медицины [*Russ. Jour. Trop. Med., Med. and Vet. Parasitol.*] 7 (2): 137-139. 1929.—488 miners were examined (Fülleborn method and smear) and 73.5% found positive for worms: *Ascaris lumbricoides*, 55.5%; *Trichuris trichiura*, 20.2%; *Enterobius vermicularis*, 10%; *Hymenolepis nana*, 2.6%; Taeniidae, 1.6%; *Rhabditis* sp., 0.4%; *Dicrocoelium lanceatum*, 0.2%. Invasion among surface workers, 58.3%; among underground workers, 75.2%. Out of 150 members of miners' families, 60.6% were positive for worms. Conditions of work and water supply were highly insanitary.

10585. **EHLERS, G. H.** The anthelmintic treatment of infestations of the badger with spirurids (Physaloptera sp.). *Jour. Amer. Vet. Med. Assoc.* 31(1): 79-87. 1931.—Arecolin hydrobromide, santonin, oil of chenopodium, and CCl_4 seemed to be ineffective. Tetrachlorethylene in large dose was 100% effective, but also killed the badger; in a 10-minim dose it was not effective. CS_2 was very effective, the badgers improving very promptly; postmortems were not made immediately following treatment to determine whether it was 100% effective; there were no fatalities among the 54 badgers treated.

10586. **FAUST, ERNEST CARROLL.** Animal parasites of wild and domestic mammals and their relationship to human welfare. *Sci. Month.* 32(3): 228-234. 1931.

10587. **FENG, L. C.** Studies on tissue lesions produced by helminths. *Arch. Schiffs- u. Tropen-Hyg.* 35 (1): 1-10. 1931.—Lesions were studied produced by the cestodes *Hymenolepis erinacei* from *Erinaceus dealbatus*, *Hymenolepis nana* from *Cricetulus griseus*, an undesignated worm from *Phoenicopterus roseus*, *Rallietina echinobothrida* from *Gallus gallus*, and the plerocercoid of *Diphyllobothrium latum* from *Lota vulgaris*; by the trematodes *Cotylurus platycephalus* from *Larus ridibundus*, *C. cornutus* from *Anas boschas*, and *Chaunocephalus* sp. from *Ciconia* sp.; and by the nematodes *Physaloptera clausa* from *Erinaceus dealbatus* and *P. caucasica* from *Hamadryas hamadryas*. These include types with intra- and extra-intestinal digestion of the host tissue.—*E. C. Faust.*

10588. **FÜLLEBORN, FRIEDRICH.** Wanderung der Nematodenlarven im Körper des Wirtes. *Naturwissenschaften* 19(4): 79-82. 1931.—The larvae of the hookworm, *Strongyloides stercoralis*, and *Ascaris* penetrate the skin or the walls of the gastro-intestinal tract to go to the lungs by the blood stream and pass from there by way of the trachea to the esophagus and the gastro-intestinal tract, where they become sexually mature. More seldom they pass out of the lungs, through the lung veins, to the left heart with whose blood they form emboli in all the organs. After the larvae get into the circulation their transportation is purely mechanical since the anatomy of the host determines their course; also the ascent in the trachea is brought about by the ciliated epithelium of the host. An attempt was made to explain these migrations phylogenetically. *Oxyuris* larvae obviously do not migrate. Observations on the special clinical symptoms of *Ascaris* larval migration are included.—*H. E. Essex.*

10589. **GOIFFON, R.** L'Entamoeba coli, signe de stagnation colique droite. *Arch. Malad. Appar. Digest. et*

Malad. Nutrit. 20(8): 964-968. 1 fig. 1930.—For 10 yrs. Goiffon has found his diagnosis of stagnation of the colon, based on the presence of *E. coli*, confirmed by other means whenever made.

10590. [GORDINA, R. V.] ГОРДИНА, Р. В. Быстрота всплывания и оседания яиц некоторых видов глист при исследовании кала по методу Фюллеборна. [Time element in the process of flotation and sedimentation of some tapeworm eggs in Fülleborn's method of stool analysis.] [German summary.] Одеський Медичний Журнал (*Odessaer Med. Zeitschr.*) 5(1/2): 175-186. 1930.—Eggs of *Hymenolepis nana* and *Trichuris trichiura* remain on the surface even after standing for several days in the salt-saturated solution. Number of eggs of *Ascaris lumbricoides* increases in the surface film for at least a month. In negative cases, a repeated analysis 6-12 hrs. later may reveal eggs of *A. lumbricoides*, which accumulate more and more as time goes on. Thus, in *T. trichiura*, the number of eggs on the surface after 96 hrs. is hardly equal to that after 2 hrs., whereas with *A. lumbricoides* the number 96 hrs. later is almost twice the number seen after the first 2 hrs. Eggs of *Enterobius vermicularis* reached their highest accumulation in 2 hrs., then steadily decreased, practically disappearing from the surface 72 hrs. later. However, they are not deposited at the bottom, and their fate as well as their disappearance are unexplained. Eggs of all the aforementioned spp. appear on the surface within 10 min. The author observed repeatedly the tendency of the eggs to gather at the periphery of the surface, and, therefore, advises taking samples from the periphery, not from the center.

10591. GOUREVITSCH, D. Zur Frage der Pathogenität der Lamblien und Trichomonas bei Kindern und der Therapie mit Myosalvarsan. *Arch. Schiffs- u. Tropen-Hyg.* 35(1): 26-36. 1931.—*Lamblia* and *Trichomonas* are pathogenic in children, producing for the most part gastroenterologic symptoms. Myosalvarsan, because of its power to activate the cells and its parasito-tropic properties, is curative.—*E. C. Faust.*

10592. GRAWERT, und EICHMAN. Halogenierte Kohlenwasserstoffe als Leberegelmittel für Rinder. [Halogenised hydrocarbons as remedy against flukes in cattle.] *Tierärztl. Rundschau* 36(40): 679-682; (41): 693-697; (42): 714-716. 5 fig. 1930.

10593. [GROMASHEVSKII, L. V.] ГРОМАШЕВСКИЙ, Л. В. Опыт массовой гельминтологической работы в Одессе. [Helminthological mass investigation in Odessa.] [German summary.] Одеський Медичний Журнал (*Odessaer Med. Zeitschr.*) 5(1/2): 5-22. 1930.—This investigation included 4478 people—1500 adults (about 1% of the total adult population) and about 3000 children (2-3% of Odessa's children); 75.9% were found infected. Eight spp. of parasites were discovered: *Trichuris trichiura*, 71.5%; *Ascaris lumbricoides*, 10.9%; *Enterobius vermicularis*, 10.4%; *Hymenolepis nana*, 6.3%; *Ancylostoma duodenale*, 0.6%; *Taenia saginata*, 0.4%; *Taenia solium*, 0.2%; *Dibothriocephalus latus*, 0.2%. The last 4 spp. were found in isolated cases only, or else in the non-indigenous groups, e.g., 43 Chinese from Shanghai with 67.4% of invasion. *T. trichiura* is the most widely distributed parasite among the residents of Odessa—90%. Ascaris predominates among peasants and Red Army soldiers (mostly of peasant origin). *H. nana* is prevalent among children. The comparatively small percentage of *E. vermicularis* is probably due to the method of investigation (Fülleborn), which alone is insufficient to demonstrate this species; with the perianal grattage method in 269 cases, it was found in 54.6%. The distribution of the parasites supports the author's hypothesis that the predominance of *T. trichiura* among the city population is due to the use of vegetables and greens from fields irrigated with sewage.

10594. [GRUBER, L. I.] ГРУБЕР, Л. И. К вопросу об изменении крови при глистоношении. [Alteration of blood in helminthiasis.] [German summary.] Одеський Медичний Журнал (*Odessaer Med. Zeitschr.*) 5(1/2): 107-118. 1930.—Blood and feces were examined from 112 children aged 4-17. 53 harbored 1 sp. each, distributed as follows: 5 with *Enterobius vermicularis*, 9 with *Hymenolepis nana*, 14 with *Ascaris lumbricoides*, and 25 with *Trichuris trichiura*. 44 children carried 2 spp. simultaneously, in various combinations; 6 were hosts of 3 spp. at once; 9 were completely free of infection and served as controls. In the 1st group (1 species hosts) the erythrocytes were below normal in 18.9%; leucocytosis in 35.9%; decreased haemoglobin in 58.5%. Alterations in leucocytes were much more marked: neutropenia in 98.1%, eosinophilia in 84.9%, and lymphocytosis in 94.3%. The greatest changes were found in cases with *H. nana*, the smallest in those with *A. lumbricoides*. The smallest changes in leucocytes were produced by *E. vermicularis*. The hosts with 2 spp. (in which the combination with *T. trichiura* predominated) showed the same changes as the first group, only deviation from the normal was more pronounced. The 3rd group was too small to reveal any characteristic peculiarities. The control group showed normal erythrocyte and leucocyte counts; decrease of hemoglobin was found in 3 cases only, and deviation was very slight (69% in 2 cases, 66% in 1). The white elements showed very little deviation. Eosinophilia was noticed in 2 cases only, of which one suffered with bronchial asthma. The author cites 7 cases in which the helminthological examination was negative; blood examination indicated helminthiasis, which was corroborated by fecal examination.

10595. HENRARD, CONSTANT. Quelques protozoaires parasites des larves de Simulium congolais. *Rev. Zool. et Bot. Africaines* 19(2): 226-230. 1930.—*Thelohania multispora* Strickland, *T. fibrata* Strick., *T. bracteata* Strick., and *Coelomycidium simulii* Deb. were found in *Simulium* sp. larvae in Belgian Congo. The parasites and the tumors they cause are briefly described.

10596. HENTSCHEL, C. C. On the correlation of the life-history of the acephaline gregarine, Gonospora, with the sexual cycle of its host. II. Gonospora (Kalpidorhynchus) arenicolae. *Parasitology* 22(4): 505-509. 1930.—In general there is a correlation between the life-history of *G. arenicolae* and the sexual cycle of its host, *Arenicola ecaudata*, similar to that between *G. varia* and *Audouinia tentaculata*. In *G. arenicolae* the correlation is not so definite and the life-history of a generation of parasites does not necessarily coincide with a sexual cycle of the host. This is complicated by the double annual spawning of the host. The formation of sporocysts is simultaneous with the sexual maturity of the worm. It is suggested that, as in *Audouinia*, a secretion produced by the gonads stimulates the development of the gregarine. Ejection of the sporocysts with the gametes was observed. It is suggested that phagocytosis may be the cause of the rupture of the gametocysts in this species.—*Author's summary.*

10597. HONNA, F. Appendicitis caused by Endamoeba histolytica. *Taiwan Igakki Zasshi* [*Jour. Med. Assoc. Formosa*] 309. 87. 1930.—First report of a case of primary involvement of this pathogen in appendicitis in Japan. —*E. C. Faust.*

10598. HOROWITZ, A., J. SAUTET, et G. TERRIAL. Remarques sur le rôle pathogène de quelques protozoaires parasites intestinaux de l'homme. *Arch. Malad. Appar. Digest. et Malad. Nutrit.* 20(5): 582-599. 3 fig. 1930.—The evidence for and against the pathogenicity of certain intestinal protozoa is based on 5 cases. In 1 (a persistent, periodic diarrhea), the stools before treatment (emetine and stovarsol) contained *Entamoeba coli, Endolimax nana, Chilomastix mesnili* and *Giardia intestinalis;* after treatment and clinical cure they still contained numerous cysts of the last. In a 2nd case (indigestion and abdominal pain) the feces contained *E. coli, E. nana, Pseudolimax bütschlii, G. intestinalis,* blastocystis and yeasts; after treatment and clinical cure, the same organisms were found with the exception of *P. bütschlii.* In a 3rd case vegetative forms of *E. coli* and cysts of *G. intestinalis* and blastocystis were found before treatment but not afterward. In these 3 cases the clinical symptoms were

insignificant in comparison with the heavy intestinal infestation. In 2 other cases all the clinical symptoms of amebic dysentery were present but no parasites were found. The authors remark that the pathogenicity of a protozoan intestinal parasite is difficult either to prove or to disprove; that the supposedly pathogenic parasites are in the minority in the intestinal flora and fauna, and that when intestinal protozoa are injected into an experimental animal, the associated bacteria, yeasts, chemical substances and possible invisible viruses are injected with it.

10599. [ÏAKIMOV, V. L., V. S. BELAVIN, E. F. RASTEGAEVA, and S. N. NIKOL'SKIĬ.] ЯКИМОВ, В. Л., В. С. БЕЛАВИН, Е. Ф. РАСТЕГАЕВА, и С. Н. НИКОЛЬСКИЙ. Географическое распространение пироплазм и клещей крупного рогатого скота на Северном Кавказе. [Geographical distribution of piroplasma and mites on large horned cattle in North Caucasus.] Русский Журнал Тропической Медицины [*Russ. Jour. Trop. Med., Med. and Vet. Parasitol.*] 7 (1) : 34-35. 1929.

10600. [ÏAKIMOV, V. L., and D. B. KOLMAKOV.] ЯКИМОВ, В. Л., и Д. В. КОЛМАКОВ. О пироплазмозе северного оленя. [Piroplasmosis of Tarandus rangifer.] Русский Журнал Тропической Медицины, Медицинской и Ветеринарной Паразитологии [*Russ. Jour. Trop. Med., Med. and Vet. Parasitol.*] 7 (9) : 610-614. 1 fig. 1929.—A comparative morphological study of the parasite found in *Tarandus rangifer*, and called by Kerzelli *Piroplasma tarandi rangiferis*, and of other Piroplasmas, e.g., *Piroplasma bigeminum, Babesiella bovis, B. karelica, Françaiella colchica, F. caucasica, F. occidentalis, P. ovis*, and *F. ovis*, showed that *P. tarandi rangiferis* is characterized by: (1) central location; (2) obtuse angle of divergence of the double pear-like forms; (3) size, smaller than the radius of the erythrocyte; (4) chromatin mass, 1. From this the parasite belongs to *Babesiella*, Mesnil, 1928, although, judging by the number of its pear-like and ring-like forms, it stands halfway between this and *Françaiella* Yakimoff, 1926. And since its size is usually less than the radius of the erythrocyte, and seldom equals the latter, its place is between *Babesiella* s. str. and *Françaiella*. It is concluded that the parasite of *T. rangifer* should be known as *Françaiella tarandi rangiferis* Kerzelli, 1908.

10601. [ÏAKIMOV, V. L.] ЯКИМОВ, В. Л. К вопросу о паразитизме у пресноводных рыб. Chlamydophrys у плотвы (Rutilus rutilus.) [Parasitism in fresh water fishes. Chlamydophrys in Rutilus rutilus.] Русский Журнал Тропической Медицины, Медицинской и Ветеринарной Паразитологии [*Russ. Jour. Trop. Med., Med. and Vet. Parasitol.*] 7 (10) : 702-705. 1 fig. 1929.—In smears from the liver of *Rutilus rutilus*, from lake Pid'mozero, the author found *Chlamydophrys*, which is described. It approaches most *C. stercorea* and *C. minor*, but is about twice as large. Although found in the liver, the author supposes that originally it was located in the intestine.

10602. ILLINGWORTH, J. F. Manson's eye-worm distributed by English sparrows. *Proc. Hawaiian Ent. Soc.* 7 (3) : 461. 1931.—*Oxyspirura mansoni* is a major pest of young chicks in Hawaii, when they are allowed to run on the ground and feed on the burrowing cockroach, *Pycnoscelus surinamensis* (the intermediate host). The English sparrow [*Passer domesticus*] was also found to be a host.

10603. [ISAICHIKOV, I. M., and G. A. SHUSTER.] ИСАЙЧИКОВ, И. М., и Г. А. ШУСТЕР. К характеристике глистных заболеваний населения Омского исправдома. [Worm invasion in the reformatory inmates of Omsk.] Русский Журнал Тропической Медицины [*Russ. Jour. Trop. Med., Med. and Vet. Parasitol.*] 7 (2) : 140-142. 1929.—Of 300 inmates examined by Füllebornʼs method, 39.66% were positive. Natives of Siberia showed the lowest percentage. Next were persons temporarily living in Siberia. Highest average was shown by the exiles from European Russia, especially in *Trichocephalus trichiurus*. Ascarids predominate among temporary inhabitants, *Enterobius vermicularis* among the natives. The latter also show the highest percentage of *Taenia saginata*—due to use of raw meat.

10604. JÍROVEC, OTTO. Notizen über parasitische Protisten I. *Zentralbl. Bakt. Abt. I. Orig.* 118 (1/2) : 77-80. 5 fig. 1930.—Descriptions of parasites either insufficiently known or found in novel situations, including: *Spirochaeta noelleri* in the larvae of *Simulium reptans; S. culicis* in *Culex* larvae; spirochaetes in *Anopheles* larvae; *Cytamoeba bacterifera*, in the blood of *Rana esculenta; Lamblia ardeae* from *Podiceps nigricollis*.

10605. [KARIBOV, N.] КАРИБОВ, Н. Предварительные данные по обследованию глистных инвазий среди некоторых групп населения г. Тифлиса. [Worm infestation in Tiflis, Georgia.] Русский Журнал Тропической Медицины [*Russ. Jour. Trop. Med., Med. and Vet. Parasitol.*] 7 (1) : 45-46. 1929.—Of 189 house workers and 220 children 82.9% showed worms. The smear method was used. One parasite was found in 223 cases; 2 in 105; 3 in 10; 4 in 1. *Trichocephalus trichiuris*, 71.1%; *Ascaris lumbricoides*, 34.2%; *Enterobius vermicularis*, 2.2% (must be higher, since out of 108 perianal grattages 55.5% were positive); *Taenia*, 3.1%; *Hymenolepis nana*, 0.9%; *Strongyloides stercoralis*, 0.2%; *Ancylostoma duodenale* (first record in eastern Georgia), 1.2%; *Fasciola hepatica*, 0.7%; *Macracanthorhynchus hirundinaceus*, 0.2%. Highest percentage of infestation was in individuals under 10 years of age; lowest, over 20.

10606. KITAMURA, K. Experimental studies on dermatitis caused by hookworm larvae. [In Japanese, with English summary, p. 37-39.] *Japanese Jour. Dermatol. and Urol.* 30 (4) : 279-317. 2 pl., 12 fig. 1930.—Histologic study of the development of 5-8 day old encysted larvae of *Ancylostoma caninum* experimentally applied to the skin of dogs, and of the invasion of the dogs' skin by the larvae. They were found extended and coiled, in the horny layer, the Malpighian layer, the hair follicles, and the sweat and sebaceous glands and ducts.—*From author's summary.*

10607. KOBAYASHI, HIDEKAZU. Studies on the development of Diphyllobothrium mansoni (Cobbold, 1882) Joyeux, 1927. (Third report.) Experimental studies on the mode of infection by the mature procercoid. *Taiwan Igakki Zasshi* [*Jour. Med. Assoc. Formosa*] 30 (1) (no. 310) : 3-8. 31 fig. 1931.—Experiments were conducted on frogs, white mice, white rats, rabbits, cats, and man. In the frog the larvae when inoculated by mouth remain some time in the stomach and intestinal wall, but eventually escape into the abdominal cavity and migrate to the femoral muscles (32 days); in the mouse at the end of 25-30 days they have migrated via the abdominal and thoracic cavities to the adipose tissues of the neck. When inserted into the vagina of the mouse they migrated anteriorward through the subcutaneous tissues to the neck; when placed in the conjunctival sac they became lodged in the subcutaneous tissue on the temporal side of the posterior canthus. When placed on the unmodified, shaved, scarified or blistered skin of the mouse they penetrated into the subcutaneous tissue and at times into deeper layers. In man they reached the subcutaneous tissue, where they multiplied. Pathologic changes were principally found in the subcutaneous layers, where an infiltration of eosinophiles and other leukocytes was demonstrated around the tunnels and paths of migration.—*E. C. Faust.*

10608. KOCH, JOS. Ueber die Cellula cancrosa specifica s. parasitaria. 5. Mitteilung über die parasitäre Entstehung des Krebses. *Zentralbl. Bakt. Abt. I. Orig.* 118 (5/6) : 241-277. 3 col. pl. 1930.—In cancer alveoli there exists a second sort of cell, which in contrast to the homologous cells of the host, can only be heterologous. Its disparity is shown by its parasitic and malignant behavior. It grows within as well as without the epithelial cell itself and is nourished by the latter, which it destroys. The intracellular are chiefly the smaller and spherical forms, the extracellular have a variety of

shapes. The morphology of the supposed parasite is described. Pending the more exact terms of a classification as pathogenic protozoa, the parasites of human and animal cancer, since they are closely related, are suitably grouped as Cellula cancrosa specifica s. parasitaria, subspecifically muris, ratti, canis. The human form resides preferably in old diseased or physiologically inferior epithelial tissue; this explains the age incidence of cancer, and cancer in scars, fistulae, x-ray burns; on smokers' lips, on tongue and cheek from defective teeth; makes intelligible its residence in cogenital nevi and warts, in fetal misplacements which lead to stomach and pyloric cancer. Metaplasia in erosion of the portio uteri creates a locus minoris resistentiae. The breast and uterus tissues after the menopause are physiologically inferior and superfluous, hence the frequency of cancer here after loss of fertility.—*M. C. Marsh.*

10609. **KOFOID, CHARLES A., and HERBERT G. JOHNSTONE.** The oral amoeba of monkeys. *Univ. California Publ. Zool.* 33(18): 379-392. 2 pl. 1930.—Of 5 monkeys of the *Macacus cynomolgus* type (all from China), and of 34 of the *M. rhesus* type (4 from Java, 2 from Hongkong, 28 from India) examined, all of the *cynomolgus* and 21 of the *rhesus* monkeys were found infested with *Endamoeba gingivalis.* The organism, as observed in slides of gingival exudate and in cultures, is described in detail; it is indistinguishable from that of man. The intensity of the pyorrhea conditions observed roughly parallels the number and size of amoebae present. Since the animals were examined a few days after arrival, contamination by human oral amoebae is thought improbable.

10610. **KUDO, R.** Studies on Microsporidia parasitic in mosquitoes. VIII. On a microsporidian, Nosema aedis nov. spec., parasitic in a larva of Aëdes aegypti of Porto Rico. *Arch. Protistenk.* 69(1): 23-38. 2 pl. 1930.—A general review of microsporidian parasites infecting mosquitoes belonging to the genus *Aëdes.* The description of the new species includes later stages of schizogony, sporogony and spore structure.—*B. D. Reynolds.*

10611. **[KULAGIN, S. M.]** КУЛАГИН, С. М. Транзитные яица трематод в кишечнике человека. [Passage of trematode eggs through human intestines.] [French summary.] Русский Журнал Тропической Медицины [*Russ. Jour. Trop. Med., Med. & Vet. Parasitol.*] 7(2): 131-136. 1929.—With exception of 2 cases, persons in whose feces were found eggs of *Fasciola hepatica* and *Dicrocoelium lanceatum* showed no clinical symptoms of hepatic distomiasis. Repeated fecal analysis (Telemann's method) revealed that these eggs were present in the feces of individuals or whole families after eating boiled liver of infested animals. Having found prior to the experiment that his feces were free of parasites, the author ate liver containing their eggs, and during next 3 days found the eggs in the feces. In all cases the eggs preserved their original structure despite cooking and boiling.

10612. **Le ROUX.** A brief review of the literature dealing with the kidney-worm (Stephanurus dentatus Diesing, 1839) of swine, together with suggestions for its control and ultimate eradication. *Union So. Africa Dept. Agric. Pan-African Agric. and Vet. Conf. Papers Vet. Sect.* p. 112-118. 1929(1930).

10613. **LINTON, RICHARD W.** Blood changes during trypanosome septicemia. *Amer. Jour. Path.* 6(5): 627. 1930.—Abstract.

10614. **[LIŪBIMOV, M. P.]** ЛЮБИМОВ, М. П. Опыты определения времени всплывания и осаждения яиц некоторых видов кишечных паразитов в насыщенном растворе NaCl (по Fulleborn'y). [Determination of time element in surface floatation and sedimentation of some intestinal parasite eggs in saturated NaCl solution (after Fülleborn).] Русский Журнал Тропической Медицины, Медицинской и Ветеринарной Паразитологии [*Russ. Jour. Trop. Med., Med. & Vet. Parasitol.*] 7(7): 450-456. 1929.—The experiments seek to determine: (1) the minimum time necessary for the first eggs to rise to the surface of the solution; (2) the optimum (most convenient) time for the preparation of smears, when (after the minimal period of sedimentation) the maximal number of eggs can be taken from the surface; (3) the influence of the saturated NaCl solution upon the eggs. Eggs of the following were used: *Ascaris lumbricoides, Parascaris equorum, Toxascaris limbata, Toxocara mystax, Trichocephalus crenatus,* and some undetermined species of equine Strongylidae. Eggs were taken either from fresh feces or directly from the parasites. With the dilution 1:15-20, the time-minimum required for the eggs to float was 1-5 min.; at 1:7, floatation is delayed up to 10 min. With the dilution 1:15-20, and with large quantity of eggs (up to 1000), the optimum time is 5-20 min.; with smaller number of eggs (up to 200), the optimum is lowered to 5-10 min. Plasmolysis of the eggs was the only influence exerted by saturated NaCl solution. All spp. yielded the same results.

10615. **MOGAN, D. O.** The entozoal parasites of the goat in Britain. *British Goat Soc. Year Book* 1930: 32-34. 2 pl. 1930.—A study was made of 36 goats from various parts of the country. With 2 exceptions, *Skrjabinema ovis* and *Trichostrongylus capricola,* the worms found are also common parasites of sheep in this country.

10616. **MÖNNING, H. O.** Epizootology of worm infection. (With special reference to worms of domestic animals.) *Union So. Africa Dept. Agric. Pan-African Agric. & Vet. Conf. Pretoria, Papers Vet. Sect.* p. 94-101. 1929(1930).

10617. **NEVZAT, BAYTAR A.** Bir ördegin guddevi midesinde husuî evsafta bir nevi Tropidocerca. [Peculiar Tropidocerca in the gizzard of the domestic duck.] [In Turkish.] *Baytarî Mecmua. (Rev. Vét. Constantinople)* 7(2): 54-59. 1929.

10618. **NIIMI, D.** On the outbreak of black-head in Japan. [Japanese, with English abstract.] *Jour. Jap. Vet. Sci.* 9(3): 256-263. 2 pl. 1930.—According to the author's observations this disease has been occurring among chickens in summer for several years, though mistaken for coccidiosis. Many young chickens 2-3 months old have been destroyed, mortality being 50%. The observations of Th. Smith and others were confirmed in the liver and caecum of all cadavers, permitting definite diagnosis of blackhead.

10619. **[NIKOLAEV, B. P., and V. V. YAKOVLEVA.]** НИКОЛАЕВ, Б. П., и В. В. ЯКОВЛЕВА. О судьбе половых форм Pl. vivax в полости желудка комаров рода Culex, Theobaldia и Aedes. [Sexual forms of Plasmodium vivax in the abdominal cavity of Culex, Theobaldia and Aedes.] [French summary.] Русский Журнал Тропической Медицины, Медицинской и Ветеринарной Паразитологии [*Russ. Jour. Trop. Med., Med. & Vet. Parasitol.*] 7(9): 577-582. 1 fig. 1929.—*C. pipiens, T. alaskaensis,* and *Aedes salinellus,* all immune to malarial infection, were allowed to feed on the same malarial patients simultaneously with *Anopheles maculipennis.* Digestion of the asexual forms proceeded with the same rapidity as in *Anopheles,* but the sexual forms of *Plasmodium vivax* were not digested either by *Anopheles* or the other 3 species. The gametes were fecundated and formed the ookinetes, and even "mature" oocysts, as in the abdominal cavity of *Anopheles.* But whereas *A. maculipennis* showed the complete cycle of development, with the ookinetes leaving the abdominal cavity and entering the stomach wall, in *C. pipiens, T. alaskaensis,* and *A. salinellus* neither oocysts nor sporozoites were ever seen in the stomach wall, and the further destiny of the "mature" ookinetes in this case is still unknown. Since the sexual forms are not digested, the immunity of these mosquito species depends, apparently, not upon the digestive properties of their alimentary juices in respect to gametocytes, but upon the conditions of introduction of ookinetes into, and the development of oocysts in, the stomach wall.

10620. **NISHIMURA, FUKUTARO.** On the development of Gongylonema orientale Yokogawa in the final host. *Taiwan Igakki Zasshi* [*Jour. Med. Assoc. For-*

mosa] 308. 73-79. 3 pl. 1930.—Development is divided into 3 stages. The 1st parasitic or 3rd larval stage covers the period from invasion of the host (rat) until the 1st moult, 4-9 days later; structural changes in the larva are discussed. The 2nd parasitic or 4th larval stage includes the time between the 1st and 2nd moults, a period of 8-10 days, with a slightly longer time in the ♀. The organs now begin to differentiate, so that circumoral nerve ring and ganglia, cervical and cephalic glands, lateral line, the genital primordia and the external and internal reproductive organs of the ♂ and ♀ can be readily studied.—*E. C. Faust.*

10621. [OLEINIKOV, S. V.] ОЛЕЙНИКОВ, С. В. К вопросу о диагностике и эпидемиологии энтеробиоза. [Diagnosis and epidemiology of enterobiasis.] [French summary.] Русский Журнал Тропической Медицины, Медицинской и Ветеринарной Паразитологии [*Russ. Jour. Trop. Med., Med. & Vet. Parasitol.*] 7(6): 393-402. 1929.—Helminthological investigation in Ufa, involving 5130 perianal and anal grattages (Ruotsolainem's method), yielded positive results in 3399 cases. *Enterobius vermicularis* was found in 3042 cases, other parasites, e.g., *Ascaris lumbricoides, Taenia* sp., etc., being present in very few cases. The author believes that the main method of infection with *E. vermicularis* is through breathing dust containing eggs. The egg-laying process as observed by him differs considerably from that described by Wilhelmi and others.

10622. PICARD, W. K. Pluimveeziekten in Nederlandsch-Indië. [Poultry diseases in Dutch East Indies.] [With German and English summaries.] *Ned.-Indische Blad. Diergeneesk.* 43(1): 24-29. 2 fig. 1931.—On West-Java poultry-farms the author diagnosed an intensive infection with *Davainea proglottina,* starting with loss of appetite, anaemia and haemorrhagic diarrhoea; the animals die in a paralytic and cachectic state.

10623. PURVIS, G. B. Setaria labiato-papillosa (Alessandrini, 1838) or Setaria digitata (von Linstow, 1906). *Vet. Rec.* 11(19): 528-529. 4 fig. 1931.—From Malayan material from water buffalo and ox, the author concludes that the latter is a synonym of the former. The prevailing impression is that these worms are harmless, but this is not always the case, as a post-mortem examination of 1 ox showed a patch of hemorrhagic inflammation on the visceral peritoneum, which coincided with presence of 6—8 *S. labiato-papillosa.* On another occasion, *Setaria* sp. was extracted from fibrinous peritoneal exudate; on another, *S. labiato-papillosa* from the same type of lesion and, on another, calcified material of similar appearance was obtained.

10624. REGENDANZ, P. Der Zuckerverbrauch der Trypanosomen (nach Versuchen in vitro bei 37° C.) und seine Bedeutung für die Pathologie der Trypanosomeninfektionen. *Zentralbl. Bakt. Abt. I. Orig.* 118 (3/4): 175-186. 1930.—The author studied the decrease in sugar content of serum-blood mixtures containing trypanosomes and incubated at 37° C., using *T. rhodesiense, T. congolense* and *T. lewisi.* The loss of sugar in these mixtures is caused mostly by the metabolism of the trypanosomes; no loss takes place when the trypanosomes are dead or dying. The utilization of sugar by trypanosomes in vitro at 37° C. is considerable. No difference could be observed between the amounts of sugar consumed in vitro after 15 minutes incubation at 37° C. by pathogenic trypanosomes and *T. lewisi.* The author emphasizes the significance of the sugar utilization by trypanosomes for the pathology of trypanosome infections.—*R. Dubos.*

10625. [SHNEERSON, A. A.] ШНЕЕРСОН, А. А. Степень распространения Hymenolepis nana среди детского населения Одессы. [Distribution of Hymenolepis nana among the children of Odessa.] [German summary.] Одеський Медичний Журнал (*Odessaer Med. Zeitschr.*) 5(1/2): 53-64. 1930.—Out of 556 boys, 68.9% were positive for worms, 6.7% for *Hymenolepis nana.* Out of 694 girls, general infection was found in 71%, *H. nana* in 5.8%. The parasite was comparatively seldom found alone (18.2%), mostly in combination with *Trichuris trichiura* and other species. As to age, 4 to 8 years showed the greatest percentage of *H. nana* infection; starting with 8, infection decreases steadily. No infection was found under 1 yr. of age. Among children from the less sanitary districts, *H. nana* is met more frequently. Out of all children examined (1250), it was found in 6.2%; but taking into account the biological peculiarities of *H. nana* (closed uterus), and the defects of the fecal method, the real infection average must be rather higher.

10626. SILVA, FLAVIANO, e EDUARDO de ARAUJO. Leishmaniose experimental. (Nota prévia.) *Brasil-Med.* 44(36): 997-999. 1 fig. 1930.—The authors transmitted American leishmaniosis of man to a *Macacus rhesus.* An emulsion made from the material in the human lesion was injected intradermally in the nasal region of the monkey. Incubation was 81 days.—*C. Dawley.*

10627. SMIT, H. J., en R. ROTOSOEDIRO. Acuaria hamulosa (Dies.). [With German and English summaries.] *Ned.-Indische Blad. Diergeneesk.* 42(6): 607-610. 1 fig. 1930.—From the intestines of a chicken (Leghorn × indigenous) the authors report *Acuaria hamulosa* in Dutch East Indies, known heretofore only from America, Europe and Australia.

10628. SZIDAT, L., und R. WIGAND. Über Fuadinwirkung bei Bilharziella-Enten. *Arch. Schiffs- u. Tropen-Hyg.* 35(3): 159-171. 1931.—Experiments were carried on to determine the potency of this antimonyl compound on *Bilharziella polonica* Kow., a blood fluke of the subfamily Bilharziellinae. Each ♀ has a single egg in the uterus, which is laid into the portal vein and works its way through the intestinal mucosa into the feces. The miracidium, which hatches when the feces are diluted with water, invades the snail *Planorbis corneus* L., where the sporocysts and cercariae develop. The latter emerge from the snail and become attached to the feathers of ducks swimming in the water. Either via the skin route or by artificially feeding in crumbs the larvae reach the mesenteric veins and become mature in about 3 weeks. A dosage of fuadin 10 times as large as that utilized in human schistosomiasis had no effect on the infection or on the blood picture of the ducks.—*E. C. Faust.*

10629. THOMAS, J. ANDRÉ. Sur le Sporozoaire (Coccidie) parasite de Nereis diversicolor O. F. M. *Compt. Rend. Soc. Biol.* 104: 138-140. 1 pl. 1930.—A description of the principal developmental stages and of microgametogenesis of a new coccidium*, probably belonging to *Caryotropha.* [No name is proposed.]—*J. A. Thomas (transl.).*

10630. VILJOEN, P. R. The East Coast fever problem in the Union. *Union So. Africa Dept. Agric. Pan-African Agric. & Vet. Conf.* [*Pretoria*] *Papers Vet. Sect.* P. 145-157. 1929(1930).—A discussion of recent outbreaks and eradication methods.

10631. [VINOGRADOV.] ВИНОГРАДОВ. Глистные заболевания русского и самоедского населения тиманской тундры. [Helminthiasis among Russians and Samoyeds of the Timan tundra.] [French summary.] Русский Журнал Тропической Медицины, Медицинской и Ветеринарной Паразитологии [*Russ. Jour. Trop. Med., Med. & Vet. Parasitol.*] 7(5): 329-332. 1929.—From fecal examinations of 334 persons, *Diphyllobothrium latum* was found in 74% of Russians and 95-100% of Samoyeds. This high percentage is ascribed to the use of raw meat and fish. Conditions are highly insanitary. Other parasites, e.g., *Enterobius vermicularis* and *Ascaris lumbricoides,* are exceedingly rare.

10632. VOLKMAR, FRITZ. Trichomonas diversa n. sp. and its association with a disease of turkeys. *Jour. Parasitol.* 17(2): 85-89. 1 fig. 1930.—*T. diversa* occurs in the upper digestive tract of turkeys and is pathognomonic for a new disease characterized by peculiar excrescences of the esophageal mucosa. The flagellate measures 14 × 9 inches in the active stage (drop-form) and 13 × 13 inches in the resting phase. The axostyle, measuring 14-16 inches is capable of active flexibility.

The center is connected with the opposite side of the nucleus by a fibrilla. The forward flagellae number three; the axoneme is detachable.—*F. Volkmar.*

10633. **WALLACE, FRANKLIN GERHARD. Lung flukes of the genus Paragonimus in American mink.** *Jour. Amer. Vet. Med. Assoc.* 31(2): 229-234. 1931.—*Paragonimus kellicotti* is reported. Diagnosis is most easily made by fecal examination. In most cases the ova are so numerous that they are readily detected by the direct smear method. The eggs are distinctive in appearance and can be identified by the prominent operculum and the thickening of the shell at the opposite end. *P. kellicotti*, like its Asiatic congener, uses the crayfish as second intermediate host. The author succeeded in heavily infecting cats with cysts from the pericardial region of *Cambarus immunis spinirostris*. There is little chance for pen-raised animals to become infected, as they are seldom fed these crustaceans. None of the cases reported have been in animals definitely known to be pen-raised. Furthermore, subsequent examinations of 143 carcasses, nearly all young animals bred in domestication, revealed no cases of *Paragonimus*. It is suggested that mink-buyers insist on strictly pen-raised stock, and secure fecal examinations to determine possible infections.—*From author's conclusions.*

10635. **ANONYMOUS. Transmission of Leishmania donovani.** *Nature [London]* 127(3200): 308. 1931.—Lieut.-Col. Shortt announces successful transmission of *Leishmania donovani* to Chinese hamster by bites of artificially infected *Phlebotomus argentipes.*

FILTERABLE VIRUSES, BACTERIOPHAGE, ETC.

GEO. H. SMITH, *Editor*

(See also in this issue the subsection "Infectious Chloroses" in the section Phytopathology; and Entries 10330, 10331, 10343, 10429, 10438, 10451, 10465, 10486, 10508, 10524, 10559, 10659, 10677, 10693, 10699, 10709, 10723, 10937)

GENERAL

10636. **ALTERTHUM, HANS. Beiträge zur Frage des Herpes zoster varicellosus.** *Monatsschr. Kinderheilk.* 40(4): 330-343. 18 fig. 1928.—Study of the relation of herpes zoster to chickenpox, based on 36 cases of herpes zoster in the children's hospital, Berlin, during 1920-1928, showed that a majority (23) of the zoster cases either were followed by, or in turn followed, cases of chickenpox occurring within the same hospital ward. The number of cases of zoster was not always proportional to the number of cases of chickenpox, frequency of zoster cases being greater in certain yrs. 6 of 7 cases of zoster associated with treatment with arsenic or bismuth showed unquestioned connection with cases of chickenpox. Recovery from zoster associated with chickenpox does not always give immunity to chickenpox, and vice versa.—*M. L. Earle.*

10637. **BOURGUIGNON, D. C. L'alastrim est-il une forme allergique de la variole?** *Ann. Soc. Belge Méd. Tropic* 11(2): 127-130. 1931.—Since the virus is of the same nature, alastrim seems to be an atypical form of smallpox. It is possibly of an allergic nature, i.e., an attenuated form of smallpox of benign character which appears in epidemic zones in subjects which have been sensitized by a former contact with smallpox virus.

10638. **GORDON, M. H. Virus studies concerning the aetiology of psittacosis.** *Lancet* 218(5570): 1174-1177. 1930.—Passage of the parrot virus through the mouse rapidly increases its virulence. As a rule, the unfiltered virus kills more surely and quickly than the Seitz filtrate. Exposure for 30 min. to 55°C. attenuates the virus for mice. Exposure to 80 and 100° appears to inactivate the parrot virus completely. The parrot virus offers considerable resistance to desiccation and to certain disinfectants. Apparently the virus was more abundant in the spleens of mice than in their blood. The papular eruption produced by the parrot virus when injected intracutaneously into rabbits closely resembles that excited under similar circumstances by certain strains of herpes virus of human origin. Rabbits injected intracerebrally with parrot virus showed evidence of meningitis, the exudate being chiefly composed of lymphocytes and the meninges being slightly thickened at places. In 2 rabbits there was also some evidence of encephalitis. Thus far, virus from human cases has not displayed the same degree of pathogenic stability for mice as that from parrots.—*J. A. Kennedy.*

10639. **GILDEMEISTER, E., und GEORG HEUER. Über den Nachweis von Herpesvirus im Blute bei experimentell infizierten Kaninchen und über experimentellen Hautherpes. [Demonstration of herpes virus in the blood of experimentally infected rabbits, and experimental herpes.]** *Deutsche Med. Wochenschr.* 55(22): 905-907. 1 fig. 1929.

10640. **HERRMANN, OTTO. Lyssavirus im menschlichen Speichel.** *Zeitschr. Immunitätsforsch. u. Exp. Therap.* 58(3/4): 384-388. 1928.—Saliva from a boy with pronounced rabies was found infective for rabbits. This is contrary to the claim of von Salvioli and others who were unable to demonstrate the virus in human saliva. In light of the positive evidence, protective antirabic inoculation should be given to all persons bitten by rabid humans.—*R. R. Hyde.*

10641. **INO, SHIGERU. Beitrag zur Kenntnis des Antibakteriophagenserums.** *Zentralbl. Bakt. I. Abt. Orig.* 112(3/4): 252-263. 1929.—Lysis in a culture containing bacteria and bacteriophage was inhibited by antibacteriophage serum, when the serum was added to a culture not more than 24 hrs. old. The antilytic effect of serum increased with its content of antibodies. The antiserum inhibits, but does not destroy, bacteriophage. Absorption of antiserum with killed bacteria failed to influence the antilytic effect. The experiments allow no conclusion as to the genetic relationship of bacteriophage and bacterium.—*R. Koch.*

10642. **McKINLEY, EARL B. The bacteriophage.** *Porto Rico Jour. Publ. Health & Trop. Med.* 5(1): 21-32. 1929.—A review.

10643. **NOVI, IVO. Il cosidetto invecchiamento del virus rabbico di laboratorio. (Nota sperimentale.) [So-called attenuation of rabies virus in the laboratory.]** *Rend. Ses. R. Accad. Sci. Ist. Bologna Cl. Sci. Fis.* 32: 119-122. 1927-1928 (1928).—Contrary to the frequently expressed opinion that the fixed virus strain originally employed has lost its virulence, the author has seen no such degenerative change with his strain carried by serial passage since 1889. Subdural inoculation at present kills rabbits after 3 days' incubation, i.e., $\frac{1}{3}$ of the original period. When injected subcutaneously, incubation is protracted, and the period increases in subsequent subcutaneous passages, but it returns to normal after a few subdural passages. After desiccation at 20°C. over $CaCl_2$, for 6 days, the spinal cord still kills rabbits after 12 days. Since after desiccation for 3 days there is a similar period of incubation, it is considered safe in the later stages of treatment to employ cords dried for 2 days. The original strain and method of Pasteur are still effective, and it would appear dangerous to employ a fresh strain which has not entirely lost its virulence for man. —*C. Prausnitz.*

10644. **PIKKARAINEN, JORMA. Die Spezifität der Bakteriophagen, ihre Haltbarkeit und Wirkung in der Paratyphusgruppe.** *Acta Soc. Med. Fennicae "Duodecim" [Suomalaisen Lääkäriseuran Duodecim'in]* 13[Ser. A.]

(3) : 1-16. [Art. 11.] 1931.—3 races of paratyphoid bacteriophage were tested on 32 paratyphoid strains by Bergstrand's titration method. 7 of the strains yielded colonies of the G and R types. The R strains were more susceptible to lysis than were the G derivatives. All of the strains were agglutinated by 3 immune sera, the R strains more easily than the G strains.

10645. VEDDER, A. Een bacteriophaag voor erysipelas-streptococcen. [A bacteriophage for erysipelas streptococci.] *Nederlandsch Tijdschr.-Hygiëne, Microbiol. en Serol.* 6 (1) : 62-70. 3 fig. 1931.—Of strains of erysipelas streptococci, only those which yield smooth colonies are susceptible to bacteriophagy; rough-colony strains are resistant. The smooth-colony dissociants of rough, resistant strains are susceptible. Changes in resistance can be correlated with growth characteristics.—*From abstract by A. Vedder.*

LOWER ANIMALS

10646. DALLING, T. Distemper in the fitch. *Vet. Record* 11 (42) : 1051-1052. 1931.—From experimental work and a review of the literature, the following conclusions are drawn: Distemper of the fitchet, ferret, and dog is caused by the same filterable virus. Symptoms in the fitchet are similar to those in the ferret. Fitchets can be successfully immunized by injection of vaccine, followed in 10-14 days by a small dose of living distemper virus. Hyperimmune dog serum may be of some value in preventing development of distemper in the fitchet or ferret if injected soon after exposure.

10647. DRESCHER, LUDWIG. Die intraperitoneale Übertragung der Maul- und Klauenseuche auf das Meerschweinchen. *Miessner-Festschrift* p. 55-69. Publ. by Fritz Eberlein: Hannover, 1930.—A high % of guinea pigs can be infected intraperitoneally with a virus of high virulence. The minimum dosage is 0.1 cc.; 0.2 cc. was very satisfactory. If the absolute amount is diluted with a physiological saline, infection results more readily Addition of glycerin to the virus aids infection. Scarification has no effect on results of inoculation or on incubation period.—*Author's summary (transl.).*

10648. LIPSKA, IRÈNE. D'Herelle's phenomènon in milk. *Internat. Dairy Congr. Eng. Ed.* 1931 (Sect. 2) : 97-98. 1931.—A summary.

10649. MENDELSOHN, WILLIAM, C. E. CLIFTON, and M. R. LEWIS. Ultrafiltration studies on the active agent of the chicken tumor no. 1. *Amer. Jour. Hyg.* 14 (2) : 421-425. 1931.—The active principle of chicken tumor no. 1 readily passed through 0.5%, 1%, 2%, and 3% collodion membranes. In 1 case it passed the 5% membrane. Filtrates passing the 4% and 5% membranes were free from demonstrable action. The particle size of the active agent of chicken tumor no. 1 was found to be less than 50 mμ and possibly less than 15 mμ.—*Author's summary.*

10650. MEYER, K. F., C. M. HARING, and B. HOWITT. The etiology of epizootic encephalomyelitis of horses in the San Joaquin Valley, 1930. *Science* 74 (1913) : 226-227. 1931.—The infective virus has thus far been demonstrated in the central nervous system by experimental inoculations from 2 field cases. Guinea pigs were found regularly susceptible and the most suitable of any animals tested for experimental study. Not only intracerebral injections, but intranasal instillations of brain emulsions successfully transmitted the virus to guinea pigs and rabbits, but not to horses. In 1 experiment the virus in 50% glycerine at 4° C. survived for 31, but not for 105 days. It is filterable through Berkefeld V and N candles and retains its activity at dilution of 1 : 1000. Sera of spontaneously recovered or resistant horses fail to neutralize the virus, while the sera of recovered rabbits, guinea pigs and monkeys may contain antiviral substances.

10651. RUPPERT, FRITZ. Über Virulenzschwankungen des Virus der Schweinepest. *Miessner-Festschrift* p. 167-173. Fritz Eberlein: Hannover, 1930.—Great variations exist in the virulence of hog cholera virus. An immunity brought about by a weak virus can be overcome by a strong virus. The virulence variations may appear very suddenly and are to be explained by the action of bacteria or their decomposition products.—*Author's summary (transl.).*

10652. STAMO, V. Contributiuni la studiul difteroido-variolei paserilor. [Avian diphtheroid-variola.] [With French summary.] *Arch. Vet. [Bucureşti]* 23 (1/2) : 1-57. 3 fig. 1931.—The various forms of avian diphtheroid-variola may be produced experimentally by different routes of inoculation with virulent products from any of the forms. The disease is easily transmitted from fowl to fowl, and those recovering develop a solid immunity. Pigeons can not be infected with fowl pox but they are readily infected with pigeon pox virus, after which a solid immunity develops. Pigeon pox is transmissible to fowls, in most cases producing a benign form conferring immunity. Attempts to infect pigeons with sheep pox or vaccinia failed. Fowl diphtheroid-variola was transmitted by the brain or liver of affected fowls, and a phenolized vaccine prepared from these organs produced immunity but gave a large % of infections. Vaccine from brain or scabs, prepared by the Verge technique, and formolized vaccine prepared from brain, also gave unsatisfactory results. Antidiphtherin had no immunizing action. Vaccine from unmodified brain and scabs of pigeon pox immunized fowls against fowl pox virus. Injections of hexamethylenetetramine were without therapeutic effect in the 60 cases tried. Glycerine-iodine compresses, accompanied by local washing with boric acid, after removal of scabs, gave good results. —*From French summary (transl.).*

BACTERIOLOGY AND OTHER MICROBIOLOGY

MEDICAL

10653. ANDREWS, EDMUND, and LEO HRDINA. Hepatogenous cholecystitis. *Arch. Surg.* 23 (2) : 201-214. 11 fig. 1931.—In 25 dogs, biliary stasis was produced by ligation: in 12, of the cystic duct; in 5, of the common duct near the duodenum; in 6, of both the common and cystic ducts; and in 2, of the common duct, with bilateral nephrectomy. The dogs were killed 24 hrs. to 2 mos. after operation and the gall-bladder studied. In 22 of the 25, the gall-bladder was infected with characteristic hepatic anaerobes, by direct extension from the liver.

10654. ARAUJO, EDUARDO de. Diagnostico experimental de sodoco. [With English summary.] *Brasil-Med.* 45 (40) : 924-928. 1931.—Rat-bite fever was transmitted from a child to mice and guinea pigs. Blood taken from a girl about 1 yr. old, during the febrile stage, was inoculated into mice previously examined to make certain that no spirilla existed in their blood. Blood transfers were subsequently made to young guinea pigs; one of the 1st series developed signs of experimental sodoku (loss of hair and of wt.), dying about 1 mo. later. All guinea pigs inoculated in the serial passage of blood have shown in their blood organisms morphologically like *Spirillum minus* Carter.—*Author's summary.*

10655. **BARCO, PAOLO.** Granuloma del polso a sede sottocutanea da micete del genere Halobyssus Zukal. [Subcutaneous granuloma of the wrist due to a fungus of the genus Halobyssus.] *Arch. Ital. Chir.* 29(3): 257-274. 13 fig. 1931.—This fungus is referred to *Halobyssus*, of which *H. moniliformis*, found in sediments of water rich in NaCl, is the only species known. Whether the organism is a new sp., as might be inferred from its parasitic existence, has not been determined.

10656. **[BEINISOVICH, N. M.]** БЕЙНИСОВИЧ, Н. М. Ассоциация кишечных бактерий при брюшном тифе. [Association of intestinal bacteria in typhoid fever.] Журнал Микробиологии и Иммунобиологии (*Jour. Microbiol. et Immunobiol.*) 7(2): 183-188; German summary, 236. 1930.—Fecal examination of 12 patients showed 3 groups of intestinal microflora: (1) normally encountered—e.g., *B. coli commune, Streptococcus faecalis, B. lactis aerogenes;* (2) putrefactive microbes—*Sarcina flava, B. pyocyaneus, Corynebacterium flavum, C. pseudodiphthericum, Alcaligenes faecalis, Micrococcus candidus, Kurthia zopfii, Flavobacterium alcaliaromaticum, Rhodococcus roseus, B. subtilis,* and *B. mesentericus;* (3) pyogenic group—*Staphylococcus aureus* and *Staph. albus.* The putrefactive flora predominated at the beginning and end of the ulcerative process.

10657. **BENEDEK, T.** Über Schizosaccharomykose. Eine Synthese. *Se Congr. Internat. Dermatol. et Syphiligr.* Copenhague 5-9 août 1930.—This fungus [*Schizosaccharomyces hominis*] appears to be indigenous to man, being recoverable in the blood (17.48%). In the fluid from experimentally induced blisters, it was found in 66.55% of cases, independently of any kind of pathological process. The parasite is transmitted from placenta to offspring. It affects internal organs, e.g., the liver. On the skin, it produces either violent expressions (pompholyx, pityriasis rosea), or more subacute ones like seborrheic eczema.—*F. D. Weidman.*

10658. **BENEDEK, T.** Syphilis and pityriasis rosea of Gibert. *Urol. & Cutaneous Rev.* 35(4): 3. 1931.—The author amplifies the considerations of his previous work (see preceding abstract) by indicating more precisely how the organism becomes pathogenic in the direction of inducing skin lesions. Thus, in the case of *Schizosaccharomyces hominis,* indigenous to the blood stream of man, it is normally restrained from pathologic effects by the liver,—particularly by its reticulo-endothelial system. In the presence of liver disease, the reticulo-endothelial system becomes blockaded, permitting the microorganism to be arrested in the skin and the efflorescences of pityriasis rosea to become developed. In view of the notorious pathologic effects of syphilis on the liver, this explains the frequent occurrence of pityriasis rosea in syphilitic subjects.—*F. D. Weidman.*

10659. **BIANCALANA, L., et M. BOGETTI.** Sur l'étiologie de l'hydrocèle essentiel. *Soc. Internaz. Microbiol. Boll. Sez. Ital.* 3(9): 565-568. 1931.—The authors inoculated and later reinoculated through 3 passages, a total of 65 guinea pigs with fluids and filtrates from 10 definite cases of this type of hydrocele. Post-mortems have never shown the presence of lesions of the classical tuberculous type or of those due to a filterable virus. Smears have always been negative for acid-fast bacilli. These results, while not permitting the exclusion of a tuberculous pathogenesis, indicate it to be at least rather rare.—*Authors' résumé (transl.).*

10660. **BIGGER, JOSEPH W.** Brucella abortus in relation to man in Ireland. *Vet. Jour.* [*London*] 87(8): 387-392. 1931.—Of 500 sera examined, 100 showed the presence of agglutinins in a dilution of 1-20, 22 in a dilution of 1-50 and 10 at 1-125, none going higher. No clinical survey was made of the persons furnishing the blood. It is concluded that clinical undulant fever is a rare disease in Ireland.—*I. E. Newsom.*

10661. **BLUMENBERG, WALTER.** Tuberkulose und Ernährung. Physiologische Tatsachen und experimentelle Untersuchungen. *Zeitschr. Tuberk.* 59(5): 305-321. 1931.—The effect of diet (alkaline, acid, normal) was tested on 60 ♂ guinea pigs (wt. 330-390 gm.) in 3 groups of 20 each. At the end of 9 mo., increase in weight was 41.5%, 25.8%, and 48.7%, respectively. The alkali reserve (A.R.) was high in animals on alkaline diet and low in those on acid diet; no changes could be found in the hemogram. Animals in excellent general condition were next infected with 1/10,000 mg. of a human strain of tubercle bacillus of moderate virulence in a homogeneous suspension in Na oxalate, a dose which induced progressive but not abrupt infection. The primary lesion appeared in all on the 10th to 12th days, in 3 wks. there was a nodule, in 5-7 wks. a fistula, and in 8-10 wks. a defect with undermined edges. Cultures of pus showed progressive diminution of acid-fast bacilli. Swelling appeared in the inguinal glands in 12 days, was the size of a pea in 3 wks., and that of a bean in 8-10 wks. Animals on alkaline diet lived 105.6 days; on acid diet, 64.4 days; and on normal diet, 99.4 days. This quite parallels the previous relative gain in wt. Necropsy showed that lesions in animals on acid diet were no more extensive or malignant than on the others. It was thus the unfavorable diet, not the severity of infection, which caused death. Since 2 normal and 1 alkali animal died early of pneumonia not related to tuberculosis, the picture is still less favorable to acid diet. These results were tested on 60 more guinea pigs inoculated after 24 days on the test diet, so that the effect on the A.R. was established. Animals on normal diet lived 99.7 days (6 killed at 118 days); on alkaline diet, 99.5 (6 killed at 118 days); and on acid diet, 58.8 days (all died spontaneously). Diet had no effect on the form and course of tuberculosis or on the hemogram in guinea pigs; but it did affect the A.R. Acid diet appeared to lower the resistance, so that early death, not in direct relation to tuberculosis, appeared.

10662. **BORSALINO, GIUSEPPE.** Stato setticemico e lesioni renali. [Septicemic condition and renal lesions.] *Arch. Ital. Anat. e Istol. Patol.* 1(6): 945-952. 2 col. pl., 2 fig. 1930.—Injection into young rabbits of a suspension of *Streptococcus haemolyticus* produced degenerative changes in the renal tubuli and congestive and inflammatory changes in the glomeruli, showing that a single pathogenic agent may produce changes of different character and intensity in different parts of the renal parenchyma.

10663. **BROADHURST, JEAN, and LEILA L. GIVEN.** Bacteriology applied to nursing. A combined textbook and laboratory guide in microbiology. 498p. 290 fig. (2 col.). J. B. Lippincott Co.: Philadelphia, 1930. Price $3.—Bacteria and all related subjects are treated scientifically according to the needs of nurses. This textbook covers the nurse's immediate needs as an individual, and supplies the information necessary for care and protection of patients. Also, it includes sufficient additional material to aid in interpreting bacteriological principles, and to insure their intelligent application and modification. It is a general reference book of bacteriology in a broad sense. Laboratory exercises are included for each topic, emphasizing the features most applicable to nursing. Valuable chapters are included on vaccines, antisera, anaphylaxis and tests for immunity and disease, besides those treating bacteria and other topics ordinarily included in the field of bacteriology. The scheme followed is to give preliminary or foundation material in the beginning chapters. These are followed by chapters giving definite information regarding bacteria, protozoa, and other microorganisms. The 3rd part treats of the rôle of bacteria as a part of the general environment, next microorganisms as directly related to disease. Anaphylaxis and bacteriological tests comprise the closing chapters.—*Annie M. O'Donnell Brady.*

10664. **BUCHANAN, J. ARTHUR.** The occurrence of fungi in patients with malignant disease. *Arch. Dermatol. and Syphilol.* 21(5): 757-760. 1930.—Gastric contents, stools and saliva were cultured, and tests for alcohol and other products of fungus metabolism were made by the bichromate test. Saliva of 48 patients with malignant disease was positive for fungi; in only 2 cases

was it negative; this pertains both to cultures and to chemical tests. The authors make no attempt to discriminate between pathogenicity and non-pathogenicity of the organisms recovered. The urinary findings were probably most valuable, because they showed fermentative processes in stomach and intestines.—*F. D. Weidman.*

10665. **CARSON, WILLIAM J. Ascending urinary infection. An experimental study.** *Arch. Surg.* 23(1): 74-84. 5 fig. 1931.—Experimental infection of adult rabbits in the lower end of the ureter or wall of the bladder, passed upward through the perivascular lymphatics to the kidneys.

10666. **CASAGRANDI, CARMELITA. Sur la présence de basidioboles dans l'homme.** *Soc. Internaz. Microbiol. Boll. Sez. Ital.* 3(7/8): 399-400. 1931.—This fungus develops under conditions not previously demonstrated, related to those under which the mycoses develop. This is the 1st case of a human infection due to a *Basidiobolus*. While noting its resemblance to *B. lacertae*, the author calls it *B. hominis* (not described here as n. sp., however). For the 1st time a conidial form is observed in the infection caused by this fungus, and it is suggested that the fungus exists under very different forms from those previously known.

10667. **CIFERRI, RAFAELLE, and BAILEY K. ASHFORD. Two strains of Pullularia pullulans (De Bary) Berkhout isolated from the human skin.** *Porto Rico Jour. Publ. Health & Trop. Med.* 5(2): 188-195. 1 pl 1929.

10668. **CLARENBURG, A. Voedselvergiftigingen door bacterien uit de Salmonellagroep. [Food poisoning due to bacteria of the Salmonella group.]** [With German, English and French summaries.] *Tijdschr. Diergeneesk.* 58(20): 1098-1111. 1931.—The author critically reviews the work on milk and meat poisoning due to the *Salmonella* group, and emphasizes the importance, for diagnosis, of examination of feces and serum from suspected cases and per os inoculation of mice with suspected material.

10669. **CLAUBERG, K. W. Zur Praxis der bakteriologischen Typhus-Paratyphus-Diagnostik.** *Zentralbl. Bakt. I. Abt. Orig.* 114(1/2): 115-118. 1929.—Comparison of enriching with malachite-green, brilliant green and tetrathionate for typhoid-paratyphoid diagnosis showed superiority of the first. In proportion to amount of enrichment, the number of positive reactions increases. Lange's polytrope culture medium can take the place of the colored media. It simplifies cultural examinations and abbreviates the time for the test.—*P. G. Heineman*

10670. **CRUVEILHIER, A., X. LECLAINCHE, et P. RINJARD. Enquête sur les rapports que présentent, en France, la fièvre ondulante de l'homme et l'avortement épizootique des bovidés.** *Office Internat. Épizooties, Bull.* 5(2): 281-288. 1931.—From a year's study, including comparison of the amount of human infection by *Brucella abortus* with the amount and wide distribution of animal infection, it is concluded that this *Brucella* has a low pathogenicity for man in France, attacking only those with lowered defense mechanism. The sporadic appearance and benign character of the undulant fever due to this organism here are the outstanding points from the inquiry.

10671. **DIMITRIJEVIĆ-SPETH, V., und LJUBOMIR JOVANOVIĆ. Krupp- und Nichtkruppstämme als gesonderte Typen der Diphtheriebakterien und ihre ungleichen Leistungen in der Kultur und im Kranken.** *Zentralbl. Bakt. I. Abt. Orig.* 121(1/2): 64-71. 1931.—Using a broth of low nutritive value, such as Hottinger-Süssmann's digestive broth, at pH 7.8-8.2, 48 freshly isolated strains of diphtheria bacillus from 10 croupous patients gave a turbid growth; 53 colonies from 21 non-croupous, pharyngeal diphtheria patients gave a clear growth. The ability of croupous strains to cloud this alkaline broth was only transiently hindered by growth in weakly alkaline sugar broth, specific serum, or at lower temp.; never could a permanent, clear-growing strain be produced. The croupous strains penetrated agar-gel to an agar content of 1:3000, with diffuse clouding; the non-croupous remained clear in the stab. A migration occurred on the surface of agar-gel in the course of a few days, even with an agar content of 1:400.

10672. **EDWARDS, LUCY L. Notes on a case of rat bite fever occurring in Chattanooga.** *Jour. Tennessee Acad. Sci.* 2(3): 29-31. 1927.—The case was probably due to *Treponema morsus muris*. Its course is described.

10673. **ESTABROOK, BERT U., and JOHN F. NORTON. Studies on the immunology of meningococci isolated from epidemic cerebrospinal fever in Detroit.** *Papers Michigan Acad. Sci., Arts and Let.* 12: 339-346. 1929(1930).—A report is made of an outbreak of epidemic cerebrospinal fever in Detroit during 1928-1929, with a mortality rate of 70%. 60% of the cases were among children under 10 yrs. old. A Group III meningococcus was found in the majority of cases examined and in more than ½ of the contact carriers.—*R. R. Spencer.*

10674. **FINNOFF, WILLIAM C., and PHILLIPS THYGESON. Bacterium granulosis in trachoma.** *Arch. Ophthalmol.* 5(4): 527-557. 1 pl., 3 fig. 1931.—A minute gram-negative, motile rod, apparently identical with that described by Noguchi as *Bacterium granulosis*, was recovered from 5 of 13 white persons, and from 1 Japanese, with advanced trachoma. The objections raised by Lindner regarding the original Indian cases studied by Noguchi cannot be applied here, because of the presence of pannus and advanced scarring in all but 2 cases. *Bact. granulosis* was recovered also from 2 of 14 trachomatous Indian children. It is either rare or absent in non-trachomatous diseases of the conjunctiva. *Bact. granulosis* may be considered more characteristic of trachoma than the inclusion bodies of Prowazek or the initial bodies of Lindner, since it can be recovered from patients in advanced stages, at a time when inclusion bodies and initial bodies are usually absent. Failure of others to discover the organism was probably due to use of unsuitable media and failure to cultivate at the optimal temp., 30° C. The bacterium was not agglutinated by serum from a single case of trachoma. Skin tests with *Bact. granulosis* antigen have been negative, with 1 exception. Bacteria morphologically identical with *Bact. granulosis* have been seen on and in the epithelial cells in smears taken from trachomatous patients and from animals having the experimental disease. Inoculation of *Macacus rhesus* with suspensions of *Bact. granulosis* produced a granular conjunctivitis identical with that described by Noguchi and also with that resulting from injection of human trachomatous material. Contact infection occurred in 1 of 2 monkeys exposed. The bacterium was successfully recovered from 2 advanced cases in animals. Since trachoma in monkeys is not identical with that in man, it may be necessary to use human inoculations to prove or disprove conclusively the etiologic relationship of *Bact. granulosis.* —*Authors' summary.*

10675. **FONSECA, OLYMPIO da, and A. E. de ARÊA LEÃO. Chromoblastomycosis.** *Rev. Med.-Cir.* [*Brazil*] 38(6): 216-236. 3 pl. 1930.—Full English translation. Chromoblastomycosis includes chronic granulomatous dermatoses morphologically resembling tuberculosis verrucosa cutis, but produced by hyphomycetes with colonies that are black in culture. The lesions are similar in morphology to those produced by *Leishmania, Coccidioides*, and *B. tuberculosis*. A detailed account is given of the history and geographical distribution of the disease. Of the various fungus organisms claimed by different authors, the North American species is one (*Phialophora verrucosa* Thaxter 1915), and the Brazilian another (*Hormodendron pedrosoi* Brumpt 1921 = *Acrotheca* Fuckel 1869). Questionable cases are cited for the batrachian, *Leptodactylus pentadactylus*, and hints of its presence on branches of plant life and in cattle are given. An analysis is made of the synonymy, involving *Acrotheca pedrosiana, A. verrucosa* and *Trichosporium*. The original case of Medlar and Lane from the U. S. A. is

abstracted in extenso, with critique; followed by a 2nd section describing the disease and organism found in Brazil—17 cases in all.—*F. D. Weidman.*

10676. FUKUDA, TOKUSHI, und KÔ ITABASHI. Über die Hyperglykämie bei der experimentellen Infektion. *Zeitschr. Ges. Exp. Med.* 76(5/6): 756-759. 1931.—Blood counts were made at 20 min. intervals after injection of the toxin from the protein of *Bacillus coli communis* into the ear vein of 26 normal and 8 splanchnectomized rabbits. There was rise in temp. but no hyperglycemia on injection of 0.1-0.3 mgm. toxin; with 1-3 mgm. there was rise in temp. and 50-100% rise in glycemia. Hyperglycemia did not appear in the splanchnectomized animals. The author considered hyperglycemia to be a sign that the infection was moderately severe, but that the body had sufficient resistance to overcome it; in very slight and in very severe infections it did not appear. Thus the infection hyperglycemia was due to the central action of the bacterial toxin on the sugar center, rather than to a peripheral action on the suprarenals or liver.

10677. GENGOU, O. Signification des substances toxiques élaborées par les staphylocoques et conditions favorables à leur production. *Arch. Internat. Méd. Exp.* 6(2): 211-218. 1 fig. 1931.—The author briefly summarizes new work confirming a previously expressed opinion that staphylococci produce, both in vitro and in vivo, a substance capable in vitro of lysis of cells and in vivo of toxic action. This secretion is not due to degeneration, but is a result of normal activity.

10678. GUILLERY, H. Neue Giftwirkungen der Tuberkulose an der Leber, und ihre Beziehungen zu den bisher ermittelten tuberkulotoxischen Fernwirkungen. *Virchow's Arch. Path. Anat. u. Physiol.* 281(3): 801-810. 4 fig. 1931.—Implantation in the abdominal cavity in 12 guinea pigs of little sacs containing tubercle bacilli, produced tuberculosis in only 1, in which the sac had become permeable; in the other 11, tuberculoid periportal foci of granulation tissue in the liver and perivascular foci in the eye, fatty tissue, muscles and skin. Others have extracted from tubercle bacilli substances which, injected into the organism, produce similar lesions.

10679. HAASE, W. Untersuchungen operativ entfernter Gallenblasen auf ihren Keimgehalt. *Bruns' Beitr. Klin. Chir.* 152(2): 305-309. 1931.—Of 75 gallbladders removed operatively, 36% were free of germs; 32% contained *Bacillus coli;* 24%, various cocci (more than ¾ enterococci). Apparently, bacterial infection from the intestine is more frequent than from the blood stream.

10680. HARDY, MARY, and JEANNETTE CHAPMAN. Ultra-violet radiation and resistance to infection; intranasal infection with the pneumococcus and with Bacterium lepisepticum in the rabbit. *Amer. Jour. Hyg.* 13(1): 255-280. 1931.—The rabbit may be poorly adapted to experiments of this type, as its rapid rise in temp. in direct sunlight makes it probable that the animal never receives any considerable amount of ultra-violet radiation under normal circumstances. Radiation was given several times a wk. for many wks. before inoculation (dose from a suberythemal level to a heavy dose causing a severe burn). Average results of 5 experiments with radiation from a mercury arc and intranasal inoculation with pneumococcus type I, showed no difference in attack or mortality rates between irradiated and control groups. Leukocytic reactions of irradiated and control groups among animals escaping infection, showed no definite differences. Irradiated animals contracting the disease showed a slightly higher and more rapid leukocytosis than did infected controls, with a less marked decrease in lymphocytes. The average of 3 experiments with exposure to direct sun or north sky light through vitaglass showed that both % of infection and mortality rate after inoculation with pneumococcus type I, were higher in irradiated animals than in a control group kept inside. Similar experiments with mercury arc radiation and infection with *B. lepisepticum* showed that radiation had no effect on susceptibility to infection, although mortality rate was somewhat lower in the irradiated group. Variation in amount of ultra-violet, from a marginal erythema to a heavy but subulcerating dose, had no correlation with resistance to respiratory infections used. In the pneumococcus infection experiments, the average complement-fixation titer for irradiated rabbits was slightly higher than for controls; but in the *B. lepisepticum* experiments, the average titer for the 2 groups was the same. There was no relation between titer and amount of radiation given. In rabbits immunized with killed pneumococci, radiation failed to accelerate antibody production or to increase the amount above normal.—*From authors' summary and conclusions.*

10681. HERRMANN, OTTO. Bakteriologische Blutuntersuchungen bei Endocarditis lenta und anderen septischen Krankheiten. *Zentralbl. Bakt. I. Abt. Orig.* 120 (7/8): 399-402. 1931.—Blood cultures were made on 33 cases with septic symptoms. 7 had characteristic symptoms of endocarditis lenta. From one of these, *Streptococcus viridans* was recovered; from 2, pneumococci. From the other cases a non-hemolytic streptococcus was found in 1 case; meningococci, in 2. The author urges that blood cultures be made repeatedly in all cases with septic symptoms, and that various culture media be used.—*E. C. L. Miller.*

10682. HESSE. Zur Bakteriologie der chronischen Mittelohreiterung. *Zeitschr. Hals-, Nasen- u. Ohrenheilk.* 29(2/5): 360-368. 1931.—In 159 cases of chronic otitis media, a mixed infection was generally found; staphylococci, *Proteus vulgaris,* diplo-streptococci and pseudo or avirulent diphtheria bacilli occurred frequently. In complicated cases, especially acute acerbations, diplostreptococci were especially frequent. *Proteus* was demonstrable in 44% of intracranial complications (50% of sinus thromboses).

10683. HOFFMANN, HEINRICH. Über Differenzen von Trichophytonpilzen aus Haut und Lymphdrüse. *Arch. Dermatol. u. Syph.* 155(Kongressber.): 212-224. 8 fig. 1928.—From attempts on 6 patients, the author isolated *Trichophyton gypseum* once from the glands regional to fungus infection of the skin. The original lesion was a suppurative ringworm of the scalp; there were no distant cutaneous metastases, such as are known as trichophytids, nor were they elicited by application of x-rays or by injection of trichophytin. No fungus was demonstrable in direct preparations. Cultures from scalp and lymph nodes were morphologically the same, but on guinea pigs the lesions induced by the scalp strain were much more extensive and virulent than those from the lymph nodes. Even after passage on guinea pig skins (3 series of animals) it was still possible to detect this difference in virulence; in the 4th and 5th series, virulence of the 2 strains became approximately equal. The author maintained the strain for 9 mo. on maltose agar, and on repeating the test, including passage through the 5 series of animals, found that the differences in virulence were still maintained. It did not hold good, however, further than the 1st passage animal; in the 2nd, 3rd and 4th passage animals the highly virulent strain from the skin became reduced to the same level of virulence as the strain from the lymph nodes.—*F. D. Weidman.*

10684. JADASSOHN, J. Lepra. [In: **W. KOLLE, und A. v. WASSERMANN. Handbuch der pathogenen Mikroorganismen. 3. Aufl. W. KOLLE, R. KRAUS, und P. UHLENHUTH** Bd. 5, Teil 2, Lief. 25.] P. 1063-1232. 4 col. pl. Gustav Fischer: Jena; Urban & Schwarzenberg: Berlin u. Wien, 1928.—With a 16½ page bibliography.

10685. JADASSOHN, WERNER. Versuche über Pilzzüchtung auf Organen. *Arch. Dermatol. u. Syphilis* 155 (Kongressber.): 203-207. 7 fig. (1 col.) 1928.—The author approaches the problem of variation and peculiarity in susceptibility of tissues to infection; it is only circumlocution to dismiss the impasse with "either the fungi are not pathogenic for internal organs or the internal organs are not receptive for the fungus infection." He points out that there are many analogies between fungus disease and tuberculosis, and intimates that findings in regard to

fungus disease could be made to apply in principle to the more important one, tuberculosis. He began with the hypothesis that certain definite substances must be present in the economy if the fungus is to endure; and seizes upon keratin as the necessary substance for such fungi as *Achorion quinckeanum*, *Microsporon audouini* and *Trichophyton gypseum*, which are practically confined in their parasitism to the skin. He tested the hypothesis by determining their growth in vitro as follows: (1) Skin (sterilized human and sterilized guinea pig skin; aseptic, unheated guinea pig fetus). (2) Internal organs (aseptic guinea pig liver, muscle, kidney, spleen). All organisms tested grew well on both groups of materials; therefore the exclusive involvement of the skin in certain mycoses is not referable to keratin content. He concludes that the fact that certain organs and species of animals are shunned by certain mycoses can be explained in vivo on the basis of some restraining influence. Such restraint may depend either on a restraining substance which disappears as such after death, or upon some mechanism of living cells. A 2nd possible explanation is to assume that some fungus-promoting substance is lacking in vivo, which, on the other hand, develops post-mortem as the result of chemical alterations. —*F. D. Weidman.*

10686. **JONES, JACK W., and HERBERT S. ALDEN. Maduromycotic mycetome (madura foot). Report of a case occurring in an American negro.** *Jour. Amer. Med. Assoc.* 96(4): 256-260. 8 fig. 1931.—A short history of madura foot is given, followed by the case report,—a negro who had always lived in Alabama, and who gave the usual history of going barefoot and being traumatized with thorns and splinters. The disease was 15 yrs. in duration. After amputation, tissues were examined histologically and cultures of *Scedosporium sclerotiale* obtained. A detailed mycological report is given, including the finding of ascus-like structures which appear to be new for this organism. Animal inoculation resulted negatively. It appears that this was the 2nd report of this organism as a cause of human disease.—*F. D. Weidman.*

10687. **JONTOFSOHN, KURT. Versuche zur Züchtung von Tuberkelbazillen aus dem Blute bei Tuberkulösen.** *Zeitschr. Tuberk.* 61(1): 35-41. 1931.—Löwenstein blood cultures were made in 41 cases of pulmonary and in 9 of surgical tuberculosis; an atypical growth of tubercle bacilli appeared in only 3. Even in severe cases, apparently only a few bacilli circulate in the blood, and those perhaps are attenuated.

10688. **KESTEN, BEATRICE M. Observations on skin diseases in Porto Rico.** *Porto Rico Jour. Publ. Health & Trop. Med.* 5(2): 185-187. 1929.—560 cases are classified as to kind and as to nature of causal agents. Exclusive of banal pigment anomalies, 51% were of fungous etiology.

10689. **[KHINCHUK, A. G.] ХИНЧУК, А. Г. Bacillus prodigiosus, выделенный при пиэлите. (B. prodigiosus isolated in pyelitis.)** Вестник Микробиологии, Эпидемиологии и Паразитологии (*Rev. Microbiol., Épidémiol. et Parasitol.*) 9(1): 112-113; English summary, 137. 1930.—From urine of a 3-yr.-old child with pyelitis, bacteria were isolated, which by morphological, cultural, serological and biochemical properties were typical *B. prodigiosus*. Emulsions from live or heat-killed cultures, in various concentrations, injected ventricularly into guinea pigs, gave negative results. Injection of 2 cc. of this emulsion intraperitoneally, and also of 0.2 cc. intraepidermally, caused at the point of injection slight hardening which rapidly disappeared. Post mortems revealed no changes in internal organs; smears were sterile.—*G. A. Lebedeff.*

10690. **KLIENEBERGER, E. Influenzabazillen bei Gesunden nach einer Epidemie.** *Zentralbl. Bakt. I. Abt. Orig.* 121(1/2): 72-75. 1931.—Throat smears (365) from 107 healthy children and 100 healthy adults during the first 7 mo. following a mild influenza epidemic, gave 131 positive smears from children and 81 from adults; of these positives, 97 and 31, respectively, were indol-positive. Hemolytic pseudoinfluenza bacilli were found in 7 children and in 18 adults. During the following 12 mo., 257 smears were made from 81 children and 176 adults; 61 and 51, respectively, were positive and of these, 37 and 22 were indol-positive; 1 child and 27 adults showed hemolytic pseudoinfluenza bacilli. The bacilli persisted for 1 mo. in 2 persons experimentally inoculated; they could not be cultivated in the cat's pharynx, showing that these are not ordinary saprophytes but are commensal in the human pharynx. The author concludes that no significance, medical or theoretical, can be attached to the presence of influenza bacilli in the nasopharyngeal space.

10691. **KOMIS, ALEXANDER. Über die Möglichkeit, den abgeschwächten Bazillus Calmette-Guérin durch Gärung in einen pathogenen umzuwandeln.** *Zeitschr. Tuberk.* 61(6): 419-422. 1931.—A 21-day culture (0.2 cgm.) of BCG was added to 10 gm. of normal serum and 10 gm. of Hansen's fluid no. 2, and 3 drops of wine yeast were added; the mixture was kept for 16 days at 38°, and for 29 days at room temp., when the bacilli and yeast had formed a precipitate. Animal inoculation (2 passages) showed that the culture had become pathogenic.

10692. **[KOROBKOVA, E. I., and S. V. MITIN.] КОРОБКОВА, Е. И., и С. В. МИТИН. К вопросу об экспериментальной скарлатине у животных. [Experimental scarlatina in animals.]** [French summary.] Вестник Микробиологии, Эпидемиологии и Паразитологии (*Rev. Microbiol., Épidémiol. et Parasitol.*) 7(1): 45-56. 1928.—Experiments were made on 35 rabbits and 5 dogs. Hemolytic streptococci or pharyngeal mucus and its filtrates from the throat of a scarlatina patient were injected into the eyes, larynx, and pharynx after preliminary sensitization of these organs with ox bile. All the dogs and 23 of the rabbits died; 3 rabbits resisted infection. Scarlatinous symptoms were present only partially: temp., angina, adenitis, rarely exanthema and polynucleosis. Symptoms were the same, whatever the infectious material used. Streptococci were found in vivo at the point of infection in 100%.

10693. **KUCZYNSKI, MAX H. Magenveränderungen durch eine Sekundärinfektion mit B. enteritidis Gärtner bei gelbfieberinfizierten Meerschweinchen.** *Virchow's Arch. Path. Anat. u. Physiol.* 281(2): 422-429. 8 fig. 1931.—In guinea pigs infected with yellow fever a secondary infection with *B. enteritidis* Gärtner produced severe gastric inflammation unlike anything produced by yellow fever infection, but essentially resembling symptoms occasionally seen in the corresponding human paratyphoid infection.

10694. **LEHMANN, JOACHIM. Experimentelle Untersuchungen an der Ratte zur Frage der Entstehung der männlichen Genitaltuberkulose.** *Bruns' Beitr. Klin. Chir.* 152(1): 139-156. 8 fig. 1931.—A suspension of tubercle bacilli was injected into the left ventricle of the heart in 7 anesthetized ♂ rats; the animals were killed 5 hrs. to 12 days later, and 140 sections made of the genitalia of each. In 2, bacilli were found in the left seminal vesicle and left epididymis on the 5th day and in the prostate on the 6th, some in the lumen of the canaliculi, some beneath the epithelial lining of the lumina, some in the interstitial tissue beside very fine capillaries. Tubercles were found in the left seminal vesicle on the 9th and 10th days, and in the lungs and kidneys after 5 days. Tubercle bacilli circulating in the blood can thus invade the interstitial tissue.

10695. **LONG, ESMOND R., and ARTHUR J. VORWALD. An attempt to influence the growth of the tubercle bacillus in the animal body by modifying the concentration of a growth-promoting substance (glycerol) in the tissues.** *Amer. Rev. Tuberc.* 22(6): 636-654. 1930.—Glycerol, fed or injected over long periods of time into 14 tuberculous rats, appeared to enhance the growth of tubercle bacilli in lesions, and to increase the extent of the disease, reproducing to some extent in vivo the conditions of growth in vitro. In an attempt to produce the opposite effect (reduction of amount of free

glycerol in tissues available for bacillary growth), palmitic acid was administered in the largest amounts tolerated, on the theory that excess fatty acid would force a synthesis of some of the free glycerol present with the fatty acid administered, to form neutral fat, which does not support growth of tubercle bacilli. Results were not perfectly consistent, but in the majority of cases in 3 series of tuberculous guinea pigs, the extent of tuberculosis was less in 24 animals treated with palmitic acid than in 11 untreated controls. Fatty acid in the amounts fed was deleterious to the general health of the animals. The number of visible acid-fast bacilli increased in the palmitic-acid animals, in spite of a decrease in the extent of the tuberculosis.—*From authors' summary & conclusions.*

10696. **LUMIÈRE, AUGUSTE. Tuberculose: Contagion, hérédité.** 301p. 23 fig. Léon Sézanne: Lyon, 1930. Price 25 fr.—The main object of this book, as stated, is to counteract the effect of dogmatism. The author outlines the history of medical opinion, from Hippocrates to the present day, concerning contagion and heredity in tuberculosis. He gives numerous statistics and quotes extensively from recent and near-recent authors (mostly French). He holds that the discovery of the tubercle bacillus and the experimental production of the disease in laboratory animals, with a dosage relatively much more massive than occurs naturally in human contacts, have obscured the importance of congenital infection and of hereditary and acquired predisposition. Medical dogmatism has accepted the laboratory demonstrations and has denied equally important clinical facts. Most human tuberculosis, in his opinion, results from infection in utero, or from post-natal infection imposed upon inherited susceptibility. The relative infrequency of frank congenital disease is explained by the idea that in many cases the strongly resistant embryonic tissues convert the usual type of acid-fast bacillus into a non-acid-fast form or into ultramicroscopical forms of relatively low virulence. These escape detection and lie latent perhaps for years, but finally may revert to the acid-fast, disease-producing type. When the fetal tissues do not produce this change, death occurs early in infancy; but the majority of children of tuberculous parents escape active disease during infancy and childhood, only to develop it in late adolescence or early adult life, when their latent bacilli regain virulence at some time of lowered resistance. Much emphasis is laid upon alcohol as a cause of lowered resistance; to this is attributed the fact that in France tuberculosis is so much more common in men than in women.—*J. B. Bullitt.*

10697. **LUSENA, MARCELLO. Splenomegalie con micosi.** (Splenomegaly with mycosis.) *Riforma Med.* 44(48): 1549-1560. 4 fig. 1928.—From a study of 2 cases of thrombophlebitic splenomegaly it is concluded that the numerous nodules of Gamna are mycelial in nature. The nodule represents the result of a localization of virus capable of affecting the entire spleen, principally aided by circulatory changes.—*F. Garofalo (transl. by G. H. Robinson).*

10699. **MORALES-OTERO, PABLO, and E. B. McKINLEY. Experimental measles in monkeys (Macacus rhesus).** *Porto Rico Jour. Publ. Health & Trop. Med.* 5(1): 36-39. 1929.—6 cases of measles in the 1st and 2nd day of eruption were cultured for the non-hemolytic streptococcus reported in measles cases by others. It was not found. Monkeys injected intraperitoneally with 5 cc. of citrated blood from 5 of these cases developed a measles-like rash 14-17 days later. Coincident with, and shortly preceding appearance of, the rash, there was a rise of 1-2° C. in temp. Cultures of blood of monkeys during the first 3 days of eruption were negative for the streptococcus and other bacteria. 2 monkeys (controls) injected intraperitoneally with 5 cc. of normal citrated human blood failed to develop rash. Blood cultures from these animals were also negative. Citrated blood from measles cases was injected intraperitoneally into 2 of the monkeys which had previously received measles blood and had developed rash. Both were immune to the 2nd injection of measles blood. Results are interpreted as direct evidence against the streptococcus etiology of measles.

10700. **MORALES-OTERO, PABLO. Experimental infection of Brucella abortus in man. Preliminary report.** *Porto Rico Jour. Publ. Health & Trop. Med.* 5(2): 144-157. 1929.—5 normal persons were fed different strains of *Brucella melitensis abortus* in pasteurized milk and closely observed. Only 1 case developed symptoms and signs resembling undulant fever, and this case was fed 2 cultures of *B. melitensis abortus* porcine strain. The experiment was repeated in 2 more cases by feeding repeated cultures of a bovine and a porcine strain, until the organism could be isolated from the feces. Only 1 case developed symptoms resembling undulant fever, viz., the case fed the porcine strain. Blood cultures of both cases developing the disease were positive, one on the 5th and the other on the 7th day of the disease. All other cases had negative blood cultures. Agglutination reactions were negative in all cases except in 1 which agglutinated 1:100 after 17 days of intermittent fever. The author believes it has been possible to produce a disease similar to undulant fever by feeding cultures of *B. melitensis abortus* (porcine). Failure to produce a similar condition with bovine strains is evidence against the bovine variety being the etiological factor in undulant fever, but this evidence should not meanwhile be considered conclusive.—*Author's summary & conclusion.*

Ges.* 44 (42): 943-944. 1929.—Communication is effected through the discharges from cows which have aborted. The disease may be communicated by contact, through food, or the bull may be responsible. It was believed until recently that man was not susceptible. In a study of 25 cases, it was determined that 6 were caused by direct contact, while 19 were caused by consumption of infected milk. The subject requires considerable additional observation.—*P. G. Heineman.*

10702. **NASTASE, GH. Impetigo contagiosa Tilbury-Fox, cu manifestari bucale.** [Impetigo contagiosa with buccal manifestations.] *Rev. Med.-Chirurg. Iasi [Roumania]* 38(2): 138-141. 1927.

10703. **NEGRONI, PABLO. Datos estadísticos sobre 157 casos de micosis estudiados en Buenos Aires.** [Statistics on 157 cases of mycosis in Buenos Aires.] *Rev. Soc. Argentina Biol.* 7(3/4): 275-282. 1931.—Most cases were produced by dermatophytes of the following genera: *Tricophyton, Microsporum, Epidermophyton* and *Achorion.* Besides the 8 cases of actinomycosis, 5 cases of blastomycosis, 4 of tinia versicolor due to *Malassezia furfur,* and a few others were observed.—*J. T. Lewis.*

10704. **NICHOLLS, EDITH E., and WENDELL J. STAINSBY. Streptococcal agglutinins in chronic infectious arthritis.** *Jour. Clin. Investigation* 10(2): 323-335. 1931.—Of sera from 110 cases of chronic infectious arthritis, 103 gave a strong specific agglutination with "typical strains" of streptococci recoverable from blood and joints of patients with this disease. Of 218 controls, some gave no agglutination; others, weakly positive. Chronic infectious arthritis can be differentiated from degenerative arthritis and from chronic polyarthritis following rheumatic fever, by the agglutination reaction. The agglutination reactions suggest different etiologies for the 3 forms of arthritis. A close antigenic relationship between "typical strain" streptococci and the hemolytic streptococci from scarlatina and erysipelas is established.

10705. **NICHOLLS, EDITH E., and WENDELL J. STAINSBY. Streptococcal agglutinins in rheumatic fever.** *Jour. Clin. Investigation* 10(2): 337-344. 1931.—

Streptococcal agglutinins were demonstrated in 46 of 59 sera from rheumatic fever patients, sustaining the theory that streptococci of the non-hemolytic type are important etiologic agents in rheumatic fever. Chronic progressive polyarthritis following rheumatic fever, although presenting a clinical picture similar to primary chronic infectious arthritis, gives evidence by agglutination reactions of being etiologically different. Further evidence is presented of the etiologic relationship between rheumatic fever and subacute bacterial endocarditis.

10706. [OSIPOVA, Z. A., and A. F. UKHIN.] ОСИПОВА, З. А., и А. Ф. УХИН. К вопросу об экспериментальной гонорее. [Experimental gonorrhea.] Вестник Микробиологии и Эпидемиологии (*Rev. Microbiol. et Épidémiol.*) 6(1): 86-89; English summary, 133. 1927.—Experiments were conducted on 11 rabbits and 1 cat infected with gonococci direct from human patients or with passage strains. The clinical picture of specific urethritis developed by rabbits, differed from human urethritis; it was short, and there was no profuse discharge from the urethra or acute inflammation of the mucosa. Examination revealed an acute inflammatory process, partly diffuse, partly limited to spread in the epithelial layer and in the subepithelial connective tissue. The urethral mucosa contained diplococci morphologically similar to gonococci.

10707. PERONI, ACHILLE. Considérations sur l'étiologie de l'ozène. (L'ozène est-il une maladie infectieuse?) *Arch. Internat. Laryngol. Otol.-Rhinol. et Broncho-Oesoph.* 9(8): 940-950. 1930.—In 27 cases of ozena examined, the author only once found the Perez-Hofer bacillus, sometimes regarded as the causal organism. In all cases the Abel-Loewenberg bacillus was found, but it is also frequently found in other conditions, including simple rhinitis. He believes that ozena is a constitutional disease and the bacillus a saprophyte.

10708. PHOTINOS, PANAGIOTIS B. Experimentelle Untersuchungen über die syphilitische Lymphdrüsenerkrankung von Affen. *Dermatol. Zeitschr.* 61(1/2): 27-30. 1 fig. 1931.—A monkey (*Cercocebus*) was inoculated subscrotally with material from a rabbit chancre and from secondary genital papules of a human patient; 22 hrs. later the inguinal glands were extirpated and implanted subscrotally into both testes of a rabbit. In a few days there was a local reaction; after 8 wks., 2 primary lesions. These were extirpated and examined in dark field, and numerous living *Spirochaeta pallida* found, which were then transferred to another monkey (results to be reported later). Various serological tests, particularly Meinicke's clearing- and micro-reactions, were made during the incubation period; *Cercocebus* became gradually positive; a positive reaction was obtained in 2 other monkeys which had been inoculated months before and had shown no signs of infection. From another monkey with rabbit chancre implanted subscrotally, the inguinal glands were transferred to the testis of a rabbit after 5 hrs.; after 40 days, syphilitic orchitis appeared and *S. pallida* was present.

10709. PINKERTON, HENRY, and KENNETH F. MAXCY. Pathological study of a case of endemic typhus in Virginia with demonstration of rickettsia. *Amer. Jour. Path.* 7(2): 95-104. 2 pl. 1931.—Study of a fatal case of endemic typhus in Virginia established the complete pathological identity of the disease with European typhus. Characteristic brain lesions were fully as numerous as in the average European case, and many of them were unusually acute. Involvement of the tunica vaginalis and scrotum was no more marked than in European typhus. *Rickettsia prowazeki* was easily and clearly demonstrated in the endothelial cells of the vascular lesions in the brain, but was not found in macrophages or neuroglial cells. A technique is described for demonstration of rickettsias in formalin-fixed brain. Demonstration of *R. prowazeki* in this material is to be added to the already overwhelming evidence in favor of its etiological relationship to typhus.—*Authors' summary*

10710 [PLEVAKO, E.]. ПЛЕВАКО, Е. Monilia как возбудитель onychomycosis и paronychia. [Monilia as cause of onychomycosis and paronychia.] Журнал Микробиологии и Иммунобиологии (*Jour. Microbiol. et Immunobiol.*) 7(2): 230-232; German summary, 239-240. 1 pl. 1930.—Observations on 7 patients showed *Monilia pinoyi* in all cultures. 7 strains were obtained and the virulence of each was tested on 3 rabbits—intravenously in large and small doses, and subcutaneously. Rabbits of the 1st series (0.3 cc.) died in 4-5 days of acute septicemia, with typical granulomatosis of liver and kidneys; *M. pinoyi* could be cultivated from all organs. In the 2nd series (0.03 cc.), the rabbits died in 21-35 days. Subcutaneous injection (3rd series) always resulted in local infiltration only. Autovaccination of patients gave favorable results.

10711. POMALES, AMÉRICO. Bacteriologic study of normal throats, pathological throats and tonsils removed at operation in Porto Rico. A preliminary report. *Porto Rico Jour. Publ. Health & Trop. Med.* 5(2): 196-210. 1929.—The bacteriological findings in 100 normal throats, 75 pathological throats and 65 pairs of excised tonsils are reported. Gram-negative cocci and non-hemolytic streptococci constituted the normal basic throat flora from Feb. to May. *Staphylococcus aureus* and Gram-positive cocci were common transients. Pneumococci were only occasionally encountered. Hemolytic streptococci were isolated from 26% of the normal throats, but true β hemolytic streptococci were isolated but once. Both hemolytic streptococci and hemolytic *Staphylococcus aureus* were limited to the region of the tonsils in most cases. Hemolytic *Staph. aureus* was isolated from pathological throats (tonsillitis) in 14 of 50 examined. Hemolytic streptococci were cultured in 32%; in 14% they were of the β type. Hemolytic *Staph. aureus* was the predominating organism in the crypts and the interior in a series of 65 pairs of tonsils examined. β hemolytic streptococci ranked 2nd. Simple swabbing of the surface of the tonsils, even if carefully done, is not a very reliable index of the organism predominating in the crypts.—*Author's summary and conclusions.*

10712. ROSENTHAL, L., and VERA B. DOLGOPOL. The lysis of tubercle bacilli in sputum. *Amer. Rev. Tuberc.* 24(3): 351-362. 1931.—A certain degree of lysis occurred in 40 sputa (from 36 patients) kept at room temp. 10-15 days. An initial increase in number of bacilli, followed by evident lysis in 10 days, occurred in 20 sputa kept at 37° C. for 15 days; in a few cases the bacilli finally disappeared completely. Of 205 sputa (from 102 patients) kept at 48° C., 141 showed signs of disintegration (apparently after 5-7 days); sputa of 26 patients kept at 60° C. underwent disintegration. These temp. proved best for lysis; higher temp. were less destructive. The concomitant flora of the sputum does not affect the staining ability of the tubercle bacilli. The lytic agent is probably the product of autolysis of the leukocytes.

10713. RUSSKICH, W. N., und E. S. KRYLOWA. Über einen Fall von primärer Gehirnaktinomykose. [A case of primary cerebral actinomycosis.] *Virchow's Arch. Path. Anat. u. Physiol.* 281(3): 797-800. 1931.

10714. SCHEUNEMANN, KARL. Untersuchungen über das Vorkommen von Tetanusbazillen im Stuhl nicht tetanuskranker Menschen. *Arch. Hyg. u. Bakt.* 105 (5): 287-299. 1931.—Microscopic, cultural, and animal inoculation studies of stools of 50 non-tetanus patients revealed no tetanus bacilli and tetanus-like rods in only 4. The human intestine is apparently a less favorable habitat for tetanus bacilli than the animal intestine.

10715. SCHULTZ, CARL. Über den Nachweis von Tuberkelbakterien im Lungenschleim. *Deutsche Tierärztl. Wochenschr.* 39(35): 545-547. 1931.—Enrichment of tubercle bacilli in bronchial sputum with 1:500 $K_2Cr_2O_7$ solution or distilled water is as good as with glycerin. Bichromate solution has an advantage over glycerin and distilled water in that the accompanying bacteria are suppressed within 24 hrs. and guinea pigs can be inoculated with the preparations without other preliminary

measures. The viability of the bacteria is not impaired by the bichromate. H_2SO_4 (5 and 10%) can not be used to kill the accompanying bacteria, since tubercle bacilli are also injured.—*Author's summary (transl.)*.

10717. **SETTI, CARLO.** Discomycosi di Rivolta (actinomycosi di Harz). (Studio storico, morfologico, fisiologico.) *Gior. Batteriol. e Immunol.* 4(7): (1-96). 48 fig. 1929.—The author reviews and presents in a systematic way the contributions, including his own, on the morphological and physiological characteristics of Rivolta's discomycosis (actinomycosis of Harz).—*N. Colosi.*

10718. **SMALL, JAMES CRAIG.** The rôle of streptococci in the rheumatic diseases. *Jour. Lab. & Clin. Med.* 14(12): 1144-1156. 1 fig. 1929.—The author reviews the recent literature on rheumatic fever. He then reiterates his belief that *Streptococcus cardioarthritidis* is the specific cause in children, and that the "destructive" and "proliferative" lesions so important in producing the cardiac damage are caused by the toxin of this streptococcus. He advances the hypothesis that the later "exudative" joint lesions are not entirely specific but represent a hypersensitization to the proteins of various concomitant streptococci. Chronic arthritis is presented as an allergic disease, the hypersensitive state of the patient being due to a protein allergen contained in streptococci without regard to a particular type. In the treatment of rheumatic fever, he gives antitoxic serum against *Strep. cardioarthritidis* during the initial, acute, toxic stage and later he treats the cases by desensitization during the "exudative" phase. For desensitization, extremely minute doses of streptococcal filtrates are given, amounting for the first dose to only 1/20th part of the exudate from a single streptococcus, or 1/20 cc. of a 1:100 million dilution of the filtrate. The treatment of chronic arthritis is concerned largely with the elimination of foci harboring streptococci, and with adequate desensitization. Stock extracts of streptococci may be employed in this desensitization, and because their dosage requirements may be the better determined through extensive clinical application, they are preferable to autogenous preparations.—*D. Thomson.*

10719. **SMITH, E. C.** Cultivation of the spirochaetes associated with tropical ulcer. *Proc. Roy. Soc. Med.* 24(2): 217-221. 1931.—Spirochaetes from cases of tropical ulcer were cultured in a modified Wenyon medium, and have now been successfully passed through 32 subcultures. A pure culture has not yet been obtained. In 5 inoculation experiments described, it is shown that the spirochaetes and fusiform bacilli, in mixed culture, are capable of proliferation and of producing ulcerated lesions in natives.—*Author's summary.*

10720. **STREMPEL, RUDOLF.** Frühzeitiger Spirochätennachweis in skrotalen Impfherden von Kaninchen nach Einimpfung von Poplitealdrüsen latent syphilitischer Kaninchen. *Dermatol. Zeitschr.* 61(1/2): 1-6. 1 fig. 1931.—In a preliminary report, the author states that 12 days after inplantation of popliteal glands of rabbits with latent syphilis into the scrotum of rabbits, it was possible to find normal spirochaetes in the surrounding tissue, though the transfer itself was free. Only after 35 days were the forms and variations described by Levaditi found.

10721. **TAKIGAWA, K.** Ueber Sycosis lupoïdes Brocq. [In Japanese, with German summary.] *Acta Dermatol.* 17(4): 245-290. 14 fig. 1931.—In 8 cases of sycosis lupoïdes Brocq. (ulerythema sycosiforme Unna), the author was able to cultivate *Staphylococcus pyogenes* (*albus* in 1 case and *aureus* in the other 7), which produced sycosis lupoïdes in biologic experiment. The vegetative nervous system of the patients showed more or less marked abnormal excitability. There was a partial disturbance of sugar metabolism. Blood picture, sedimentation rate of erythrocytes and roentgenogram of the sella turcica showed nothing noteworthy. S. Chikano's adrenaloid substance showed some increase over that in normal blood.—*From author's summary.*

10722. **TAYLOR, J., and AMAR NATH GOYLE.** Leptospirosis in the Andamans (with an appendix on the present knowledge of leptospiral infections). *Indian Med. Res. Mem.* 20. 1-190. 2 pl., 3 maps (1 col.), 1931.—In the Andaman Islands (India), one of the authors (A. N. G.) studied 64 cases of jaundice, the leptospiral nature of which was confirmed by blood culture and other methods. A detailed account of the clinical and laboratory findings is given. The cases varied in severity from the mildest non-icteric type to severe fatal cases showing all characteristics of Weil's disease. Mortality was 18.7%. Blood culture in serum-water-agar medium (rabbit serum 1 cc., distilled water 7 cc., agar 0.5 cc.) proved to be the most reliable method of laboratory diagnosis, if carried out between the 3rd and 6th days of illness. Leptospiras were found in the urine from the 12th day onwards, in 1 case up to the 44th day. Serological diagnosis was often obtainable after the 15th day; inoculation of guinea pigs with blood or urine was of little assistance. Leptospiras were seldom found in the organs of fatal cases, either by dark field examination of emulsions or in stained sections. There is usually in the early stages a definite leucocytosis with relative increase in number of polymorphonuclears. Leptospiras isolated from cases belonged to 2 serological groups. Of 28 strains studied, 24 were serologically identical and non-agglutinable by antisera prepared against a series of strains of known type, obtained from different parts of the world; this group is designated "Andamans A." These 24 strains were isolated from cases of varying degrees of severity, including fatal hemorrhagic cases. The remaining 4 strains were agglutinated by antisera prepared against cultures of the Akiyami A group, and in addition showed a specific agglutination with their own antiserum. Cultures of the Andamans A group were of low pathogenicity fo[r] adult guinea pigs. Young guinea pigs of ± 100 gm. wt. could be infected by intraperitoneal doses of 3 cc. of a rich culture. Virulence for guinea pigs was increased by sub-passages using liver emulsions, and adults could then be infected. The Andamans strains related to Akiyami A group were found non-pathogenic for young guinea pigs. Epidemic jaundice in the Andamans has a definite seasonal prevalence during the south-west monsoon. Cases are practically confined to adult males engaged in outdoor occupations which involve working in water and mud for prolonged periods. Samples of standing water from paddy fields, swamps, etc., in different parts of the Settlement were examined for pH. Leptospiras were found in most water samples at pH 6.9 or over, and were absent from those with a more acid reaction than pH 6.9. The reaction of soil and water in parts of the Settlement appears to be that which has been found suitable for persistence of leptospiras and associated with the occurrence of leptospiral infections in other parts of the world. Infection is widely scattered and not as a rule of marked intensity in any one area. Occasional concentrated outbreaks may occur. In 1 outbreak, onset of the first case 6 days after commencement of work in swampy ground and the occurrence of the last case 8 days after work was stopped, determines the incubation period and definitely associates the disease with conditions involving prolonged immersion in mud and water. Rats, considered to be possible carriers, were absent from the paddy fields during the epidemic season in the monsoon. A small number obtained from certain areas showed no leptospiras in their kidneys. Suggestions for prophylaxis are made.—*J. Taylor.*

10723. **TSURUMI, MITSUZO.** Études sur la fièvre scarlatine. *Office Internat. Hyg. Publ.: Bull. Mensuel* [*Paris*] 22(5): 929-931. 1930.—These notes are based on 10 yrs.' work by **T. TOYODA** at Dairen, Manchuria,

where a scarlatina epidemic occurs nearly every year. Toyoda concludes that in the culture filtrate of the streptococcus isolated from scarlatina (Dick toxin) there is a mixture of thermolabile and thermostable toxins. The pure thermolabile toxin contains no N and is easily destroyed by heating to 80° for 30 min.; it is responsible for all the symptoms of onset of scarlatina. Used intracutaneously, it produces a very strong reaction in non-immunized persons, but no allergic reaction. The thermostable toxin is unaffected by heating to 100° for 2 hrs.; used intracutaneously, it often produces an allergic reaction in persons immunized against scarlatina. Uniform and exact results with the Dick test are obtainable only by using the thermolabile toxin. Intracutaneous test with thermolabile toxin indicates the exact degree of a person's susceptibility to scarlatina; the parallel test with thermostable toxin indicates clearly the degree of a person's immunity. The thermostable toxin gives intracutaneous results identical with those of the endotoxin extracted from the streptococcus on alkali-acetic acid treatment. Streptococci are present in the throats of 14% of healthy persons giving a positive Dick test; the number of colonies and the proportion of toxin are not the same. The scarlatinal streptococcus is distinguished from other hemolytic streptococci only by its toxic productivity, superior to all others except that of erysipelas. Toyoda has produced scarlatina experimentally in man by inoculation with the scarlatinal streptococcus. He rejects the theory of a filtrable virus, and also the theory that there is another active factor besides the streptococcus.

10724. VERROTTI, G. Ricerche sperimentali di superinfezione sifilitica nell'uomo. [Syphilitic superinfection in man.] *Boll. Soc. Ital. Biol. Sperim.* 3(5): 572-573. 1928.—Experiments were made on 2 patients, 1 with exogenous, the other with both exogenous and autogenous material. The exogenous inoculations were successful, the autogenous were not. The character of the lesions was that of the stage of the disease in the inoculated patient. *Treponema pallidum* was found in the experimental lesions of one patient but not in those of the other. It is suggested that in the latter the *Treponema* may have taken another than the spiral form. In one patient the spontaneous lesions near the experimental lesions healed on full development of the latter, suggesting the elaboration of a vaccinating substance.

10725. WERMEL, E. M. Reaktion der Zellen auf Tuberkelinfektion in den Gewebskulturen. *Virchow's Arch. Path. Anat. u. Physiol.* 281(2): 297-315. 15 fig. (10 col.) 1931.—The cultures used were splenic tissues from an adult guinea pig and endocardial tissue from a guinea pig embryo 25 mm. long. Only histoid cells and polymorphonuclears were actively and in important numbers engaged in phagocytosis of BCG; neither lymphocytes nor connective tissue cells took part. The polymorphonuclears and a part of the histiocytes which engulfed BCG perished. If the cells were able to conquer the infection, BCG formed clumps in the cell body, became surrounded by a vacuole and were transformed into a dark-yellowish brown pigment which later became blackish brown and granular. He concluded that the epithelioid cell is not a specific kind of cell but an overgrown macrophage, which may be called an epithelioid macrophage. Epithelioid cells, like giant cells, are readily formed on infection of cultures with tubercle bacilli. The formation of giant cells can not be regarded as a specific reaction. Infection of tissue cultures with tubercle bacilli may have either one of 2 possible results: The engulfed bacilli may destroy the cells and supplant the culture, or the cells may destroy the bacilli and work them up into pigment. Only one author (Fischer) has yet observed a protracted coexistence of both elements.

10726. WHERRY, W. B. Cultivation of an acid-fast bacillus from leprosy. *Philippine Jour. Sci.* 43(4): 577-581. 1 pl. 1930.—An acid-fast bacillus was grown in a semisolid medium composed of equal parts of nutrient agar, and hen's ovomucoid and yolk, prepared by boiling in 3-6% glycerin, when there was added to this 1-2 drops of oleic acid and 1-2 drops of 10% dextrose solution for each cc. of medium. Multiplication occurred best at 35-37° C., with little O but with CO_2 present. Examination after 4-6 wks.' incubation showed numerous microscopic colonies. Growth was obtained from 3 cases. From 2 of the primary cultures, subcultures were obtained at a time when the primary cultures were 3½ mo. and 1 mo. old, respectively. Like the lepra bacilli in smears from cases, the cultivated bacilli do not stain by the acid-fast method if they are first treated with xylol and alcohol.—*Author's summary.*

10727. WOLFF, L. K. Ueber die Virulenz von Bakterien. I. Die Virulenz von Staphylokokken. *Zeitschr. Immunitätsforsch.* 62(1/2): 1-27. 1929.—When staphylococci are inoculated into rabbit corneas they produce effects which vary with, and are characteristic of, their virulence. When the infection goes on to panophthalmitis the bacteria gradually increase in virulence. By taking cultures at successive intervals from the resulting abscess in the vitreous humor of such eyes, the author obtained a series of cultures varying in virulence, as determined by inoculation into rabbit corneas. The more virulent cultures lose their power to hemolyze rabbit and human blood and to liquefy gelatine. They are more resistant to the bactericidal action of serum, even the immune serum of rabbits. Increase in virulence is not due to lessened susceptibility to phagocytosis or to increase in amount of leukocidin produced; it is thus probably due to increased resistance to lysis. Cultures from various pathologic conditions vary but little in their effects on the eye, but a culture from normal skin was less virulent both by in vivo and in vitro tests.—*E. C. L. Miller.*

10728. WOLTERS. Über den Nachweis von Tb.-Bakterien in Lungenschleim- und Milchproben durch Züchtung. *Deutsche Tierärztl. Wochenschr.* 39(35): 547-548. 1931.—From animal sputum and milk samples with microscopically positive reaction, tubercle bacilli were always cultured; frequently also from microscopically negative material. Therefore, suspected cases should be tested by the culture method, even though microscopically negative. For demonstration of avian tuberculosis in sputum and milk samples, the culture method also is very important.—*Author's summary (transl.).*

10729. [ZABOLOTNOV, P., and B. SHMIDT.] ЗАБОЛОТНОВ, П., и Б. ШМИДТ. К морфологии экспериментальной легочной чумы. **[Experimental pulmonary plague.]** Вестник Микробиологии, Эпидемиологии и Паразитологии (*Rev. Microbiol., Épidémiol. et Parasitol.*) 9(2): 155-168; German summary, 280. 1930.—10 guinea pigs were infected by inoculation of plague bacillus emulsion and killed on the 1st, 2nd, 3rd and 4th days following. The lungs, after 24 hrs., showed slight hyperemia, with swelling of the alveolar epithelium; no plague organisms were found. After 48 hrs., a more pronounced hyperemia, exfoliation of the epithelium of the bronchial tubes and bronchioles, and the appearance of very small pneumonic foci with hyperemia and accumulation of serous exudation, were observed; plague bacilli were not numerous. After 3 days, pneumonic foci of considerable size were observed, and the alveolae contained plague bacilli, this being the first evidence of pulmonary plague. After 4 days were noted general plague infection, and also primary catarrhal plague pneumonia, as in the previous case. In all cases, when lymphatic knots appeared, they were of secondary bubonic character. After the infection of the lungs, changes in the liver and spleen were also observed. The general picture of plague differed slightly from that in man. Intracardial infection, in general, gave the same results.—*G. A. Lebedeff.*

10730. ZEISS, HEINZ. Die pestähnlichen Lymphdrüsenentzündungen in Russland 1876/79 und ihre Beziehungen zur Tularämie in der Sowjetunion 1921/28. Eine seuchengeschichtliche Untersuchung. [Plague-like

inflammations of the lymph glands in Russia (1876-1879) and their relation to tularemia in Soviet Russia (1921-1928).] *Arch. Hyg. u. Bakt.* 105(4) : 210-228. 1931. —The disease picture of tularemia in U. S. S. R. is showing more and more similarity to that of true plague.

10731. **ZOON, J. J.** Tierversuche mit Monilia fioccoi. *Dermatol. Zeitschr.* 61(4) : 232-238. 5 fig. 1931.—Intraperitoneal injection of human tissue emulsion, from which *M. fioccoi* had been isolated in pure culture or culture suspension, into about 50 rats, into mice, 4 guinea pigs, and into rabbits, produced no local inflammation or metastatic foci; small amounts disappeared entirely, larger quantities were encapsulated by the omentum; the microorganisms lived for a long time and formed mycelia. 1 intratesticular and 1 subcutaneous injection into rats and 1 intravenous injection into a rabbit were negative. A positive culture on glucose agar was obtained from an encapsulation in a rat injected 10 wks. previously with a living suspension; animal transfers of this gave the same result as the original injection.

10732. **ARMSTRONG, CHARLES.** Psittacosis: epidemiological considerations with reference to the 1929-30 outbreak in the United States. [*U. S.*] *Public Health Repts.* 45(35) : 2013-2023. 1930.—169 cases with 33 deaths (exclusive of 16 laboratory infections) are noted from 15 states and the District of Columbia. The affection followed exposure to parrots, parrakeets and canaries in 55, 4 and 3 foci, respectively. Incriminated birds came from Brazil, Colombia, Cuba, Nicaragua, Honduras, Germany, Trinidad, Salvador, Mexico and Japan. Several cases followed exposure to apparently well birds. Intervals from first exposure to onset of symptoms were 6-8? days. Incubation periods are given as 6-15 days; 63% of the cases were females. No deaths were reported among 35 cases under 30 yrs. of age; 24% over that age died. Phlebitis was the commonest complication.—*C. Armstrong.*

10733. **AYYAR, C. V. RAMASWAMI.** Biological oxidation of sulphur, Part IV. Influence on ammonification and nitrification in activated sludge. *Jour. Indian Inst. Sci.* 13A(14) : 165-171. 4 fig. 1930.—The effect of sulphur-oxidation on ammonification and nitrification in suspensions of activated sludge is discussed. The suspensions contained in jars were maintained under vigorous aeration, using compressed air. Changes in reaction, and in type and number in the microflora, were studied and correlated with these observations. Results indicate that in presence of S, nitrification is completely inhibited (pH 5·8), but ammonification, brought about largely by fungi, proceeds vigorously almost to the end. The possible bearing of these observations on their application to the purification of sewage, with special reference to the conservation of plant nutrients in the sludge, is indicated.—*C. V. R. Ayyar.*

10734. **BALLANTYNE, E. N.** On certain factors influencing the survival of bacteria in water and in saline solutions. *Jour. Bacteriol.* 19(5) : 303-320. 1930.—Various bacterial emulsions remained viable for 5-32 mo. in 0.85% NaCl at various temp., and 14-32 mo. in distilled water. The bacterial concentration required for survival of *B. typhosus* in emulsion in distilled water or in 0.85% NaCl for a given time at a given temp. can be approximately determined. This varies greatly with temp. and emulsifying fluid employed. Distilled water is a more favorable medium for survival than 0.85% NaCl for *B. typhosus, B. coli, B. tuberculosis, B. diphtheriae, Strep. hemolyticus, Strep. viridans,* etc. Prolonged survival of *B. typhosus* in distilled water and in 0.85% NaCl is associated with a late period of comparatively low death rate. In *B. typhosus* at 37° C., onset of a period of low death rate may be detected after about 3 weeks. The fact that *B. typhosus* in distilled water survives so much longer at room temp. than at 37° C. points to low temp. as a factor of considerable importance in production of winter river typhoid in temperate climates. Washing *B. typhosus,* either in 0.85% NaCl, or in distilled water, shortens its survival period when resuspended in these fluids. The supernatant fluid removed in washing prolongs the survival period of the relatively few bacteria inevitably present. Great dilution of an emulsion of bacteria appears to be almost equivalent to washing in its effect. 10-20% plain nutrient broth diluted with 0.85% NaCl is the optimum concentration for prolonged survival of *B. typhosus* at 37°; 0.1% is sufficient definitely to prolong survival. 0.85% NaCl appears to be toxic to certain organisms when stored in nutrient media at 37°. Reduction in concentration of NaCl in culture media might assist in preservation of cultures of certain delicate organisms. Room temp. appears to be more favorable for survival of most organisms in distilled water and in 0.85% NaCl than 0°-8°. Streptococci and *B. diphtheriae* are exceptions. Duration of survival of several of the Gram-negative bacilli appears to be more uniformly long in distilled water and in NaCl solutions than on solid media.—*Author's summary & conclusions.*

10735. **BARKWORTH, H.** True time required for sterilization. Hot air and flowing steam. Time and temperature combination required for sterilization in the hot air oven, and a note on the time required for media to reach 100° C. in the steamer. *Zentralbl. Bakt. II. Abt.* 84(15/18) : 353-357. 1931.—The temp. recorded by the ordinary thermometer was unrelated to that of glassware within closed containers. Growth of *B. subtilis* spores was used as a criterion of sterility. When glassware was packed in closed tins, the minimum exposure required was 2 hrs. to reach 160° C., followed by 1 hr. at 160°; but if the lids of the containers are left off, the time could be reduced by 1 hr., i.e., 1 hr. to reach 160° C. followed by ½ hr. at 160° C. For routine work, an extra ½ hr. should be added to the holding period. The temp. on the shelf is significantly lower than that attained on the bottom. In an ordinary steam sterilizer, the liquid (3 liters) did not attain 100° C. until 25 min. after the surrounding steam.—*From author's summary.*

10736. **BLUMENFELD, FELIX.** Wetter und Erkrankungen der oberen Luftwege. *Folia Oto-Laryngol. I. Abt. Orig.* 19(2) : 185-193. 2 fig. 1930.—The author points out the futility of statistical studies of the relation of diseases to single phases of weather, e.g., temp. or humidity. Under the conditions in Middle Europe, the polar, tropical, maritime and continental air-bodies are important in studies of the effects of weather on health. Characteristics of each are given. Invasions by tropical or polar air-bodies are especially important. Observations of others are reviewed.—*W. A. Sawyer.*

10737. **BOYÉ.** Les relations entre la peste pulmonaire et la température. *Office Internat. Hyg. Publ.: Bull. Mensuel* [*Paris*] 22(2) : 274-276. 1930.—Pulmonary plague is frequent in the cold plateaus of Madagascar and extremely rare (never endemic) in the hot coastal regions. No epidemics have ever been observed in regions of Madagascar where the absolute minimum of temp. is not maintained for several days at a time below 16°.

10738. **BREWER, C. M., and G. L. A. RUEHLE.** Limitations of phenol coefficients of coal-tar disinfectants. *Indust. and Engineer. Chem.* 23(2) : 150-152. 1931.—

Tabulated data on 172 coal-tar disinfectants and 34 cresol compounds are given. *B. typhosus* phenol coefficients of coal-tar disinfectants (0.66-19.5) were 2-20 times greater than the corresponding *Staph. aureus* coefficients; with cresol disinfectants, 1-2.5 times the *Staph. aureus* coefficients. This demonstrates the impossibility of calculating germicidal efficiency of coal-tar disinfectants against other types of microorganisms, from the *B. typhosus* phenol coefficient.—*C. M. Brewer.*

10739. **BROMBERG, I. M., and R. COMAROFF.** Epidemiology of typhoid fever. Incidence of typhoid carriers in a general population group. *Jour. Hyg.* 29(2): 139-145. 1929.—Of 484 inhabitants of a village in Palestine, 0.62% were carriers. Prevalence was not influenced by season. Brilliant-green-MacConkey agar was most satisfactory for plating of feces, brilliant-green-glycerine for shipment, and Kligler's lead-acetate-triple-sugar medium for differentiation. Zinc loops in shipment bottles inhibited growth after 24 hrs.—*A. L. Stoughton.*

10740. **BRUHNS, C., und A. ALEXANDER.** Mykologische Beiträge. *Dermatol. Wochenschr.* 91(33): 1250-1253. 2 fig. 1930.—An atypical form of *Epidermophyton inguinale* (*Trichophyton interdigitale*), non-pathogenic for animals, is described. The source and distribution of dermatophytes in nature are discussed. Sporotrichums are abundant around Mount Blanc; *Actinomyces* spp. occur on grain. This saprophytic life is confirmed by demonstrations that the dermatophytes can exist in cultures on dry wood, awns of grains, dung and garden earth. Animals are also a source; 13 fallow deer in a park in Padua were found affected with trichophytosis. A patient who handled straw in packing wine bottles developed trichophytosis of the nail. The authors secured a culture of *Achorion schoenleinii* from a cicada from Berlin; this points to the grass, grain and stagnant water constituting the environment of this insect as a source in nature for this fungus. Ciferri is quoted as having found a *Grubyella* from a gnat; *Achorion schoenleinii* again is a member of the genus *Grubyella*.—*F. D. Weidman.*

10741. **BRUHNS, C., A. ALEXANDER, und E. KADISCH.** Zur Kenntnis der Infektionsquellen bei Pilzerkrankungen der Haut. *Med. Klinik.* 25(46): 1769-1771. 4 fig. 1929.—Whereas most of the fungus diseases common during the war were of deeply invasive type, such as folliculites, at present the superficial ones exemplified in dermatophytosis are the problem. In addition to such intertriginous positions as fingers and toes, the authors have seen submammary involvement. The commonest causes are *Trichophyton interdigitale, Epidermophyton inguinale,* and the thrush fungus ("Soorpilz"). Tissue changes induced are of the same order regardless of exciting agent. Since bathing houses have been suspected as a source of infection, the author tested whether associated materials could support growth of dermatophytes. The substrates employed were silk, wool, leather, straw, feathers, wood, earth, turf, hay, rubbish and manure. The species tested were as follows: *Trichophyton cerebriforme, T. radiolatum, T. interdigitale, Epidermophyton inguinale, Achorion quinckeanum,* and *A. gypseum.* While there were differences in luxuriance, in general the substances named were adequate to support growth. The authors comment on the ease with which the center of a bundle of laundry can escape disinfection and on the problem of disinfecting silk and wool, which is even more difficult of solution. A further factor favoring recurrences is the superficiality of the affection, which is not calculated to call forth immune body production. Incidentally, the optimum temp. for these organisms (27° C.) approximates that of bathing establishments, in which the disease appears to be contracted.—*F. D. Weidman.*

10742. **BÜRGERS.** Studien zum Erkältungsproblem. *Schrift. Königsberg. Gelehrt. Ges., Naturwiss. Kl.* 6(3): 81-100; also publ. by Max Niemeiger: Halle a. S., 1929. Price 2.40 M.—The extensive literature on the relation of exposure to cold with incidence of respiratory infections is reviewed, and 42 references are quoted. Original experiments are also described. 49 guinea pigs orally injected with pseudotuberculosis were exposed to cold for 1 hr. at a time (air −7° to +9.5°). These exposed animals lost weight and 13 died of pneumonia; 14 injected controls not so exposed to cold showed no such lowered resistance to other organisms. Exposure to cold of normal guinea pigs or of others which had lost weight by being fed a diet low in vitamins, very rarely gave rise to pneumonia. Another series of 36 guinea pigs was inoculated nasally with 2 types of pneumococci; 18 were exposed to cold and the others were used as controls. Pneumonia was not seen. Experiments on man were undertaken, degree of cooling being estimated from thermometer measurements of surface temp. on fingers and toes. Local cooling of hands or feet was obtained by water baths, wind on wet stockings, or by snow; general cooling, by variations in the room temp. Local cooling gave skin temp. as low as 14-22°, which might persist for 45 min. or longer after local cooling was discontinued, if the room temp. was low. Metabolism was measured and intense local cooling was found to be much less effective in producing increase in metabolism than weaker cooling applied to the whole body surface. However, local cooling produced vasomotor changes in other areas, with fall of surface temp. Exposure produced a considerable diuresis. General cooling was associated with a shrinking of the nasal mucosa; warming, with a swelling and decreased or increased secretion. The effect appears to depend on direct exposure of the nose to cold. Such exposures were not followed by bronchial infections; a bronchitis and slight nephritis in one case and an increase in sciatica in another, which followed exposure, are ascribed to chance. Opsonic measurements were made both on man and on rabbits. In rabbits, cooling gave a lowered opsonic index, but the bactericidal power of the serum was unchanged. Results indicate that infection depends on a decrease in protective substances, probably through changes in the nasal mucous membrane and its secretion.—*H. C. Bazett.*

10743. **CAZANOVE.** Recherches sur les causes de la persistance de la peste au Sénégal. *Office Internat. Hyg. Publ.: Bull. Mensuel* [*Paris*] 22(11): 2103-2107. 1930.—Fleas (*Xenopsylla cheopis*) from mice infected with plague, ground up into an emulsion and subcutaneously injected into other mice, transmitted plague. The author concludes that fleas as well as rodents may be reservoirs of plague in Senegal.

10744. **DOUBROWINSKY.** La tularémie dans l'Union des Républiques Soviétistes Socialistes (1921-1929). *Office Internat. Hyg. Publ.: Bull. Mensuel* [*Paris*] 22(10): 1911-1921. 1 map. 1930.—The author holds the water rat (*Arvicola amphibius* L.) chiefly responsible for the occurrence of human tularemia in the U. S. S. R., though he admits that the part which may be played by other rodents as reservoirs of the virus is as yet uncertain. Epidemics follow the opening of the water rat hunting season; they cease after its end. The river basins (almost exclusively the ♂ population 10-30 yrs. old) are the regions affected; but Saratoff, where the water rat is not hunted, has never known a case of tularemia. The dried skins of the rat do not appear to convey infection.

10745. **ELDRIDGE, E. F., and W. L. MALLMANN.** I. Influence of diluting water on the biochemical oxygen demand. II. Digestion of sludge from strawboard waste. *Michigan Engineer. Exp. Sta. Bull.* 39. 1-14. 1931.—I. A bacteriological and chemical study of diluting waters for biochemical oxygen demand (B.O.D.) determinations showed that a synthetic water containing the mineral salts common to natural waters was superior to distilled, bicarbonate, carbonate and phosphate waters. Both tap-water and synthetic water gave much higher B.O.D. results and bacterial counts than the others mentioned. A marked lag phase both in B.O.D. and bacterial activity was found in distilled, carbonate, bicarbonate and phosphate waters. The curves produced by plotting the B.O.D. values paralleled those made by plotting the bacterial counts. The phosphate water gave trouble be-

cause of its effect on iodine liberation in the dissolved oxygen determination, thus rendering accurate results difficult. 2 limiting factors were found—pH value and mineral salt content. II. Strawboard sludge was mixed with sewage sludge and the rate of digestion, as indicated by gas production, was studied. 1:1 mixture of the 2 sludges gave the largest volume of gas per unit weight of sludge, with the exception of the sample containing sewage sludge alone. The volatile matter decrease was about the same in all mixtures. Rate of gas production was prolonged according to proportion of straw sludge added. The 1:1 mixture was about optimum for rate of digestion.—*Authors' summaries.*

10746. GAFAFER, W. M. The inhabitants of the island of St. Kilda and acute upper respiratory disease. *Human Biol.* 3(3): 437-441. 1931.—This paper consists of excerpts dealing with upper respiratory disease epidemiology from K. Macaulay's rare 18th century "History of St. Kilda." The title-page of the work is reproduced, and adequate footnotes are added.—*W. M. Gafafer.*

10747. [GAISKIĬ, N. A.] ГАЙСКИЙ, Н. А. Вопросы эпидемиологии и эпизоотологии чумы в связи с особенностями природы Казакского Края. **[Epidemiology and epizootic of plague in connection with peculiarities of natural conditions in Kazakstan.]** Вестник Микробиологии, Эпидемиологии и Паразитологии (*Rev. Microbiol., Épidémiol. et Parasitol.*) 9(1): 1-9; French résumé, 125-126. 1930.—The marmot, being widely distributed beyond the boundaries of the endemic region, becomes a dangerous carrier of plague only under definite geographical, climatic and soil conditions.—*G. A. Lebedeff.*

10748. GARRIDO-MORALES, E., and O. COSTA MANDRY. Mechanism of natural immunity to diphtheria. Preliminary report of experiments in Porto Rico. *Amer. Jour. Hyg.* 14(1): 89-98. 1931.—Schick tests of 642 children in one of the larger public schools in San Juan showed higher proportions of Schick-negatives than usually found at corresponding ages in New York, Baltimore, and other cities in northern U. S. A. This accords with previous observations in the tropics. Bacteriological examinations made at the time of the first Schick tests (March 1930) showed 1-4% to be carriers of virulent, and 5.8% to be carriers of avirulent, diphtheria bacilli. Carrier infections with both virulent and avirulent organisms were somewhat more frequent in Schick-positive than in Schick-negative children. Bacteriological examinations of 194 originally Schick-positives, repeated weekly for 3 mo. (March-June, 1930), showed a total of 26 carriers of virulent, and of 42 carriers of avirulent, diphtheria bacilli. All carrying virulent organisms were previously or later found to harbor avirulent bacilli. During the 3 mo. of observation, negative Schick reactions developed in 85% (22 of 26) of the demonstrated virulent carriers, in 12% of those carrying only avirulent organisms, and in 9.5% of those showing no positive cultures. Of the 4 demonstrated carriers of virulent organisms remaining Schick-positive at the end of June, 2 showed negative, and 2 positive, reactions, when retested the following September. 20 of the 22 known carriers of virulent bacilli who had developed negative Schick reactions before June 30, were retested 3-5 mo. later. 16 of the 20 were still Schick-negative; the remainder were positive. The completeness and durability of the negative Schick reaction developing after demonstrated infection with organisms classed as virulent, showed some relation to degree of toxicity of cultures.—*Author's summary.*

10749. GRAHAM, R. R. The farm water supply, wells and their construction, springs, cisterns, pumps, hydraulic ram; and water supply, plumbing and sewage disposal systems for farm homes. *Ontario Dept. Agric. Bull.* 361. 1-72. 58 fig. 1930.

10751. HALE, FRANK E. Successful superchlorination and dechlorination for medicinal taste of a well supply, Jamaica, N. Y. *Jour. Amer. Water Works Assoc.* 23(3): 373-386. 1931.—Medicinal taste with chlorination developed in a well supply, caused by organic substance possibly extracted from the ground by leaking gasoline from a garage. *Crenothrix* was a possible source. Coal and coke were eliminated. Experiments proved that the taste was prevented by boiling before chlorination, by oxidation as by H_2O_2, by long standing, partially by aeration, by addition of 0.2 p.p.m. of NH_3 prior to 0.4 p.p.m. of Cl, by superchlorination, and by activated charcoal. Superchlorination of wells and dechlorination by SO_2 in the pump well was adopted because of quick application, little additional equipment needed, and ease of control. Residual Cl, 0.03 p.p.m. by orthotolidin test, was maintained in the station discharge. Superchlorine dose was 1.6 p.p.m. and SO_2 dose, 0.6 p.p.m.; effective superchlorine contact 5-10 min.; total possible Cl contact 26-34 min.; average station discharge 3½ m.g.d. The treatment was entirely successful over 8 mo.—*F. E. Hale.*

10752. HASLEY, D. E. Brucella abortus in certified milk. *Jour. Infect. Dis.* 46(5): 430-434. 1930.—In an effort to determine the feasibility of using plating methods to detect the presence of *Br. abortus* in market milk, the authors examined 230 samples of certified milk as sold by 5 dairies in Detroit, Michigan. *Br. abortus* was isolated and identified in 4.3% of the samples analyzed. Milks from 3 of the 5 dairies were shown to contain the specific organisms. It was later found that 1 of the 2 dairies from which negative results were obtained, had previously eliminated all abortion reactors. The average number of organisms of the *Brucella* group found in these samples was 2 per cc.; the highest, 8. The comparatively low numbers are probably due to use of mixed herd milk for the samples.—*A. C. Fay.*

10753. HERRMANN, E. Carvasept und seine Verwendbarkeit. *Pharmazeut. Zentralhalle Deutschland* 72 (39): 613-614. 1931.—"Carvasept" (nomochlorcarvacrol) is 130 times as effective against staphylococci as phenol. In a dilution of 1:5,000 it kills *Spirochaeta pallida* in 2 min. Prophylactic salve preparations are equally efficient. It is also an anthelmintic and is recommended for skin infections.

10758. JORDAN, H. E. Factors contributing to quality of public water supplies. *Indust. & Eng. Chem.* 21(2): 152-156. 1929.—In the average American city, close to 100 gal. of water are used per person per day. Of this amount a little over 30 gal. are for domestic purposes. Only 0.5 gal. per person is taken internally. However, this relatively small amount is by far the most important single influence in determining the quality

of a public water supply. An analysis of the requirements to obtain the demanded quality shows that 5 factors must be considered. The most important of these is that of safety. Using the figure of 100 to represent the ideal quality, 51 points should be allowed for safety. In general, American public water supplies meet this requirement. The next 2 important factors are those of taste and "chemical balance," to which 22 and 20 points, respectively, should be assigned. Appearance should receive 5 points and temp. 2. Those engaged in furnishing water to the public would do well to take such a rating seriously.—*J. F. Norton.*

10759. **JOST, A. C., and NEIL E. McKINNON. Epidemiology and vital statistics.** *Canad. Publ. Health Jour.* 19(1/2): 234-237. 1928.—The authors, reviewing the report for the city of Hamilton for the preceding 2 yrs., emphasize the marked decline in mortality and morbidity rates of diphtheria, following the active immunization against diphtheria started in 1922,—over 60,000 inoculations being given in 1927. In the Province of Ontario, rabies has increased and is considered a serious problem. 136 rabies vaccine treatments were given during the year and 7 heads positive for rabies were found. The outbreak is not confined to one area, but several scattered foci have been demonstrated.—*C. H. Halliday.*

10760. **KADISCH, E. Über die Desinfektionswirkung einiger Waschmittel auf pathogene Hautkeime.** *Dermatol. Wochenschr.* 90(15): 514-517. 1930.—In view of the widespread use of the lukewarm laundry technique for wool and silk clothing, assisted by special soaps like Lux, the author tested the susceptibility of *Achorion gypseum, Trichophyton interdigitale, T. granulosum,* and *T. asteroides* in presence of Lux and Persil (the latter is probably a proprietary German washing powder). 3 of the species were killed at 56° C. in 3 min. The author concludes that in spite of the greater susceptibility of fungi for heat as compared with many pathogenic bacteria, and in spite of the associated influences of these laundry agents, neither the lukewarm nor the cold techniques kill the organisms. There is therefore the possibility that clothing such as stockings are genuine sources of re-infection in dermatophytosis. Detailed protocol is given of the results at the following temp.: 20°, 30°, 35°, and 56°, and over graded periods of 3-30 min.—*F. D. Weidman.*

10761. **KÄLIN, A. Ueber Hydrargyrum oxycyanatum und Compressi Hydrargyri oxycyanati.** *Pharmaceut. Acta Helvetiae* 6(8): 159-170. 1931.—A 0.5‰ solution of Hg-oxycyanide kills *Staphylococcus pyogenes aureus* in a water suspension within 30 min. A 1‰ solution kills them within 15 min. Addition of NaCl diminishes these times to 15 min. and 5 min., respectively. When suspended in 1% peptone water, the 0.5‰ solution did not kill in 1 hr., while the 1‰ solution killed within 30 min. Here the addition of NaCl is of no effect. For treating wounds and for disinfection of the hands and instruments, a 1‰ water solution is recommended.—*From author's summary (transl.).*

10762. **KHAN, SARANJAM, and MAHENDRA NATH AGARWAL. On the duration of the life of vibrios in the Ganges and Jumna river water.** *Indian Jour. Med. Res.* 16(4): 993-1008. 1928.—Water from these 2 rivers and from a well in Mela was used. Each sample was divided into 4 parts: (1) untreated, (2) boiled 5 min., (3) filtered through filter paper, (4) filtered and boiled. 2 vibrio cultures, one agglutinable and the other inagglutinable, were added to different portions of each sample. The flasks were kept at room temp. and cultures made on bile-salt-agar plates at regular intervals. Variations were noted in length of time cholera vibrios remained alive in different experiments, but in general the inagglutinable strain survived in unboiled water from the Jumna for 3.25 days; from the Ganges, for 7.25 days; from the well, for 3.62 days. When the water was boiled, the time was lengthened to 10.87 days for the Jumna; to 9.12 for Ganges; and to 8.75 for the well water. In each case, the agglutinable strain disappeared in a shorter period.—*T. G. Hull.*

10763. **KJER-PETERSEN, R. Tuberkuloseproblemer. I lys af 10 aars tuberkulosestationsarbejde. [Tuberculosis problems, in the light of 10 years' investigations at the tuberculosis station in Copenhagen.]** 125p. V. Thaning & Appel: Copenhagen, 1929. Pr. Kr. 3.50.

10764. **KLIEWE, H., und K. LANG. Über den Keimgehalt von Mineralwässern.** *Arch. Hyg. u. Bakt.* 105(2): 124-131. 1931.—Of 30 mineral waters tested, 3 were free of bacteria, 11 contained less than 100 per liter, the others up to 55,000. Most of the organisms were soil and water types; some indicated contamination by human and animal excreta. When held at 37° for 24 hrs., the bacterial content decreased markedly; at 17-22° there was an increase, followed by a gradual decrease.

10765. **KNAYSI, GEORGES. Disinfection. I. The development of knowledge of disinfection. II. The manner of death of certain bacteria and yeasts when subjected to mild chemical and physical agents. III. The taking up of iodine by yeast cells. IV. Do bacteria die logarithmically? V. Some properties of frequency curves and their use in studies of disinfection.** *Jour. Infect. Dis.* 47 (4): 293-333. 1930.—I. A review of the most important literature on the mechanism of disinfection. II. Disinfection curves were constructed for *Bacterium coli* in 1-1,000 aqueous solutions of methylene blue, in 1-1,000,000 aqueous $HgCl_2$ and in 75% glucose solutions. Similar curves were also constructed for *Schizosaccharomyces pombe* in 1-1,000 methylene blue. It is concluded that both organisms die in a similar manner and that in all cases the curves are more or less sigmoid in shape, belonging to the chance type. III. The cells of *Saccharomyces cerevisiae* take up iodine from its aqueous solutions according to the adsorption isothermal. IV. The so-called reaction constant k varies during the same experiment with a given culture, with cultures as much alike as is possible to have, and may be greater at a given temp. with a given culture than with a similar one at a higher temp. From this and other considerations it is concluded that bacteria and yeasts do not die logarithmically, as was assumed by Chick. V. The author worked out theoretical disinfection cases. Assuming that bacteria die according to the frequency distribution of their resistance, he constructs survivors' curves and finds that if obtained when the distribution curve of resistance is of the very skew or extremely skew types, they resemble very much the survivors' curves usually obtained by direct experiments.—*G. Knaysi.*

10766. **[KNYAZEVSKIĬ, A. N., and V. A. BERDNIKOV.]** КНЯЗЕВСКИЙ, А. Н., и В. А. БЕРДНИКОВ. О длительности сохранения вируса туляремии в шкурках грызунов. **[The length of time B. tularense remains active in the pelts of rodents.]** Вестник Микробиологии, Эпидемиологии и Паразитологии (*Rev. Microbiol., Épidémiol. et Parasitol.*) 9(1): 68-71; English summary, 132. 1930.—The pelts of house mice, rats, and guinea pigs dead from tularemia, were kept in a room at 7-8° C. and in a thermostat at 32-33°. 0.2-0.4 cc. of emulsion of 70 pelts kept at 7-8° was injected subcutaneously into house mice; emulsion of almost all pelts kept less than 26 days caused tularemia, as shown by patho-anatomical examination and by the presence of *B. tularense* in smears from the organs of dead mice. Emulsion from pelts kept 26-40 days gave a significantly lower % of infection; after storage for more than 40 days the organism apparently dies. When the pelts were kept in an incubator, the period of activity of the organism was significantly shorter; positive results with injected emulsion were obtained from pelts 2-5 days old; results were negative from pelts more than 5½ days old. There were no differences in results from emulsions made from pelts of house mice and guinea pigs.—*G. A. Lebedeff.*

10767. **[KOROBKOVA, E. I., S. V. MITIN, and I. V. RUBIN.]** КОРОБКОВА, Е. И., С. В. МИТИН, и И. В. РУБИН. Роль скарлатинозных носителей гемолити-

ческого стрептококка в эпидемиологии скарлатины. [Rôle of scarlatina carriers of hemolytic streptococcus in the epidemiology of scarlatina.] Вестник Микробиологии, Эпидемиологии и Паразитологии (*Rev. Microbiol., Épidémiol. et Parasitol.*) 9(2): 217-224; French résumé, 283-284. 1930.—*Streptococcus haemolyticus* was found in the mouths of all of 181 scarlatina sufferers during the most acute period of illness. In all cases, except one, the illness was caused by infection from other members of the family. Examination of 78 recovering patients showed that on the 22nd to 28th day the virus was present in 22-27% of the cases; on the 29th to 36th days in 19-24.3%; and on the 37th to 42nd days in only 15-19%. Examination of 83 families, to which 152 recovered patients had returned, showed that of the 100 recovered who harbored no streptococci on leaving the hospital, in only 1 case was there an illness in the family; while of the 52 who had streptococci on leaving the hospital, 3 cases of infection in the family occurred.—*G. A. Lebedeff.*

10768. **LEVINTHAL, WALTER.** Das Vorkommen des Pfeifferschen Influenzbacillus bei Gesunden. *Zeitschr. Hyg. u. Infektionskr.* 109(1): 93-95. 1928.—In cultures from throats of normal individuals, summers of 1927 and 1928, Pfeiffer's bacillus was found in 15 of 77 cases in the 1st series; in the 2nd series it was found in 32 of 75 individuals.—*W. W. Herrmann.*

10769. **MAXWELL, J. L.** The diseases of China, including Formosa and Korea. 2nd ed. 530p. 176 fig. H. K. Lewis & Co.: London, 1929. Price 20 s.

10770. **MINKEWITSCH, I. E.** Über einige Bodenstämme des B. coli und ihre sanitäre Bedeutung. *Zeitschr. Hyg. u. Infektionskr.* 111(1): 58-67. 1930.—Studies were made of *coli-aerogenes* bacteria isolated from 704 samples of earth collected at various latitudes of Russia from Kola (Arctic zone) to Batum (subtropics). Among the varieties of *B. coli-aerogenes* in soil cultures, *B. aerogenes* appeared no more often than in cultures of intestinal contents of man or animals. The anaerobic fermentation test apparently can serve as an indication of fecal soil pollution, as it gives positive results just where such pollution is demonstrable.—*W. A. Sawyer.*

10771. **MINKEWITSCH, I. E.** Die Grundtypen der Bacteriengruppe Coli-aerogenes und ihre Herkunft. *Zeitschr. Hyg. u. Infektionskr.* 111(2): 180-190. 1930.—255 specimens of common diptera, mostly mosquitoes and house-flies, were collected between Murman and Leningrad and examined culturally for bacteria of the *coli-aerogenes* group. Such bacteria were present in only 2% of the mosquitoes and in 8% of the flies (*Musca domestica*), and the strains peculiar to these insects would not interfere with the testing of water for colon bacilli, as such strains do not produce fermentation at 46° C. and can be differentiated from *B. coli* of fecal origin by Bulir's test or by Koser's citrate test. The gas-producing intestinal bacteria of lower vertebrates, such as fishes and frogs, have the same differentiating characteristics as those of insects. The origin in nature is stated for 5 basic types of the *coli-aerogenes* group.—*W. A. Sawyer.*

10772. **PACIATTI, C.** Relazione sull'esperimento di fermentazione e trasformazione delle immondizie provenienti dalla nettezza domestica e stradale nelle celle zimotermiche Beccari-Valtancoli per l'impianto della città di Patrasso, Grecia. 10773. **PAUL, JOHN R., and ROBERT SALINGER.** The spread of rheumatic fever through families. *Jour. Clin. Investigation* 10(1): 33-51. 1931.—Study of 15 families suggests that an infection is involved, in which the rôle of environment and hereditary predisposition are unknown. The sudden appearance of apparently primary and secondary outbursts in certain individuals was frequently accompanied by recognizable forms of the disease in other members of the family group, and not infrequently by the simultaneous appearance of non-specific illnesses, e.g., bronchitis, bronchopneumonia, skin rashes and rheumatoid arthritis. Not only do several cases seem to be initiated simultaneously, but periods of recurrent activity of the disease seem to sweep through a family in synchronous waves, during which time new cases may also appear.

10774. **PAUL, JOHN R.** Age susceptibility to familial infection in rheumatic fever. *Jour. Clin. Investigation* 10(1): 53-60. 1931.—In a selected population (99 members of 14 families in which 2 or more individuals had suffered with evidences of rheumatic fever), the disease spread particularly to the younger members of the family, and was largely distributed throughout the age group 5-12, reaching its peak at about the age of 7. Among children 5-12 yrs. old, who apparently had not previously suffered from any manifestations of the disease, rheumatic fever was acquired in association with familial exposure, at the rate of 25-35%. Among children 5-12 yrs. old, who had survived an initial attack, recurrences were noted in association with familial exposure at the rate of 35-60%, decreasing as age increased, but representing a markedly enhanced susceptibility during adolescence.

10775. **PIERAERTS, GEORGES.** Notes cliniques sur la "fièvre rouge congolaise." *Ann. Soc. Belge Méd. Tropic.* 11(2): 189-204. 1931.—The symptoms of red Congo or pseudo-dengue fever are given in detail. Endemo-epidemic in the Congo region, it appears to proceed by small, local thrusts, manifesting itself successively in the form of an epidemic of the household, of the quarter, and of the village,—2 successive cases in the same house generally being spaced about 10 days apart. A seasonal incidence exists but is not absolute. The most numerous cases occur in the rainy season; those occurring in the dry season in a group, however populated, have not given rise to epidemic proportions. From the theoretic viewpoint, the disease merits study from its possible relations to Central African dengue; practically, this study shows it to be a definite clinical entity among the numerous acute tropical fevers.

10776. **[PLAVSKAĬA, E. V.]** ПЛАВСКАЯ, Е. В. Эпидемия гриппа в Балхашском районе зимой 1929 г. [Grippe epidemic in Balkhash, Khirgiz SSR., winter of 1929.] Вестник Микробиологии, Эпидемиологии и Паразитологии (*Rev. Microbiol., Épidémiol. et Parasitol.*) 9(2): 225-230; English summary, 284-285. 1930.—76% of the population became ill, of which 11% died (mainly children and elders) during the epidemic among the Cossack population. Death in most cases was due to complications (pneumonia, pleuro-pneumonia, enteritis), explained by the unsanitary conditions, insufficient food and absence of immunity. Microscopic and bacteriological investigation of 12 cases showed, besides staphylococci, Fraenkel's diplococci; in no case was Pfeiffer's bacillus found.—*G. A. Lebedeff.*

10777. **[REZHABEK, ĬA. V.]** РЕЖАБЕК, Я. В. К вопросу о выборе в районе Зеленого острова места забора воды для строящегося Ростово-Нахичеванского водопровода. [Choice of site for the drawing of water for the new Rostov aqueduct.] [German summary.] Известия Государственного Микробиологического Института в Ростове на Дону (*Ber. Mikrobiol. Staats-Inst. Rostow-am-Don*) 4. 5-54. 1929.—13 chemical and 37 bacteriological analyses of water from 4 points of the Don River near Rostov were made Feb. 13 to June 24. The samples were taken 50 m. from the shore and at a depth of 2 m. Suspended matter at all 4 points varied from 7.1 mgm. per liter in Feb. to 77.84 toward the end of March, then diminishing to 44.0 toward June. These variations were found also for other constituents: Organic matter, 1.6 mgm. per liter in Feb., increasing to 141.6 toward the end of March, decreasing to 1.88 toward the middle of June; O content, 2.69 mgm. per liter, increasing to 5.88, decreasing to 3.33; dissolved O (at 0° C. and 760 cm. pressure), 6.12 mgm. per liter, increasing to 10.71, decreasing to 6.05; absorbed O, 0.76 mgm. per liter, increasing to 8.99, decreasing to 1.03. Loss through heating of dry matter varied from 119.4

mgm. per liter in Feb. to 50.0 toward June. Combined Cl varied from 75.24 mgm. per liter in mid-Feb. to 20.10 at the end of March, and again increased to 42.31 mgm. toward the middle of June. Bacteriological analyses were limited to bacterial counts and coli titer. During the period of freezing over (Feb. 15–March 15), total count in 1 cc. of water from all 4 points was 84-758; March 15–June 10, 6564-34,140; after the spring freshets (June 10-20), 166-1170. Coli titer was 1.0-0.01 on March 19 and 100-10 on March 27, showing that there are conditions other than seasonal changes which determine coli titer. The data are considered valuable only when all other conditions are taken into consideration, e.g., freezing over, flooding, rate and direction of flow, direction and velocity of wind, precipitation, topography, and general sanitary conditions.—*G. A. Lebedeff.*

10778. RIVIÈRE, R. D. de la, E. ROUX, et F. CAVALLIER. Pouvoir bactéricide, sur le méningocoque, du bleu de méthylène irradié ou non irradié. *Compt. Rend. Soc. Biol.* 106(10): 799-802. 1931.—The bactericidal power of 10 samples of methylene blue was tested by putting each in contact with an emulsion of meningococci for 3 hrs. Cultures were then made and incubated, being observed after 1, 2 and 3 days. Emulsions of meningococci were cultured on agar and incubated in the same way to see if they retained their vitality. The same procedure was followed for each sample after irradiation for 20 min. The bactericidal power, good without irradiation, was better after exposure to ultraviolet (active at a dilution of 1: 150,000 before irradiation and of 1: 300,000 after). Addition of cholesterin diminished the antiseptic power and produced no difference between irradiated and non-irradiated products. Neither amount of Fe in the dye nor of ozone generated by the ultraviolet apparatus affected the antiseptic power. 2 lots of rabbits and guinea pigs received an emulsion of meningococci intraperitoneally. One was then given 1 cc. of a 1% solution of medicinal methylene blue. After 15 min., samples of peritoneal fluid were cultured. Those from animals receiving only the bacteria were positive; the others were negative. Medicinal methylene blue is recommended as a treatment for meningococcus infections.—*E. Weiner.*

10779. ROCHAIX, A. Recherches sur la persistance et la disparition des germes pathogènes dans l'eau d'égout. *Ann. Hyg. Pub., Indust. et Soc.* 8(12): 669-675. 1930.—Sewage containing no acid or alkaline, toxic or antiseptic products was sterilized, placed in flasks, and inoculated with cultures of various pathogenic organisms, preserved at laboratory temp. and tested at various intervals by inoculation on peptonized bouillon. In the 1st experiment, typhoid bacilli, paratyphoid A and B, cholera vibrios and *Bacillus pyocyaneus* were alive at the end of 7 mo. 14 days; paratyphoid B and *B. pyocyaneus*, at the end of 20 mo. 8 days. In 2d and 3d experiments, cholera vibrios and typhoid bacilli survived in sterilized sewage water only 3 mo. 7 days, while in sterilized distilled water they lived for 6 mo. 23 days; in a 4th experiment, paratyphoid B survived for 112 days in sterilized sewage, while in sterilized distilled water it lived for 8½ mo. In the remaining 4 experiments, paratyphoid B, cholera vibrios and typhoid bacilli were tested in sterilized sewage water, survival of each by itself being compared with its survival in a mixed culture of saprophytic organisms. In each case the pathogenic organism lived longer in pure than in mixed culture, and in mixed culture the saprophyte survived the pathogen. These results indicate that, while sewage is in itself a good culture medium for pathogenic organisms, the "vital concurrence" of saprophytes must play a large part in the disappearance of the pathogens.

10780. [ROMANOV, P. V.] РОМАНОВ, П. В. Химико-бактериологическое обследование реки Воронежа в районе г. Воронежа. [Chemico-bacteriological study of the River Voronesh in the neighborhood of the city of Voronesh.] Воронежский Государственный Институт, Бюллетень Общества Естествоиспытателей (*Bull. Soc. Nat. Voroneje*) 2(3/4): 95-120. 1929.—31 chemical and 22 bacteriological analyses of the water taken from 8 localities in the river, covering 6 km., of which 14 were within the city limits, were made, and revealed the wide variations occurring in the different seasons of the year.—*G. A. Lebedeff.*

10781. RUSSO, CANIO. Recherches expérimentales sur l'épidémiogenèse de la peste bubonique par les insectes. *Office Internat. Hyg. Publ.: Bull. Mensuel [Paris]* 22(11): 2108-2120. 1930.—The author finds that dead rats are visited by different species of insects, not at random but in a regular order: first by the common fly (*Musca domestica*) and the blue fly (*Calliphora vomitoria*). When the fat begins to grow rancid, coleoptera of the genus *Dermestes* appear, and, at the beginning of brown liquefaction, those of the genus *Hister*. After destruction of most of the liquid products of putrefaction, other parasites of the genus *Tenebrio* and acarids of the genera *Glyciphagus* and *Tyroglyphus* attack and destroy the dissected ligaments, tendons and bones. The author proved that almost all of these insects (flies and acarids, but not *Dermestes* and *Hister*), after such infected meals, harbor living virulent plague bacilli. His next study was on the infectivity of insects fed on infected cereals. A pile of maize on which a rat had died of plague was found invaded by acarids, which, being killed in alcohol, and applied to the shaven abdominal skin of 2 guinea pigs, produced death by plague. These acarids, however, were nearly immobile and apparently would not migrate far. Larvae of the weevil, *Sitophylus granarius*, and of *Tenebrio molitor* proved susceptible of laboratory infection. Plague bacilli were isolated from ants which had fed on infected maize. Hence, it appears that a large number of insects are capable of conveying plague bacilli, though their infectivity is of short duration, both because the insects themselves are short-lived and because the bacilli soon disappear from their bodies.

10782. RUTH, EDWARD D. The elimination of taste and odor in the water supply of Lancaster, Pennsylvania. *Jour. Amer. Water Works Assoc.* 23(3): 396-399. 1931.—Equal parts of anhydrous NH_3 and Cl gas in the amount of 0.18 p.p.m. are being fed to the water, the anhydrous NH_3 being fed to the raw water before coagulation with $AL_2(SO_4)_3$, and the Cl to the finished water after filtration, results being extremely low bacterial counts, complete absence of taste or odor, and elimination of algal growths in the reservoirs.—*E. D. Ruth.*

10783. [SLAPIK, V. K.] СЛАПИК, В. К. О бациллоносительстве обслуживающего здорового персонала брюшнотифозных отделений. [Carrying of bacilli by the healthy personnel handling typhoid patients.] Вестник Микробиологии, Эпидемиологии и Паразитологии (*Rev. Microbiol., Épidémiol. et Parasitol.*) 8(4): 413-418; French résumé, 482. 1929.—In the feces of 1 of 24 employees bacteriologically studied, and on the handle of a bed pan out of 14 articles examined in the typhoid hospital, bacilli were found that resembled Eberth's bacillus, but differed in somewhat heavier growth and in relation to glycerine. Agglutination of these cultures with paratyphoid A and B agglutinating sera was negative; agglutination with typhoid-immune serum was positive. By immunization of 2 rabbits with vaccine of these cultures, previously killed by heating to 58° C. for 1 hr., agglutinating sera were obtained after 7 days. It is concluded that employees and fomites may serve in spreading typhoid.—*G. A. Lebedeff.*

10784. SMIT, JAN. De moeilijkheden van het bacteriologische drinkwateronderzoek. [Difficulties in bacteriological water analysis.] *Nederl. Tijdschr. Hyg., Microbiol. en Serol.* 6(1): 19-39. 1931.—The difficulties in interpretation of *B. coli* tests in water analysis are emphasized, when the results do not correlate with the known properties of *B. coli;* and stress is laid on the fact that the types of *B. coli* which can be cultivated from fermenting media often do not correlate with those present in the water under investigation, so that characterisation of the water according to types of *B. coli* isolated may give false results. The way-out of these

difficulties seems to lie in the adoption of the bacteriological methods of Clemesha, by which the quantities of water are estimated, that cause acid- and gas-fermentation in glucose and lactose broth at 37° C. Addition of Eijkman's test at 45° C. seems to be a very important improvement on this procedure, inasmuch as the widening of the acid-and-gas line in glucose and lactose is very much slower in Europe than in the tropics, but biological purification is strong enough to cause marked reduction of fermentation in glucose at 45° (Eijkman's test) in about 1 week. Pathogenic organisms are certain to have disappeared when the water shows this divergence of the Eijkman-line against the line of glucose and lactose, and the water may be considered safe. This view has proved correct in many instances.—*J. Smit.*

10785. **SOBERNHEIM, G., und E. DIETRICH. Über die Frage der Nachentwicklung von Bakterien im gechlorten Trinkwasser der Stadt Bern.** *Arch. Hyg. u. Bakt.* 105(2): 71-87. 1931.—The Cl added to drinking water in Bern (usually 0.1 mg. per liter) kept it bacteria-free or almost so for several days, even at room temp. If bacteria developed, it was only after the Cl was no longer of bactericidal strength (α-naphthoflavon test negative). Usually they appeared no earlier in samples protected from air than in those exposed. Water standing in the pipes was usually Cl-free and with abundant bacteria. The bacteria surviving chlorinization were harmless water types; in no instance was *B. coli* found. Typhoid bacilli were killed, as shown by some samples artificially infected with 3 million per cc.—*From author's summary (transl.).*

Angewandte chemische und physikalische Methoden. Teil 15, Heft 3, Lief. 358.]** P. 385-589. 25 fig. Urban u. Schwarzenberg: Berlin & Vienna, 1931.

10787. **STOCKS, PERCY. The mechanism of a measles epidemic.** *Lancet* 218(5563): 796-802. 1930.—A detailed statistical study of a measles epidemic in one of the London boroughs shows that as the epidemic spreads through the streets of an urban area, the first sign of its approach to any given district is a sudden rise of infectiousness in the cases which occur there. This signalizes the upset of balance between activity of the virus, seasonal influences, density and circulation of the population and the "communal immunity" of the child population at the moment. It is suggested, though the evidence is still inconclusive, that the last of these factors is rendered the most powerful in determining the interval between epidemics and also in bringing epidemics to a close, by virtue of a temporary latent immunization of most of the children who escape manifest attack, such immunity gradually waning and disappearing after about 2 yrs.—*P. Stocks.*

10788. **[SUVOROV, S. V.] СУВОРОВ, С. В. Опыт применения хлора и сероуглерода для дезинсекции и дезинфекции жилых помещений при чуме. [Disinfection of plague-infested dwellings with Cl and CS_2.]** Вестник Микробиологии, Эпидемиологии и Паразитологии (*Rev. Microbiol., Épidémiol. et Parasitol.*) 5 (3): 143-145; German summary, 232. 1926.

10789. **THOMSEN, AXEL. Om Kalvekastningsfeberens (Svingefeberens) Forekomst hos danske Dyrlaeger. [Occurrence of undulant fever in Danish veterinarians.]** *Maanedsskr. Dyrlaeger* 43(2): 46-56. 1931.—Up to April 1931, diagnosis of undulant fever had been made in only 6 cases among veterinarians in Denmark. All were young men who were taken ill shortly after they had commenced practising on cattle in abortus-infected stables. That the disease has not been ascertained among older veterinarians is quite in keeping with the fact reported by the author (and later confirmed by others) that nearly all veterinarians (ca. 94%) who had practised on cattle for more than 1 yr. have specific antibodies against *Bacillus abortus* Bang and are presumably immune. On the basis of the author's examinations, it is warrantable to regard undulant fever as a disease unknown in Denmark prior to 1925. The author discusses conclusions that may be drawn from this material, as to pathogenicity of *B. abortus* for man.—*A. Thomsen.*

10790. **[TIKHOMIROVA, M. M., and S. M. NIKANOROV.] ТИХОМИРОВА, М. М., и С. М. НИКАНОРОВ. Клещи - носители чумы. (Ticks as plague carriers.)** Вестник Микробиологии, Эпидемиологии и Паразитологии (*Rev. Microbiol., Épidémiol. et Parasitol.*) 9(1): 60-61; English summary, 129-130. 1930.—In 1929, in Kazakstan, 8 ticks (*Rhipicephalus schulzei* Ol.) were taken from a marmot (*Citellus pygmaeus* Pall.) dying of plague. 4 drops of emulsion of these ticks in physiological saline were injected into the abdominal region of a guinea pig, which died within 50 hrs. Post mortem examination showed pathological changes in the internal organs, typical of plague: in smears of all organs many bipolar rods were found, and culture gave an abundant growth of plague bacilli. Also, emulsion from 3 ticks (*Ixodes autumnalis* Leach) taken from an *Arctomys bobac* dying of experimental plague, when injected into the abdominal region of a guinea pig, caused its death within 3 days. Post mortem revealed an acute experimental plague. Cultures from the tick emulsion and from the organs of the dead guinea pig both gave *B. pestis.* The authors emphasize the importance of this newly discovered factor of plague endemia.—*G. A. Lebedeff.*

10791. **[VORONKOVA, M.] ВОРОНКОВА, М. Обследование на туляремию водяных крыс (Arvicola amphibius) в Астраханском районе. [Examination of water rats (A. amphibius) for tularemia in the Astrakhan region.]** Вестник Микробиологии, Эпидемиологии и Паразитологии (*Rev. Microbiol., Épidémiol. et Parasitol.*) 8(4): 433-434; English summary, 484. 1929.—258 water rats were caught in 1929 in 2 places near Astrakhan, where there was a severe epidemic of tularemia in 1926. Rats from both places showed enlargement and hyperemia of the spleen, enlargement of glands, and necrotic regions in the liver. Inoculation of guinea pigs and mice with extracts of organs from the rats caused typical tularemia in one case and negative results in another. Thus it is considered possible that the epidemic in 1926 was due to rats.—*G. A. Lebedeff.*

10792. **WEFRING, KARL WILHELM. L'existence de la tularémie en Norvège.** *Office Internat. Hyg. Publ.: Bull. Mensuel* [*Paris*] 22(10): 1908-1910. 1930.—Until 1929 tularemia had not been reported in Norway. In that year Thjotta discovered the 1st known case, and later, 11 others; infection seemed generally to come from rabbits. The author suggests, however, that the so-called "lemming fever" presents in man clinical features resembling tularemia. This fever occurs in the years when lemmings (*Myodes lemmus*) descend in myriads from the mountains into the valleys, polluting the streams and other waters with their cadavers and excreta. The intestinal tract of the lemming contains abundant bacteria of the paracoli and paratyphoid groups; but the organs show no tularemia-like changes. Because of the clinical picture in man, however, the author thinks that the lemming should be suspected until cleared, as a possible tularemia carrier.

10793. **WILHELMI, J. Zur Frage der Abschaffung bzw. Einschränkung der Desinfektion bei Diphtherie und Scharlach. [Discontinuance or limitation of disinfection in diphtheria and scarlatina.]** *Zeitschr. Desinfektions- u. Gesundheitswesen* 23(9): 381-398. 1931.

10794. **WILLIAMS, JESSE FEIRING, and DELBERT OBERTEUFFER.** Industrial hygiene for schools. 280p. McGraw-Hill Book Co., Inc.: New York, 1930.—This book describes in elementary form industrial health practices. The first 4 chapters are a brief résumé of Williams' textbook: "Personal hygiene applied"; 10 chapters are devoted to industrial hygiene. Chap. V deals with the changes made by the machine age in living and working habits, especially the effects of fatigue and monotony on the worker. Chap. VI calls attention to

general health hazards in industry, especially poor ventilation, poor lighting, unsanitary toilet facilities, improper seating, and overtime work. Specific health hazards such as dangers from anthrax, glanders, high air pressures, organic and inorganic dusts, lead and other industrial poisons are outlined in Chap. VII. Chap. VIII tells in an elementary fashion of the prevention of diseases. Chap. X outlines proper home hygiene. A very brief outline as to home care of sick is included. The organization of the industrial health service is described in Chap. XI, also its aims and scope. Simple first aid suggestions are given. Chap. XII states why regulation by the State of conditions of labor in industry is necessary to properly protect workers; 3 groupings of legislation are given. Recreation and leisure time activities are necessary, as is shown in Chap. XIII. The concluding chapter shows the worth of health in terms of production and individual happiness. Appendix A gives the New York State Department of Labor's health suggestions for working girls. Appendix B gives Emerson's weight-height tables from 6 to 18 yrs.; and the average, 7% under average, and optimum wts. for heights from 20 in. up. Appendix C lists the occupations exposed to lead; D, the health hazards of benzol; E, the industries most in need of accident prevention work; and F, the industries in which workers need eye protection.—*M. L. Ilsley.*

10795. **WILSON, W. JAMES, and E. M. McV. BLAIR. Further experience of the bismuth sulphite media in the isolation of Bacillus typhosus and B. paratyphosus B from faeces, sewage and water.** *Jour. Hyg.* 31(2): 138-161. 1931.—By the Old Standard Bi sulphite [Fe-containing] medium, *B. typhosus* was cultivated 44 times out of 50 examinations of stools of 50 typhoid patients and convalescents. By the same medium, *B. paratyphosus B* was cultivated 22 times out of 27 examinations of stools of 27 cases of paratyphoid. In 13 examinations of Belfast sewage in different months during 1928 and 1929, by the Old Standard sulphite media, *B. typhosus* was isolated on 10 occasions. In 2 examinations of Lisburn sewage *B. typhosus* was isolated. Although no special search for *B. paratyphosus B* was undertaken, this organism was isolated on 2 occasions from Belfast sewage. The viability of *B. typhosus* and *B. paratyphosus B* in sewage is longer than was suggested by work of previous observers. It has been possible to cultivate *B. typhosus* and *B. paratyphosus B* from the deposit of sewage stored in a bottle at room temp. for 3 wks. *B. typhosus* was once found alive at the end of 5 wks. For isolation of *B. enteritidis* Gaertner the media gave good results in examinations of feces from cases of food-poisoning. Details for preparation of the media and of various modifications are given. Addition of 4 cc. of a 1:10,000 solution of perchloride of mercury to every 100 cc. of the Bi media tends to inhibit growth of *proteus* strains and certain other organisms which develop from sewage and interfere with isolation of *B. typhosus*. With the fluid media described here *B. typhosus* has been cultivated 17 times out of 17 stools from typhoid patients, and 3 times out of 5 specimens of sewage.—*Author's summary.*

10796. **WIRGIN, GERMUND. Der Einfluss der Temperatur der äusseren Luft auf die Desinfektionswirküng von Formaldehyddämpfen in geschlossenen Räumen.** *Acta Path. et Microbiol. Scandinavica Suppl.* 3: 491-498. 1930.—A calculated concentration of 2 gm. formaldehyde per cu. m. was used with 6 strains of recently isolated pyogenic staphylococci as test objects. The practically empty room was steam heated and was kept at an average of 20.6° (18° at the lowest). The northern and eastern walls were external. In summer, when external and room temp. were nearly equal, disinfection was good. In colder mo., when temp. differences were greater than 10-15°, disinfection was very poor. Condensation of formaldehyde on the cold external walls is probably the explanation.—*B. Cohen.*

10797. **WOLTERS, K. L., und H. DEHMEL. Ueber das Kulturverfahren zum Nachweis von Tuberkelbakterien, besonders in Gesamtmilchproben.** *Zeitschr. Infektionskr. u. Hyg. Haustiere* 39(1/2): 102-114. 1931.—The sample is placed in 2 15-cc. centrifuge tubes and centrifuged at 200 r. p. m. for 15 min. The cream and supernatant milk are poured off and the sediment is shaken. To the sediment add 10 cc. of 15% HCl; close the tube with a rubber stopper and shake vigorously for 10-15 min., and again centrifuge as above. The acid is poured off, the tube inverted on filter paper, and the sediment drained. For animal inoculation the sediment is injected subcutaneously into the inner surface of the foreleg. For culture examination, the authors employ 2 tubes with 10 cc. of malachite-green-Besredka bouillon. To one of these add 1% glycerin. Through use of fluid media, the authors had in view the possible premature concentration of the organisms so that there might be an early diagnosis by microscopic examination of the sediment. Not so much acid was developed in liquid as in solid media. After 4, 6, and 8 wk. at 37° C., the supernatant fluid of the culture is removed and the sediment stained for tubercle bacilli. If there has been growth the bacteria are present in the sediment in increasing numbers. The authors report a fairly close correlation between cultural findings and animal inoculations, although they do not recommend substituting the former for the latter method. They report finding avian type tubercle bacilli in 9 of 400 examinations.—*L. D. Bushnell.*

10798. **ANONYMOUS. Instrucciones para el envio de muestras de investigación a los laboratorios biologicos. [Instructions for sending samples to biological laboratories.]** *Cuba Secret. Agric. Com. y Trab. Secc. Indust. Animal Bol.* 14. 1-31. 10 fig. 1931.—Instructions are given for securing and sending samples of blood, exudations, pus, urine, feces, cerebrospinal fluid, milk, skin, parasites, poisonous plants, tissues and organs for biopsy and autopsy, and also material concerning special diseases (rabies, tuberculosis, mastitis, etc.).

10801. **GABEL, G., und G. KIPRIANOFF. Der Gehalt an Pektinsäure und Methylalkohol im russischen Tabak.** *Biochem. Zeitschr.* 212(4/6): 337-346. 1929.—Others have shown that tobacco always contains pectin and methyl alcohol, the latter present in an easily liberated form, and during smoking for the most part absorbed from the mouth unaltered. The pectin is the mother substance from which methyl alcohol is derived. The authors found 13-20% pectic acid in cigarette tobacco, increasing as the quality decreased. In unfermented tobacco, methyl alcohol is found as a dimethyl ester, and after fermentation as a monomethyl ester of pectin. Thus comparison of methyl alcohol with pectin is a prac-

tical method for determining the progress and completion of the fermentation of cigarette tobacco. The content of methyl alcohol reaches 0.945%, about 5.5-6.4% of the pectic acid. In fermenting Russian cigarette tobacco, the content of methyl alcohol falls to 0.411-0.717%, or 2.9-3.2% of the pectic acid. The content of methyl alcohol in cigarette tobacco is 0.228-0.401%, or 1.2-2.6% of the pectic acid. In pipe tobacco, the methyl alcohol content is usually 0.074-0.158%, or 0.4-0.7% of the pectic acid. The methyl alcohol content of Machorka is 0.323%, placing this midway between pipe and cigarette tobacco. The methyl alcohol content of the various sorts of Russian tobacco falls within similar ranges, as found by Neuberg and his colleagues in tobacco from other provinces.—*H. F. Smyth.*

10802. HANZAWA, JUN, and SH. TAKEDA. On the reddening of boned codfish. *Archiv Mikrobiol.* 2(1): 1-22. 2 col. pl. 1931.—The reddened and the so-called sound salted codfish were examined chemically and microbiologically. Indol and skatol were present in small quantity, but ptomaines were absent in the reddened codfish. H_2S was not evolved from the latter, but it was seen in the so-called sound codfish. *Torula wehmeri, Micrococcus albus-translucens, M. lutulentus,* and *Bacterium zopfii* were isolated from the reddened codfish. From the so-called sound codfish, *M. albus-translucens* and a H_2S-producing *Bacillus* were isolated. Reddening of the salted codfish is caused by *T. wehmeri,* which produces red pigment on culture media. Other isolated microorganisms did not produce red color. Indol is detected in pure cultures of *T. wehmeri* and *Bact. zopfii.* Putrefaction of the salted codfish is attributed to the microorganisms mentioned. None of the organisms isolated was pathogenic to guinea pigs.—*Authors' summary.*

10805. ROBERTSON, MADGE E. A note on the cause of certain red colorations on salted hides and a comparison of the growth and survival of halophilic or salt-loving organisms and some ordinary organisms of dirt and putrefaction on media of varying salt concentrations. *Jour. Hyg.* 31(1): 84-95. 12 fig. 1931.—Experiment indicated that certain brick-red stains on salted hides are produced by growth of "halophilic" or salt-loving organisms which come from marine salt used in curing the hides. There are probably many varieties of these organisms, their common characteristic being that they flourish best in high concentrations of salt, and will not grow when the concentration falls beneath 6%. The organisms of dirt and putrefaction examined, though certain of them survived for a considerable time at a salt concentration as high as 30%, did not multiply when it was above 8%. The non-halophilic cocci examined survived at high salt concentrations much better than did the non-halophilic bacilli.

10810. BARKWORTH, H. Keeping quality of milk and the age on testing for total bacterial count. *Jour. Hyg.* 31(3): 373-374. 1931.—Tests of nearly 6000 samples of milk over a 7-yr.-period at Wye, showed an average keeping quality of 9 hrs. less for afternoon than for morning milks of the same bacterial count.

10811. BARTHEL, CHR., and E. SANDBERG. Occurrence of enzymes in press-juice of cheese. *Internat. Dairy Congr. Eng. Ed.* 1931 (Sect. 2): 46-49. 1931.—The authors examined 3 Västerbotten, 3 Emmenthal, 2 Cheddar, 1 Household, 1 Edam, 2 Limburger, 2 Stilton, 1 Roquefort, and 1 Gorgonzola cheese. Catalase was present in all except 1 Cheddar, varying between 0.0 and 106.5 cc. O. The highest values were found in moldy and in Limburger cheeses. Peroxidase was demonstrated in 7; Emmenthal and Limburger were negative. Amylase or aldehyde reductase were not demonstrated in any sample. Rennin was demonstrated in all except Emmenthal and ripe Limburger. Apart from catalase, which in this instance is derived from microorganisms, Emmenthal and Limburger cheeses contain none of the enzymes the author tried to demonstrate, whereas all the other cheeses proved to contain at least some of these enzymes.

10812. BOEKHOUT, F. W. J., en J. van BEYNUM. Roode vlekken op beschimmelde boter. [Red-spotted molded butter.] [With English summary.] *Verslag. Land. Onderzoek. Rijkslandbouwproefsta.* 36: 5-14. 3 pl. 1931.—Molded butter generally has black-green spots caused by *Cladosporium herbarum.* There sometimes also appear red spots ascribed to *Epicoccum heterochroum* (?). The latter does not form spores on the usual media,

but does so on a medium of distilled water + 2½% agar. Growth is very poor, but after 7-14 days conglomerates of blackish spores develop. Peptone (Witte) and levulose are preferred. Lactose is useful as a source of C, but fails to give so intensive a red coloring as dextrose and galactose. Heating at 48° C. for 10 min. killed the spores. This mold is more sensitive to salt than *C. herbarum*, which requires 16% of salt to inhibit growth; 11% was sufficient for the present mold. The opposite is the case with lactic acid.—*From authors' summary.*

10813. CHRISTIANSEN, M. Investigations of a factor in the milk fat with inhibiting action on the growth of pathogenic streptococci. *Internat. Dairy Congr. Eng. Ed.* 1931 (Sect. 2): 119-120. 1931.—A summary.

10814. COPELAND, LYNN, and T. M. OLSON. The bacterial flora of normal cow's udder. *So. Dakota Agric. Exp. Sta. Bull.* 218. 1-20. 1926.—Milk drawn aseptically from each quarter of 40 cows gave an average bacterial count of 1,541 per cc. Cell counts of the udders showed an average of 657,000 per cc. Bacterial and cell counts compare closely. The coefficient of correlation between bacteria and cell counts was +0.6379 + 0.03364. Lactation exerted no appreciable effect on bacterial content of the udder, nor did age of cow, except in older cows past maturity, when bacterial and cell counts greatly increased. Fore milk contained more bacteria than middle milk or strippings. Strippings contained fewer bacteria than middle milk. Colostrum, usually high in bacterial and cell content, varied considerably. Bacteria of the udder are usually gram-positive micrococci; they ferment sugar without forming gas, and may or may not liquefy gelatin. Udder cocci gave uniformly low total and volatile acidities. In some cases, curdling of the milk was accomplished by an enzyme. Digestion of the curd was noted in several instances. Milk from different cows varied in germicidal power. Cultures of bacteria artificially introduced into the udder do not survive over a few days.—*Authors' digest.*

10815. CUNNINGHAM, ANDREW. Formation of an aroma resembling that of amyl alcohol in milk. *Internat. Dairy Congr. Eng. Ed.* 1931 (Sect. 2): 1-5. 1931.—Development of this aroma was associated with growth of white and orange micrococci. The taint was observed when cows were housed, but disappeared when they were put out to grass. Evidence supported the view that the source of these micrococci was the floor of the byre.—*Author's summary.*

10816. DEMETER, KARL J. The influence of catadyne silver on the microflora of milk. *Internat. Dairy Congr. Eng. Ed.* 1931 (Sect. 2): 118-119. 1931.—Summary of a preliminary report.

10817. DORNER, W. The reliability of Burri's spreading method for counts of microorganisms in milk and its limitations. *Internat. Dairy Congr. Eng. Ed.* 1931 (Sect. 2): 44. 1931.—A summary.

10818. GORINI, COSTANTINO. On the work performed to promote a hygienic milk production in various countries. Preliminary report. *Internat. Dairy Congr. Eng. Ed.* 1931 (Sect. 2): 58-59. 1931.—A summary.

10819. GRIMES, M. Microbiological analysis of butter in relation to flavor score. *Internat. Dairy Congr. Eng. Ed.* 1931 (Sect. 2): 5-10. 1931.—135 samples of butter graded as excellent (5), good (70), fair (53), and bad (7), were examined for acidity, total bacterial count, liquefying bacteria, yeasts and molds. No correlation was found between results of microbiological analysis of butter and flavor score of butter 2 weeks old.—*From author's summary.*

10820. HANSEN, A. P., and JOHS. JENSEN. Studies of development of volatile acids in the use of starters. *Internat. Dairy Congr. Eng. Ed.* 1931 (Sect. 2): 60-71. 1931.—The work confirmed earlier findings that starters contain, besides true lactic acid bacteria, those producing aroma, and characterized mainly by production of CO_2 and other volatile acids, especially acetic. The ability of the "aroma" forms to produce volatile acids is markedly enhanced when in symbiosis with lactic acid bacteria. This production took place evenly throughout fermentation. The curve resembles the acidity curve, but apparently the maximum production of lactic acid and of the volatile acids (determined by distillation) is reached earlier than the maximum CO_2 content. If production of volatile acid is connected with development of aroma, it seems that there is no particular advantage in using especially high or low temp. in acidifying, as high temp. at the same acidity does not enhance production of volatile acids more than a temp. around 20° C.; and very low temp. has not been proved to give the aroma bacteria more favorable conditions.—*From authors' summary.*

10821. HENNEBERG. Spoilage organisms in milk, butter, and cheese, most common in Germany. *Internat. Dairy Congr. Eng. Ed.* 1931 (Sect. 2): 87. 1931.—A summary.

10822. HOOD, E. G., and A. H. WHITE. An a-typical Escherichia coli producing bitter milk. *Internat. Dairy Congr. Eng. Ed.* 1931 (Sect. 2): 19-24. 1931.—Pure cultures inoculated into sterile milk produced typical bitterness in 24 hrs. at 25° C. The organism exhibited minor differences from *E. coli* in its behavior in milk, lack of indol production, and in its failure to produce acid and gas in raffinose, dulcite, and dextrin. Morphology and cultural and physiological characteristics are described.

10823. HOSTETTLER, H. Analytical determinations of the gases in cheese. *Internat. Dairy Congr. Eng. Ed.* 1931 (Sect. 2): 127-128. 1931.—A summary.

10824. IWANOWSKI, WACLAW. Experiments with regulation of cheese mellowing by alteration of the conditions of unrestricted air-supply. *Internat. Dairy Congr. Eng. Ed.* 1931 (Sect. 2): 94-95. 1931.—A summary.

10825. KLIMMER, M. Bietet der Anschluss der Vorzugsmilchbestände an das freiwillige Tuberkulosetilgungsverfahren genügend Sicherheit dafür, dass die Vorzugsmilch frei von Tuberkelbazillen ist, und wie kann das genannte Verfahren ergänzt oder ersetzt werden, damit die Förderung des Freiseins der Vorzugsmilch von Tuberkelbazillen erfüllt wird? [With discussion by **H. RAUTMAN** and reply by **M. KLIMMER.**] *Tierärztl. Rundschau* 37 (42): 737-746. 1931.—It is concluded from laboratory studies that certified milk can be guaranteed free from tubercle bacilli only if the cows are free from tuberculosis. Diagnosis failures in clinical bacteriological studies are considerable.—*From author's summary (transl.).*

10826. KOESTLER, G., und H. HOSTETTLER. Untersuchungen über die Natur des bei sog. "Nachgärungen" im Emmentalerkäse auftretenden Gases. *Landw. Jahrb. Schweiz* 45 (4): 446-465. 7 fig. 1931.—Gas from eyes of Swiss cheese during the main fermentation normally contains less than 1% of H. Gas arising during the "after" fermentation does not differ essentially from the former, and it is concluded that it is due to a recurrence of propionic acid fermentation. It is not a question of avoiding contamination, but of avoiding a recurrence of the same factors which caused the main fermentation.—*From authors' summary (transl.).*

10827. KRAMER, Y. M. Experiences in the systematic improvement of milk hygiene in Holland. *Internat. Dairy Congr. Eng. Ed.* 1931 (Sect. 2): 45. 1931.—A summary.

10828. KRENN, JOSEF. The value of the measurements of the conductivity of milk to its chemical and hygienic testing. *Internat. Dairy Congr. Eng. Ed.* 1931 (Sect. 2): 93. 1931.—A summary.

10831. RÜDIGER. Konservierung von Milch für die Untersuchung. *Zeitschr. Untersuch. Lebensmittel* 62 (1/2): 198-202. 1931.—For preserving milk for testing, 0.07% paraformaldehyde solution proved best.

10832. RUMMENT, JULIUS. Dairy water and the keeping quality of butter. *Internat. Dairy Congr. Eng. Ed.* 1931 (Sect. 3) : 97. 1931.—A summary.

10833. SEELEMANN, M. Massnahmen zur hygienischen Qualitätsverbesserung der Milch. [Hygienic measures for improving the quality of milk.] *Milchwirtschaftliche Zeitfragen* 1. 69-88. M. & H. Schaper: Hannover, 1931.—A review.

10834. SKAR, OLAV. The reductase examination. *Internat. Dairy Congr. Eng. Ed.* 1931 (Sect. 2) : 87-88. 1931.—A summary of experimental results with this test for bacterial contamination of milk.

10835. STABLER, SALLY HAMILTON. The electrical process of milk pasteurization. *Amer. Jour. Hyg.* 14 (2) : 433-452. 1 fig. 1931.—Experiments indicated that electrical pasteurization at 73° C. is as efficient, both in reduction of bacterial count and in kinds of organisms destroyed, as the commercial holding method at 62°; and that, at 62°, while it destroys the same kinds of organisms, it does not reduce the bacterial count of milk to so great an extent as the commercial holding method at 62°. It diminishes the rate at which cream rises, so that the milk seems to have more cream after 24 hrs., whereas the holding method increases this rate. Both kinds of pasteurization result in milk showing the same cream volume after 144 hours.—*Author's summary.*

10836. STARK, C. N. The source of ropy milk bacteria in nature. *Papers & Proc. Ann. Conv. New York State Assoc. Dairy & Milk Inspectors* 8: 56-57. 1930.—The author reports studies of 7 types of bacteria causing ropiness, isolated from raw and pasteurized milk and from places in and around dairy barns. Of about 500 isolations studied, at least 75% were gram-negative rods producing acid and gas in lactose broth. More than 100 samples of feeds showed alfalfa hay, clover hay, chaff, soy bean meal and cottonseed meal to contain thousands of ropy-milk bacteria per gm.; other feeds examined contained small numbers or none.

10837. STARK, C. N. Some observations in the bacterial control of pasteurized milk. *Papers & Proc. Ann. Conv. New York State Assoc. Dairy & Milk Inspectors* 8: 58-60. 1930.—Bacterial counts (standard agar plate method) on all raw milk delivered to a number of milk plants in Ithaca, New York, and vicinity, showed 60-85% to contain less than 30,000 bacteria per cc. On the basis of numbers of bacteria surviving heat treatment, the holder method of pasteurizing milk was more efficient than the electropure process.

10838. VAN SLYKE, L. L. The chemistry of sour milk. *New York State [Geneva] Exp. Sta. Tech. Bull.* 140. 14p. 1928.—A review of previously published work of Van Slyke and associates on problems dealing with souring of milk. The author discusses lactic acid formation and its reaction with other milk constituents, particularly the calcium phosphates and caseinates. Usually less than 20% of the lactic acid formed is found in the free state. The first perceptible flavor characteristic of souring milk is not due to lactic acid or to a change in pH, but to some volatile substance.—*J. R. Haag.*

10842. VIRTANEN, ARTTURI J. The proteolytic enzymes of the lactic acid bacteria and the mellowing of cheese. *Internat. Dairy Congr. Eng. Ed.* 1931 (Sect. 2) : 128-129. 1931.—A summary.

10843. WILLIAMS, R. STENHOUSE. The importance of a complete study of nutritional value of milk. *Internat. Dairy Congr. Eng. Ed.* 1931 (Sect. 2) : 109-118. 1931.—A critical review of published work on changes in milk when heated, and discussion of their possible importance to human nutrition.

BACTERIOLOGY AND OTHER MICROBIOLOGY

SOIL

H. J. CONN, *Editor*

(See also in this issue Entries 10733, 10770, 10871, 11482)

10844. BAUMGÄRTEL, TRAUGOTT. Zur Kultur von Bodenprotozoen. *Arch. Protistenk.* 70 (2) : 491-496. 3 fig. 1930.—The difficulties usually encountered in culturing soil protozoa are avoided by growing *Azotobacter chroococcum* Beijerinck according to the method recommended by Beijerinck. Soil protozoa are found actively feeding on the bacteria in the surface film of the culture. Addition of $(NH_4)_2SO_4$ to the media results in gas formation, which breaks up the membrane, while K_2SO_4 favors surface membrane formation. Particularly good cultures can be made from soils which have been fertilized with K. The method offers a rapid means of gaining a glimpse of the biological characteristics of the soil and also may be modified for the pure culture of protozoa.—*G. W. Goldsmith.*

10845. BAZAREWSKI, STEFAN. Badania nad bakteroidami. [Bacteroids.] [With French summary.] *Roczniki Nauk i Leśnych (Polish Agric. & Forest. Ann.)* 17 (1/2) : 1-34. 1927.—Acidity of medium and presence of purine bases strongly influence transformation of rods of nodule bacteria into bacteroids, the structure of which does not indicate an organization superior to that of the rods. Generally the bacteroids do not multiply, but sometimes very young bacteroids are transformed into simple bacteria. The bacteria of the nodules can fix considerable quantities of free N when in artificial media, during the active multiplication of the cells. The albuminous substance produced in cultures of nodule bacteria is not the result of N fixation. Bacteroids are involution forms incapable of multiplying and probably they can not fix free N.—*Author's summary (transl.).*

10846. BURK, DEAN, and HANS LINEWEAVER. The influence of calcium and strontium upon the catalysis of nitrogen fixation by Azotobacter. *Archiv Mikrobiol.* 2 (1) : 155-186. 5 fig. 1931.—The chemical mechanism of N fixation by *Azotobacter* requires either Ca or Sr in relatively large concentrations, 25-50 p.p.m. in the customary culture medium giving normal rates of fixation in 2-day cultures, and 1-5 p.p.m. giving relatively inappreciable rates of fixation. All soluble non-toxic Ca compounds (about 16) and all Sr compounds (about 8) investigated are suitable sources. Ca and Sr can not be replaced by other elements, some 50 having been tested with entirely negative results. It is shown from 5 sources of evidence that Ca and Sr exert their effect per se, and not by virtue of any contained impurity. Ca and Sr are not required for normal growth of *Azotobacter* in fixed N, providing certain other elements, such as Mg, Ba, or Gl, are present in sufficient concentration. The effect of Ca and Sr on N fixation may be shown, under suitable conditions, i.e., with Ca-starved cells, to be exerted immediately on addition to the culture medium. i.e., within 30-60 min. On the other hand, with Ca-rich cells, the effect of suddenly decreasing the Ca-concentration in the medium is not prominent until after a number of hrs. In free N, *Azotobacter* shows to a marked extent a phenomenon often presented by other organisms, namely, rate of growth is

markedly dependent on concentration of organisms, due, in *Azotobacter*, to the fact that when fixing N the ratio, concentration of organisms: concentration of Ca in the medium, is very important. In fixed N, the effect of concentration of organisms on rate of growth is normally not observed. No understanding has been reached as to the nature of the effect of Ca and Sr, except that it is exerted inside and not outside the cell. There are indications that the relatively large concentrations of Ca are not very efficiently employed directly in fixation, but that a great proportion of the Ca is diverted to ordinary metabolic purposes. This would imply that the Ca used directly in fixation, being actually of very small amount, is truly catalytic, and not directly concerned merely in phenomena of antagonism, solubility effects, etc.—*From authors' summary.*

10847. CORBET, A. S. A bacteriological study of the decomposition of soil organic matter and its bearing on the question of manuring. *Jour. Rubber Res. Inst. Malaya* 3 (1) : 5-27. 9 fig. 1931.—The low bacterial population of Malayan soils renders the plate count method unsuitable for comparing their biological activities, and hence the fertilities of different soils; moreover, accurate values can not be expected of this method where only a proportion of the total organisms present are cultivated. Such accurate values, however, can be obtained from a method described, entailing estimation of the CO_2 yield of soils in the laboratory. This method depends on the fact that after an initial transitory period, the equation, $y=Ft^m$ is followed, where y is the yield of CO_2 in time t, and F and m are constants. This formula has been investigated through observation of glucose fermentation by a single organism. The constant F (fertility constant) is concluded to be a measure of the daily yield of CO_2 by any given soil in the field. As yet the constant m has not been fully interpreted, but it represents a retardation in rate of gas evolution. Manuring of rubber by chemical fertilisers is generally connected with the effects on soil microorganisms. By the CO_2 method, the effect of different fertilisers on soil fertility can be assessed, and hence the type and quantity of fertiliser required to increase biological activity on any given soil can be determined.—*Author's summary.*

10848. DEMOLON, A., et G. BARBIER. Influence de la constitution physique des sols sur l'allure des phénomènes microbiens dont ils sont le siège. *Ann. Agron.* [*Paris*] 1 (4) : 531-535. 1931.—The struggle between soil and microorganisms for soil water is influenced by mineral colloids (clay) which affect the mobility of the organisms (adsorption) and the diffusion of their secretions and soluble products. Sandy soils are more like liquid media and present a large surface to the air; clay soils behave more like solid media. This explains the irregular distribution of nitrates and H-ions at neighboring points in an apparently homogeneous section, the activation of biological processes by tillage, and the difficulty experienced at times in soil inoculations.—*From authors' summary (transl.).*

10849. FEHÉR, DÁNIEL. Vizsgálatok az Erdötalaj N-Anyagcseréjéröl. [N metabolism of forest soils.] [With German abridgement.] *Mat. és Természettud. Értesitö (Math. u. Naturwiss. Anz. Ungarischen Akad. Wiss.)* [*Budapest*] 46: 171-200. 1 pl. 1929.

10850. FEHÉR, DÁNIEL. Vizsgálatok az Erdötalaj biológiai Tevékenységének Idöszaki Változásairól. [Sequence of bacterial life in forest soils.] [With German summary.] *Mat. es Természettud. Értesitö (Math. u. Naturwiss. Anz. Ungarischen Akad. Wiss.)* [*Budapest*] 46: 201-234. 1929.

10851. ITANO, ARAO, and SATIYO ARAKAWA. Investigation on Winogradsky's Azotobacter test as to its applicability to some rice-field soils in Japan. *Ber. Ohara Inst. Landw. Forsch.* 4 (3) : 365-369. 2 pl. 1930.—The Azotobacter test was applied to 9 different soils from rice fields of known productivity. As a whole, no agreement between productivity and results of the test was reached. This is probably due to the acidity, which is generally high in rice fields where good crops are obtained even at pH 4.0; *Azotobacter* growth is very limited at such acidity.—*A. Itano.*

10852. ITANO, ARAO, and SATIYO ARAKAWA. Investigation on cellulose decomposition in soils. 1. Re-examination of some stock cultures. *Bull. Agric. Chem. Soc. Japan* 7 (4/8) : 42. 1931.—*Cellulomonas* produces enzymatic zones on cellulose agar medium. The kind of medium plays an important rôle and organic N is the best source of N, especially digested casein and yeast extract. All cultures retained their activity after yrs. of storage, although *C. uda, C. fima,* and *C. gelida* manifested more ability to decompose cellulose than *C. cellasea.*—*Authors' conclusions.*

10853. KOFFMAN, M. De egentliga jordprotozoerna. Deras ställning till andra jordmikroorganismer och deras roll vid de mikrobiologiska processerna i jorden. [The true soil protozoa. Their relation to other soil microorganisms and the part they play in the microbiological processes of the soil.] [With English summary.] *Meddel. Centralanst. Försöksväs. Jordbruksområdet* 391. 1-67. 3 pl. 1931.—Protozoa exist in normal soil, but they form an insignificant part of the micropopulation in regard to number, species, and volume. Thus true soil protozoa would not seem to exercise any appreciable effect in normal soil on the number of bacteria or on other soil microorganisms. Figures relating to the abundance of species and individuals in a soil of normal moisture content must depend on application of indirect methods, in which there takes place a development of cysts of aquatic protozoa that do not belong to the active inhabitants of the soil. Direct study of the metabolism of the soil under various physiological conditions and normal moisture content confirmed the view that the microfauna of the soil exercises but an insignificant influence on the microbiological processes in the soil. Finally, vegetation experiments have also shown that the improvement in soil fertility following sterilization of the soil is due, not to the killing of the protozoa, but to other factors. This does not exclude the possibility that in abnormal conditions, e.g., in waterlogged soil or soil irrigated with sewage, as also in the use of artificial substrates, results may be attained indicating that protozoa check the development of bacteria and are important for metabolism. From both theoretical and practical points of view, however, this is of minor importance in its bearing on the problems connected with the true soil protozoa and the fertility of normal soil.—*Author's summary.*

10854. THORNTON, H. G. Lucerne "inoculation" and the factors affecting its success. *Great Brit. Imp. Bur. Soil. Sci. Tech. Commun.* 20. 1-39. 12 fig. (2 maps). 1931. —A review of the problem is followed by a discussion of results in Great Britain, Canada, South Africa, New Zealand and Australia.

10855. VERONA, O., et G. LUCHETTI. La dissolution du phosphore par l'effet de l'activité des microbes de la "ryzosphère." *Soc. Internaz. Microbiol. Boll. Sez. Ital.* 3 (6) : 201-203. 1931.—Studies were made of the numbers of microorganisms in soils on which a legume (bean), a grain crop (corn), or a cruciferous crop (*Diplotaxis erucoides* or false rocket) had been grown for 3 yrs., and of the influence of the organisms in these soils on production of available P from tricalcium phosphate in solution cultures. The greatest numbers of organisms developing on bean agar were found in soil under the legume; the smallest numbers, in soil under the crucifer. After 10 days in the culture tests, there was the greatest production of soluble P by the legume soil; but after 20 days, soil from the area on which crucifers had been grown showed the greatest effect. This is believed to be correlated with the greater ability of crucifers to utilize the P from tricalcium phosphate.—*P. E. Brown.*

10856. WAKSMAN, SELMAN A., and ROBERT L. STARKEY. The soil and the microbe. An introduction to the study of the microscopic population of the soil and its rôle in soil processes and plant growth. xl + 260p. 85 fig. John Wiley & Sons: New York; Chapman and

Hall: London, 1931.—The following are the chapter headings: The soil and the plant; The microbe and its activities; The soil population and its distribution; Rôle of microbes in the decomposition of organic substances in the soil; Transformation of nitrogen by soil microbes; Transformation of mineral substances in soil through the direct or indirect action of microorganisms; Interrelationships between higher plants and soil microorganisms; Modification of the soil population; Importance of microbes in soil fertility. This is an introductory treatment of the subject, in which are discussed the organisms comprising the soil population, factors affecting their development, relationships of these microorganisms to decomposition of organic materials, formation of soil organic matter, changes of mineral substances in soils, and the relationships of microorganisms to plant development. A limited list of selected references is given at the end of each chapter. The volume is intended to suit the needs of students with some chemical and biological background, who are commencing the study of soil microbiology. It should serve a useful purpose for more advanced students who wish a brief survey of the field.—*R. L. Starkey.*

10857. ZIEMIĘCKA, JADWIGA. Rozkład pentozanów przez mikroorganizmy gleby. Studja nad mikrobiologia gleby, cz. V. [Destruction of pentosans by microorganisms.] [With French summary.] *Roczniki Nauk i Leśnych (Polish Agric. & Forest Ann.)* 25(2/3): 313-332. 5 fig. 1931.—From soils, straw, and manure was isolated by the direct method a homogeneous group of bacilli which can attack xylan in an aerobic and non-acid medium. This species, *Bacillus* **xylanophagus*** (p. 320), is a rod 1 × 3-5 μ. It is motile, with rounded ends when young, and forms terminal or subterminal spores, during which time the cell is often swollen as in *Clostridium pasteurianum*. It is strictly aerobic, needs mineral N, reduces nitrates, forms granulose in media with xylan and pentoses, grows somewhat on hexoses, starch and peptone, but not on cellulose. Optimum temp. is 28-30° C. It is most frequent in plant residues. Both pure and impure cultures actively decompose xylan. The ratio between xylan decomposed and mineral N assimilated or liberated is 100: 3-5. Furthermore, xylan as such is not an accessible source of energy for free N fixation.—*Author's summary (transl.).*

GENERAL BACTERIOLOGY

R. E. BUCHANAN, *Editor*

10858. ANDERSON, J. S., F. C. HAPPOLD, J. W. McLEOD, and J. G. THOMSON. On the existence of two forms of diphtheria bacillus—B. diphtheriae gravis and B. diphtheriae mitis—and a new medium for their differentiation and for the bacteriological diagnosis of diphtheria. *Jour. Path. and Bact.* 34(5): 667-681. 1 col. pl. 1931.—There exist 2 well-defined forms of the diphtheria bacillus, at least as distinct as the typhoid and paratyphoid bacilli. To these it is proposed to give the names *B. diphtheriae* f. gravis (p. 669) and *B. diphtheriae* f. mitis (p. 670). The former has a flat colony, lacking lustre and with spreading irregular margin; it grows in bouillon with pellicle and granular deposit, and actively ferments polysaccharides, dextrin, starch and glycogen. It is associated with the more severe and toxic cases of diphtheria, which are difficult to control by serum. The latter has a rounded, shining colony with irregular margin; it grows in broth with uniform turbidity and fails to ferment starch and glycogen. It is associated with the milder cases of diphtheria, more easily controlled by serum, and is probably chiefly dangerous through causing laryngeal obstruction. There is a smaller group of intermediate forms to which the Park-Williams 8 strains belong. A blood agar medium is described, prepared with slightly-heated broth sterilized by filtration, and containing 0.04% K tellurite, which permits determination of the presence or absence of *B. diphtheriae* at sight in 90% of cultures from throat swabs after 18-24 hrs. incubation. It also gives, with the gravest types of diphtheria—those associated with *B. diphtheriae gravis*, a picture so characteristic that it is not likely to be confused with anything else.—*J. W. McLeod.*

10859. ANDERSON, LUCILE R. A study of bacilli of the genus Hemophilus with regard to the X- and V-growth factors under aerobic and anaerobic conditions. *Amer. Jour. Hyg.* 13(1): 164-200. 1931.—Study of 6 strains of *Bacillus influenzae* indicates that both X- and V-factors are required, under aerobic conditions for both hemolytic and non-hemolytic strains. The 4 types of hemophilic bacilli studied do not require the X-factor for growth under anaerobic conditions, but do require the V-factor. Judging from cultural reactions, influenza bacilli carry on a normal existence in media containing only the V-factor, under anaerobic conditions. None of 13 anaerobes tested reacted positively to the benzidine test for peroxidase; of 44 aerobes tested, all but 4 strains, 2 of which were streptococci, gave a positive reaction. *B. influenzae,* hemolytic and non-hemolytic, and *Hemophilus canis* do not produce peroxidase. *Bacillus para-influenzae* produces peroxidase under both aerobic and anaerobic conditions. Banana reacts positively to the benzidine test for peroxidase. All evidence appears to substantiate Fildes' view that the X-factor is associated and identical with peroxidase. Evidence is submitted supporting the idea of Davis that there is interaction of the X- and V-factors.

10860. ANDERSON, R. J., and E. GILMAN ROBERTS. Concerning the carbohydrates associated with the ether-soluble lipoids of tubercle bacilli. *Amer. Rev. Tuberc.* 22(6): 664-668. 1930.—The phosphatide from the avian tubercle bacillus yielded about 47% water-soluble material, determined as Ba glycerophosphate, mannose phenylhydrazone, inositol, and glucosazone. The phosphatide of the bovine bacillus (which, unlike the avian phosphatide, was very stable and hydrolyzed with great difficulty) yielded about the same % of water-soluble constituents as the foregoing, determined as mannose phenylhydrazone, inositol and other as yet unidentified carbohydrates. The purified wax from the human bacillus yielded nearly 40% water-soluble material as glycerophosphoric acid, reducing sugars giving pentose color reactions and including *d*-arabinose, other as yet unidentified carbohydrates, and glucosamine insufficient in amount to account for the N present in this as in other phosphatides examined. In none of the phosphatides was any nitrogenous base found. The authors emphasize the great complexity of the compounds formed by these organisms, and suggest that the carbohydrates associated with the lipoid fractions may form the important link by means of which the fatty acids are combined in the molecules of these compounds, in which case the bacillary lipoids would represent new types of chemically and biologically interesting chemical compounds.

10861. ANDRESEN, P. H., et REIDAR SCHROEDER. Recherches sur la formation d'acide dans une culture du bacille de la diphtérie. *Acta Path. et Microbiol. Scandinavica, Suppl.* 3: 41-51. 1930.—The authors corroborate the finding that diphtheria bacilli can produce acid in a carbohydrate-free medium and that acid production is dependent partially on amount of O present. They distinguished, in general, 3 types of organisms

designated by Spronck as: (a) those cultures which form acid and remain acid; (b) those which become alkaline; and (c) those which form acid and then become alkaline. Reaction of individual culture depends on experimental conditions.—*L. Baumgartner.*

10862. **ASCHNER, MANFRED. Die Bakterienflora der Pupiparen (Diptera). Eine Symbiosestudie an blutsaugenden Insekten.** *Zeitschr. Wiss. Biol. Abt. A. Zeitschr. Morph. u. Ökol. Tiere* 20(2/3): 368-442. 5 pl., 5 fig. 1931.—The relationship between 10 species of Diptera and the bacteria and rickettsias inhabiting them, are studied by means of bacteriological staining methods and in-vitro cultures. The latter gave negative results, except for certain extracellular rickettsias. Histological and morphological characteristics are given in detail. The inhabitants of each dipteran species are morphologically distinguishable. All organisms resembling *Rickettsia melophagi* morphologically are considered rickettsias. Infection of the larvae from the parent is found to take place through the secretions of the nutritive glands rather than through invasion of the ovaries, except in the case of certain intracellular rickettsias. The author considers the insect-microorganism relationship to be symbiotic rather than host-parasitic. Larvae of *Stegomyia fasciata*, fed on sterile blood from suitable hosts, were unable to complete their development except when bacterial culture of filtrate was added. A literature list of 42 titles is cited.—*L. M. Dickerson.*

10863. **BAKER, FRANK. Preliminary note on the rôle of coccoid micro-organisms in the disintegration of cell-wall substances.** *Zentralbl. Bakt. II. Abt.* 84(19/22): 452-454. 3 pl. (2 col.) 1931.

10864. **BARTELS, HENRY A. Outline of bacteriology.** 128p. 47 illus. Wm. Albert Broder: New York, 1929. Price $2.

10865. **[BEZSONOVA, A. A., and M. G. LOKHOV.] БЕЗСОНОВА, А. А., и М. Г. ЛОХОВ. Пигментообразование у чумной палочки. (A case of pigment production by plague bacilli.)** Вестник Микробиологии, Эпидемиологии и Паразитологии (*Rev. Microbiol., Épidémiol. et Parasitol.*) 9(1): 109-112; English summary, 137. 1930.—In the Kalmyck region, during a plague epizootic (1929), a culture from the blood of a dead marmot, after 2 mo. on agar, gave several large wrinkled colonies of R type, which became dark violet in the center (secondary colony). With the exception of the pigmented ones, colonies lost their viability; plantings from pigmented colonies grew but were without pigment. Pigmented cultures gave a positive agglutination reaction with anti-plague serum. Smears were typical for plague, but guinea pigs infected with these cultures survived. This strain differed from that described by Preisz, in that it was formed from a culture obtained freshly from a marmot, and also in that the pigmented culture was morphologically atypical.—*G. A. Lebedeff.*

10866. **COUDRAY, GEORGES. Contribution à l'étude de la coloration de Gram. Étude critique de la coloration de Gram. Essai sur la modification de Gottstein. Essai de stabilisation de la solution colorante de violet de gentiane phénique.** 104p. Berger-Levrault: Nancy, 1929.—This thesis, presented at the University of Nancy, is divided into 2 sections, the 1st containing a critical discussion of the Gram stain; the 2nd, the writer's personal investigations. Pt. I is fairly detailed, discussing the history of the technic, various factors to be controlled in carrying out the procedure, principal modifications of the Gram stain (omitting American work, however), and theories of the reaction involved. In the 2nd part, results of 2 main lines of investigation are discussed. One of these was to determine whether different kinds of bacteria can be distinguished by the speed of decolorization in the Gram technic; no marked success was obtained. The 2nd line of investigation was an attempt to make the carbol gentian violet more stable by addition of various chemicals designed to prevent precipitation. In this also the writer was unsuccessful. —*H. J. Conn.*

10867. **CUNNINGHAM, ANDREW. The life-cycle of B. saccharobutyricus von Klecki. III. The slender rod phase and secondary transformations.** *Zentralbl. Bakt. II. Abt.* 83(1/7): 1-21. 1 pl. 1931.—The morphological, cultural and biochemical characteristics of the slender rods obtained from cultures of *B. saccharobutyricus* and the characterisation of the various types are discussed. The slender rods include strains identical with *B. circulans* Jordan, *Pectinobacter amylophilum* Makrinov, *B. brevis* Migula, *B. globigii* Migula, *B. putrificus* Bienstock, *B. sporogenes* Metchnikoff, and *Clostridium putrificum* as described by Reddish and Rettger. The controlled experiments in which the slender rods were secured from cultures of *B. saccharobutyricus* (primary transformations) are described, and experiments in which cultures of the large rods (other than *B. saccharobutyricus*), cocci, short rods and slender rods described in these papers yielded other forms included in these groups (secondary transformations), are summarised. A slow decomposition of cellulose was observed when tubes of Omelianski's mineral-salt-filter-paper medium were inoculated with whole potato cultures of the *Pectinobacter amylophilum* type, and incubated anaerobically.—*A. Cunningham.*

10868. **CUNNINGHAM, ANDREW. The life-cycle of B. saccharobutyricus von Klecki. IV. Special morphology and methods of reproduction.** *Zentralbl. Bakt. II. Abt.* 83(1/7): 22-32. 5 pl. 1931.—Detailed studies indicate that, in addition to multiplying by binary fission, *B. saccharobutyricus* is capable of producing specialized reproductive organs. In certain cells (gonid angia)—which may be similar in size and shape to the normal vegetative cells of the organism or may be of an enlarged spherical, pear-shaped or spindle-shaped type—gonidia may be formed. The latter may appear as minute, intensely-stained granules or as larger bodies not colored by weak stains. Both types escape from the gonidangia when these undergo dissolution, but they may also be liberated by budding. The free gonidia are actively motile and many are so minute that their presence can only just be detected when cultures are examined at the usual magnifications. Gonidia are capable of multiplying by fission and in a few cases they have been grown in pure culture. In such instances they formed, on solid media, a delicate scarcely visible growth, similar in character to the dwarfed growths of Löhnis and Smith. Gonidia have been observed to grow into regenerative bodies—spherical cells about the size of ordinary micrococci. They may also produce rods. When gonidia grow into rods while still within the gonidangia, branched forms are produced. In certain cases gonidia are capable of developing into spores within the gonidangia; in this way endospores are formed. However, when gonidia attached to rod-shaped cells as buds develop into spores, exospores are produced. Microcysts have been observed, and appearances similar to those referred to by Löhnis and Smith as indicating conjunction and regeneration from the symplasm have also been seen. The mechanisms of the transformations referred to in parts 2 and 3 are discussed.—*A. Cunningham.*

10869. **CUNNINGHAM, ANDREW. The life-cycle of B. saccharobutyricus von Klecki. V. Confirmatory evidence.** *Zentralbl. Bakt. II. Abt.* 83(8/14): 219-232. 1931. —The author presents the results of studies made on cultures, obtained from various type culture collections, of strains similar to those secured from *B. saccharobutyricus*. In certain cases the cultures proved to be distinct from those originally deposited in the collections, but similar to certain of the other forms cultivated from *B. saccharobutyricus*, and so furnished important evidence in support of the conclusions already arrived at. A study of the literature also showed that certain of the observations made in the investigation receive support from results of previous workers. In a general discussion of results, attention is drawn to the facts that the observed changes in morphological and cultural characteristics almost all took place during 3 short periods; that, when first isolated, the new types

were often extremely unstable; and that certain of them occur comparatively rarely in nature. These facts support the view that the changes observed are in reality transformations. It is also pointed out that the author's results exhibit a striking general similarity to those obtained by Löhnis and Smith on *Azotobacter* and by Haag on *B. anthracis*.—*A. Cunningham.*

10870. GUNDEL, M. Das biologische System der Streptokokken. *Zentralbl. Bakt. I. Abt. Orig.* 115(1/2): 44-66. 1929.—The author divides streptococci into 7 sections, on the basis of action on blood agar and other media: (1) The green-producing streptococci of the oral cavity, giving their relation to viridans and lactic acid streptococci, and to enterococci; and their pathogenic significance. (2) *Streptococcus lanceolatus* (pneumococcus) in its relation to the mouth and lactic acid streptococci, and to the enterococci, with a contribution to its diagnosis. (3) The enterococci. These are divided into 2 types on the basis of differences in growth on agar and in aesculin media, in thermolability, and in ability to ferment raffinose. (4) The viridans streptococci. Under this section he classes those occurring as etiologic agent in endocarditis lenta. They are closely related to Type A enterococcus. This organism is recognized as the true viridans streptococcus. The principal differences between viridans streptococci and Type A enterococcus consist in the pathogenicity of the former for mice and in the absence of fermentation of raffinose. (5) The lactic acid streptococci. These are differentiated from the other green-producing forms by their reaction in litmus milk and by their thermostability. (6) Transitional forms. These could not be classified satisfactorily. The author gives the following division of the streptococci into groups: Group A. Stable races: I. *Strep. pyogenes haemolyticus;* II. *Strep. viridans;* III. *Strep. lanceolatus* (pneumococcus); IV. Obligate anaerobic streptococci. Group B. Labile races: I (V). Pleomorphic streptococci—(a) mouth streptococci, (b) enterococci Types A and B, (c) milk streptococci (Type A, *Strep. lactis;* Type B, *Strep. acidi lactici*); II (VI). The group of anhemolytic streptococci. 7. Differential diagnoses of the streptococci are given, the differential characters being tabulated.—*D. H. Bergey.*

10871. JENSEN, H. L. The genus Micromonospora Örskov, a little known group of soil microorganisms. *Proc. Linn. Soc. N. S. Wales* 55(3): 231-248 1 pl. 1930.—10 strains (designated by number) of the *Streptothrix chalcea* type from soil, were studied in culture; morphology, cultural relationships, O requirements, temp. relationships, heat resistance, resistance to various dyes and to acidity, and ability to utilize various N compounds and to decompose cellulose being reported in detail. The evidence justifies entirely the establishment of this group of microorganisms as a separate genus *Micromonospora,* as suggested by Orskov. Their vegetative thallus is composed of long, delicate, branching hyphae. The mode of spore formation resembles the formation of bacterial ectogonidia: short lateral branches sprout from the main hyphae, each bearing a single terminal spore, oval to spherical, highly refractive, and staining deeply with anilin dyes and haematoxylin. Spores and mycelium are gram-positive, but not acid-fast. Spores show a somewhat higher thermo-resistance than vegetative hyphae. The organisms are strictly aerobic, mesophilic, and very sensitive to acidity and to organic dyes. Their proteolytic and diastatic activities are rather weak. Free N is not fixed; some strains reduce nitrate to nitrite. Cellulose is decomposed actively by several strains They may occur in considerable numbers in the soil, occupying 5-8% of the total numbers of colonies of Actinomyces type. Their abundance seems to be increased by addition of cellulose or lignin to the soil. The author refers to this genus (but does not formally publish the new comb.), the organism isolated by Williams from pericarditic exudate (*Jour. Med. Res.* 27: 157-161. 1912).

10872. KUHN, J. Príspevek k biologii, pathogenite a serologiisvítících bakterií. [Biology, virulence and serology of photogenic bacteria.] *Biol. Spisy Vysoké Skoly Zverolékarské Brno (Publ. Biol. École Véter.* 6: (137-143). 1927.—The phosphorescence of photogenic bacteria was diminished or completely lost by passage through mice, but was greatly increased by passage through frogs, for which the strains studied possessed a high degree of virulence. The strains were non-pathogenic for white mice, rats, guinea pigs or rabbits. Precipitating and agglutinating serum is easily produced in rabbits, following injections of the organisms.—*L. C. Havens.*

10873. MacLEOD, [J. W.] Variations in the periods of exposure to air and oxygen necessary to kill anaerobic bacteria and their bearing on the theory that the oxygen intolerance of anaerobes is due to peroxide formation. *Acta Path. et Microbiol. Scandinavica Suppl.* 3. 255-267. 1930.—It has been shown recently that, in bacteriological media exposed to O, oxidation-reduction potentials are developed more positively than is compatible with the growth of anaerobic bacteria. The explanation that H_2O_2 formation by the bacteria is a factor in anaerobiosis has therefore been considered superfluous. Those who adopt this point of view have failed to realize that the phenomenon of anaerobiosis includes the rapid death of anaerobic bacteria in the presence of O, as well as their inability to grow. It has been found that when care is taken to eliminate sporing forms by using very young cultures, the period of free exposure to O compatible with continued life of anaerobic bacteria varies from 30 min. to 24 hrs. The variation is due to differences in the medium in which the bacteria are exposed, in the method of exposure, and in the type of bacteria used. Those forms inhibited in their growth most readily by traces of O, the strictest anaerobes, are those which die off most rapidly on exposure. All anaerobes produce a pink zone around their surface colonies when grown on heated blood agar; but some, especially certain gram-negative bacilli recovered occasionally in cases of septic meningitis, develop a green coloration which replaces the pink within 30 min. after exposure of the plate to O. When the centrifuged sediment of a 24-48-hr. culture of such bacteria in fluid medium is rapidly oxygenated with an air or O current, it is possible to obtain faint but distinct positive tests with the usual chemical reagents for H_2O_2. With several characteristic anaerobes, however, peroxide reactions are not obtained when their cultures are examined in this way. The explanation of this discrepancy is obscure, but it seems likely that H_2O_2 is the agent responsible for the observed rapid death of anaerobes when exposed freely to O.

10874. MURTO, J. A. Über die Oligodynamie. *Acta Soc. Med. Fennicae "Duodecim" [Suomalaisen Lääkäriseuran Duodecim'in]* 13[Ser. A.](2): 1-26. [Art. 3] 1930.—A surface of dry agar on which the bacteria to be examined were spread out on a revolving table furnished the most exact results in oligodynamic studies. The zooglea content of a culture rendered bacteria more resistant to oligodynamic effect, which is propagated also through the air. Each of the elements affects the bacteria differently. Contrary to previous investigators, the author finds that inactivation and regeneration are not characteristic of oligodynamy. He believes that the oligodynamic effect consists in the discharge of atoms from an element; the action may be either favorable (discharge negative) or injurious (discharge positive) to bacterial growth. The atoms discharged by a positive element, by union with electrons torn from the element or by leaving their paths, may become negative and thus promote a marginal growth; e.g., in the system Sb and Cd plus *Mycobacterium phlei,* when the reaction reverts to positive, a ring of feeble growth is formed outside the margin, and later, a new outer marginal growth when the electrons unite with the atom. Oligodynamic diffusion, the place in the periodic system of elements having different actions, and parallelism of the other physical qualities of the elements, are among the considerations leading to the adoption of this theory.—*From author's summary (transl.).*

10875. PESCH, KARL L., und ELISABETH KRÄMER. Ernährungs-physiologische Typen bei Gärtner-Bakterien. *Zentralbl. Bakt I. Abt. Orig.* 118(3/4): 136-144. 1930.—Separation of types of Gärtner bacilli by their decomposition of arabinose and rhamnose in different nutrient solutions, as stated by L. Bahr, has been confirmed by subsequent tests on 200 Gärtner strains. A few more strains, besides the 4 Gärtner types described by Bahr, do not ferment either arabinose or rhamnose; these strains can be put into a special group. The authors differentiate the rare ammonia-strong from the more common ammonia-weak Gärtner bacilli by growth or lack of growth on synthetic NH_4Cl agars. Combination of Bahr's with the authors' results leads to differentiation of types of Gärtner bacilli according to the following scheme: The paratyphoid (Neukirch) C_1 strains (F. Weigmann, F. Kauffmann) which are similar serologically to Gärtner strains, agree in their dissimilation processes (Pesch-Kortenhaus) with the ammonia-positive Gärtner bacilli described in this work. Both the Bitter-Weigmann-Habs test and the demonstration of acid from arabinose are useless for identification of a doubtful strain as a Gärtner bacillus. A recognition, depending on the physiology (by means of the dissimilative metabolism), is possible only by use of different NH_4Cl agars (e.g., with dextrose, citrate, rhamnose and arabinose as sources of C).—*Authors' summary (transl. by O. B. Williams).*

10876. SCHLINGMAN, A. S. Notes on Bacillus welchii. *Jour. Lab. and Clin. Med.* 16(12): 1175-1184. 7 fig. 1931.—Considerable gas is evolved and there is cloudiness when *B. welchii* is seeded in Hibler medium and incubated at 37° C. Maximum growth follows 8-24 hrs.' incubation. Acid is produced (cultures pH 6.0-6.4, although initial may have been pH 7.6 or even more alkaline). In shake cultures in 2% agar medium containing 2% glucose, sufficient gas may be evolved to shatter the agar. The colonies are essentially lenticular and, if the seeding has been heavy, are small. With light seeding, colonies are larger and often appear broken along 1 edge. Pigeons are for the most part uniformly susceptible to *B. welchii* and its toxin. Crepitant swellings with a collection of edematous fluid follow intramuscular injection of pure cultures. Death may follow in 2-24 hrs. after administration of a virulent culture. Postmortem reveals degeneration and necrosis of the muscle tissue, which is discolored and may be torn apart by gas. Collections of edematous fluid in the subcutaneous connective tissue occur. Injections of sterile toxin are followed by practically the same changes as when whole cultures are injected, but no gas is produced. The appearance of the organisms in Hibler medium changes with age; they are on the whole smaller and strongly gram-positive when young, but larger in older cultures; in the latter, a greater % may be gram-negative. No reduction in activity of fluid toxin was noted after 5½ mo. storage at 2-3° C. in sealed amber bottles. Potency of antitoxin can be measured with great accuracy, the variable being as small as 0.00025 cc. per 350 gm. of the pigeon used for test.—*Author's summary.*

10877. SCHMIDT, ADAM. Vergärungsuntersuchungen an Typhusstämmen Jugoslawischer Herkunft. *Acta Path. et Microbiol. Scandinavica Suppl.* 3: 369-375. Map. 1930.—Fermentation tests of 13 sugars were made with 160 typhoid strains from Jugoslavia. Maltose, levulose, sorbite and arabinose gave variable, xylose constant, results. 112 strains fermented xylose; 48 did not. Xylose-positive strains predominated in the northeastern, xylose-negative strains in the northwestern, part of the country; this distribution seemed to be influenced by prevailing traffic conditions. In another well defined region, near the main highways, xylose-negative strains predominated; in other regions the 2 types were equally distributed.—*A. F. Reith.*

10878. [SHTIBEN, V., and M. MAKSIANOVICH.] ШТИБЕН, В., и М. МАКСИАНОВИЧ. К вопросу о культуральных и серологических признаках паратифа N. [Cultural and serological properties of paratyphoid N.] Вестник Микробиологии, Эпидемиологии и Паразитологии (*Rev. Microbiol., Épidémiol. et Parasitol.*) (8)3: 229-247; German summary, 351-352. 1929.—On the basis of the literature and a study of 38 cultures of *Bacterium paratyphi N*, the authors conclude that not all cultures described as paratyphoid N appear to be identical with the cultures of paratyphoid C described by German authors, and with Ivaschenzev's paratyphoid N. Positive cultures of paratyphoid N and C in their turn belong to 2 different types of *Salmonella*, one of which—$N_1=C_2$—by its properties may be considered as a variant of *Bact. suipestifer*. The other type—$N_2=C_1$—resembles types of *Bact. enteritidis* Gärtner. Paratyphoid $N_2=C_1$ differs culturally from $N_1=C_2$ by its action on rhamnose, having no effect on dulcit during the first 24 hrs., and causing acid formation on Bitter's medium. Also, the reaction to different carbohydrates, Bitter's reaction, serological properties, and pathogenicity for mice, definitely differentiate paratyphoid $N_2=C_1$ from $N_1=C_2$, and from *Bacterium paratyphi A, B,* and Breslau, *Bact. typhi murium,* and *Bact. enteritidis* Gärtner. 3 cultures of *Bact. paratyphi N* or *C* which had all the cultural and serological properties of both N_1 and N_2 were finally separated, and cultures of N_1 and N_2 were obtained. The question as to whether N_1 and N_2 are variants of a basic type—N—can not be answered at present.—*G. A. Lebedeff.*

10879. [SHTIBEN, V., and M. MAKSIANOVICH.] ШТИБЕН, В., и М. МАКСИАНОВИЧ. О типовой принадлежности паратифа N_1 и N_2. [Type allocation of Bact. paratyphi $C_1=N_2$ and $C_2=N_1$.] Вестник Микробиологии, Эпидемиологии и Паразитологии (*Rev. Microbiol. Épidémiol. et Parasitol.*) 9(1): 77-82; German summary, 133. 1930.—Comparison of cultural properties of many cultures of paratyphoid N and other types of the *Salmonella* group, showed that paratyphoid N_2 resembles the suipestifer type, and paratyphoid N_1, by its properties, could be differentiated from the Glässer, Voldagsen, and *Bact. suipestifer* strains. Cultural properties of the Newport and Stanley strains are exactly the same as those of the Breslau strain. Complete absence of agglutination of paratyphoid N_1 in Newport serum, and vice versa, showed that the paratyphoid N_1 and Newport strains are not identical; also, cross agglutination of paratyphoid N_1 and N_2 with the Stanley strain, showed that they differ serologically from the Stanley strain. On this basis, contrary to Bruce White and also to Aoki and Kurooda, the authors dispute the allocation of one of the types of paratyphoid N to the Newport type and consider paratyphoid N_2 as an independent type of the *Salmonella* group. Also, they confirm their previous (1929) conclusion that paratyphoid N_1 is serologically identical with, but culturally different from, the Glässer Voldagsen type. The authors suggest using the name *Bact. paratyphi C* for *Bact. paratyphi* $C_2=N_1$, and *Bact. paratyphi N* for *Bact. paratyphi* $C_1=N_2$.—*G. A. Lebedeff.*

10880. TROTZKY, W. L. Untersuchungen über die Länge der Bakterien. I. Die Bakterienlänge, ein individuelles Merkmal jedes Stammes. *Zentralbl. Bakt. I. Abt. Orig.* 112(3/4): 266-273. 1929.—The author sought to determine whether variations in length seen in a given smear are matters of chance or follow some law, like Quetelet's. Smears (stained with fuchsin) were projected through a microscope onto a ground glass screen, and the projected bacteria were measured at 1: 5000 magnification. The organisms studied were chiefly *Bacillus typhi abdominalis* and *B. dysenteriae* Shiga. It is concluded that bacterial length is not a matter of chance but an individual and constant characteristic of every strain,—sometimes the only characteristic by which strains otherwise identical can be distinguished. It is determined by inheritance, but may be altered (though not permanently) by animal passage, change of temp., etc.—*J. W. Churchman.*

10881. VERNONI, GUIDO, e S. FICHERA. Osservazioni sulla morfologia di un particolare spironema non

patogeno ottenuto e trapiantato in coltura pura. [Morphology of a non-pathogenic Spironema obtained and transplanted in pure culture.] *Boll. Soc. Italiana Biol. Sper.* 3(8): 1057-1064. 1928.—Detailed description of a spirochaete isolated from a mesenteric lymphatic gland of a goat. In the cycle of development of this microorganism, there is a granular phase: the spirochaetes disappear from the culture and only minute granules are discernible, which, in new sub-cultures, regenerate spirochaetes. Special spherical elements are observed, capable of movement, and unusual forms similar to flagellates. Many of the forms observed correspond exactly to analogous unusual forms described in the *treponema* of syphilis. The spirochaetes, in view of these observations, seem to constitute a group by themselves, similar in some points to protozoa and in others to bacteria.—*G. Vernoni.*

10882. **WILSON, G. S. The gaseous requirements of B. abortus (bovine type).** *British Jour. Exp. Path.* 12: 88-92. 1931.—*Bacillus abortus* bovine type requires both O and CO_2 for development, optimum concentrations are 20% O and 5-10% CO_2, the remainder of the atmosphere being some inert gas such as N or H. Contrary to frequent statements, lowered O pressure is less favorable to growth than is that of the air. The rôle of CO_2 in promoting growth is discussed, with the conclusion that it acts, not by altering the acidity of the medium, but by virtue of its power of diffusing rapidly through the intact cell wall and of giving rise to an increase in intracellular H-ion concentration.—*J. Bland.*

10893. **BOURNE, A. I.** Insect pests of Massachusetts orchards in 1930. *Mass. Fruit Growers' Assoc., Inc.* 37: 123-129. 1931.

10894. **COTTERELL, G. S.** The occurrence of Sahlbergella spp. and other pests of cacao in Fernando Póo, San Thomé and the Belgian Congo. *Gold Coast Dept. Agric. Bull.* 20. (2nd Conf. W. African Agric. Officers vol. 2.): 162-171. 1930.

10895. **FRANZ, E.** Der Erdbeerstecher. [Strawberry weevil.] *Natur u. Mus.* [*Frankfurt a/M*] 61(5): 218. 3 fig. 1931.—A brief description of the injury* of *Anthonomus rubi** and *Phyllobius oblongus** to strawberries.

10896. **GRASSÉ, PIERRE P.** Un ravageur des arbres fruitiers: La Zeuzère. *Prog. Agric. et Vit.* 92: 544-547. 1929.—The life cycle, distribution, habits and food plants of *Zeuzera pyrina* L. and *Z. aesculi* L. are described. Control or eradication may be effected by proper application to soil or tree of CS_2, $Ca(CN)_2$, ethyl acetate, benzine or paradichlorobenzene or by the use of light traps.—*K. S. Markley.*

10897. **ILLINGWORTH, J. F.** Pests of pineapple in Hawaii. *Proc. Hawaii Ent. Soc.* 7(2): 254-256. 1929.—The pests are listed as (a) affecting the root system, and (b) affecting the fruit, stem and leaves, with notes on the damage they cause.

10898. **JARY, S. G.** A note on the strawberry and raspberry bud weevil, Anthonomous rubi (Herbst). *Jour. So.-Eastern Agric. Coll. Wye, Kent* 28. 147-152. 5 fig. 1931.—Description, life history, habits, and control measures.

10899. **LEONARD, M. D.** Further experiments with nicotine-oil for the control of the codling moth in the Pacific Northwest. *Jour. Econ. Ent.* 23(1): 61-75. 1930. —40% nicotine sulphate, ½ pt., and lubricating oil emulsion, ¾-1¼ gals. to 100 gals. water gave varying results in control of the codling moth [Carpocapsa pomonella], but in most cases results equalled or bettered those obtained with lead arsenate, 2 lbs. to 100 gals. It is suggested that a satisfactory spray schedule would be 1 or 2 sprays of lead arsenate, followed by 1 or 2 of lead arsenate plus oil emulsion, finishing with 2 or 3 of nicotine sulphate plus oil emulsion. Control of other pests with the nicotine, particularly aphids, is mentioned.—*E. J. Newcomer.*

10900. **MACKIE, D. B.** The biological balance. *Pacific Rural Press* 122: 131. 1931.—Overproduction of canning peaches in California the past few seasons resulted in many acres being unharvested and furnished good conditions for the development of the peach twig borer, *Anarsia lineatella.* The spray program has been omitted in many orchards recently due to the financial depression and a very heavy borer infestation is expected next season unless extra control measures are adopted.—*C. S. Pomeroy.*

10901. **MONASTERO, SALVATORE.** Il Ficus carica L. infestato dal Cossus cossus L. *Bull. Ist. Zool. R. Univ. Palermo* 2(2/3): 41-44. 1930.—*Cossus cossus* observed on *Ficus carica* near Palermo. There are brief notes on its habits.

10902. **NEWMAN, L. J., and B. A. O'CONNOR.** Fruit fly (Ceratitis capitata). A further series of trapping or luring experiments. *Jour. Dept. Agric. Western Australia* 8(2): 316-318. 1931.—As a result of tests the authors recommend Clensel 1: 30 in water as luring agent, with renewal in cool weather every 10-12 days. The most effective time for trapping is July-December, with 2 as the minimum number of traps per tree.

10903. **WALKER, MARVIN H.** The story of the Mediterranean fruit fly. 39p. Col. frontispiece. 6 fig. Florida Grower: Tampa, 1929.

ECONOMIC ENTOMOLOGY

CEREAL, FORAGE, AND OTHER FIELD CROPS

(See also in this issue Entries 9244, 10949, 11039, 11630, 11849)

10904. **CORBETT, G. H.** The bionomics and control of Leptocorisa acuta Thunb. with notes on other Leptocorisa spp. in Malaya. *Dept. Agric., Straits Settlements and Fed. Malay States, Sci. Ser.* 4. 1-40. 6 pl. (2 col.), 1 fig. 1930.—Five species of *Leptocorisa* occur in Malaya, of which *L. acuta* is responsible for most of the damage to rice. Its economic status, seasonal history, and developmental period according to host grass is discussed. Keys to Malayan spp., of *Leptocorisa,* and descriptions of several, with notes on their life history, are given. An unidentified chalcid egg parasite is described. *Euagoras plagiatus* and *E. sordidatus* are predators of minor importance. Uniformity of variety and planting season in a given area would reduce damage. *L. acuta* swarms to flowering grasses, before attacking the rice, and they can be captured in large numbers by various devices which are described.

10905. **GROSSMAN, EDGAR F.** Biology of the Mexican cotton boll weevil. V & VI. *Florida Ent.* 14(3): 45-52; (4): 66-71. 1930.—Of 20,000 boll weevils (*Anthonomus grandis*) placed in hibernation quarters, individuals emerged daily from March 1st to the middle of July every yr., regardless of climate. When the boll weevil is physiologically prepared to quit hibernation, it does so, daylight, temp. increases, and rainfall hastening the process but slightly.

10906. **GROSSMAN, EDGAR F.** Biology of the Mexican cotton boll weevil [Anthonomus grandus] VII: The boll weevil in artificial hibernation quarters. *Florida Ent.* 15(2): 21-27. 1 fig. 1931.—The reliability of data generally obtained from hibernation cages is so questionable that the general use of cages as indicators of probable weevil distribution and population is unwarranted. A new type of cylindrical cage for holding Spanish moss, permitting determination of the percentage of weevils actually hibernating, indicated that of 20,900 weevils placed in 24 cages only 30.84% actually entered hibernation. The weevils sought the higher and moister places. Survival based on total number placed in cages ranged from 5.4 to 29.7%; on number actually hibernating, from 50.5 to 85.9%.

10907. **KÖRTING, A.** Ueber die Entwicklung der grauen Gerstenminierfliege (Hydrellia griseola Fall.) bei verschiedener Ernährung. *Zeitschr. Pflanzenkrank. (Pflanzenpath.) u. Pflanzenschutz* 41(7): 321-333. 3 fig. 1931.—When fed on oats the insects were smaller and ate less and more slowly than when on barley. Only 42% of the larvae pupated on oats as against 100% on barley.

10908. **JOHNSTON, H. B., and R. C. MAXWELL-DARLING.** On the occurrence in the Sudan of Locusta migratorioides, Rch. & Frm., and its associated phases. *Bull. Ent. Res.* [*London*] 22(3): 399-416. 1931.—Swarms of *L. migratorioides* arrived in the Sudan unexpectedly in the summer of 1930. It seems to have a cycle of phases. Phase *solitaria* equals *L. danica,* and is non-

migrant; phase *transiens* is non-migrant; phase *congregans* is transitional; phase *gregaria* equals *L. migratoria*, and is probably non-migrant; *L. migratorioides* is regarded as the extreme of phase *gregaria;* phase *dissocians* occurs after the breaking of a swarm. Data are presented on the incubation period of egg-pods laid by immigrant swarms, description of larvae from known *L. migratorioides* parents, and data on the transformations from one phase to another.

10909. KUWAYAMA, SATORU. The principal insect pests of the rice plant in Hokkaido. [In Japanese.] *Bull. Hokkaido Agric. Exp. Sta.* 47. 1-107. Illus. 1928.

10910. LEAN, OWEN B. On the recent swarming of Locusta migratorioides, R. & F. *Bull. Ent. Res.* [*London*] 22(3): 365-378. 9 maps. 1931.—A study was made of the swarming and flights by periods from June 1928 to January 1931. The swarming phase develops at most in 3 localities, probably only in 1: the lake region of the middle Niger, being the principal permanent breeding ground. Lake Chad is probably a secondary breeding ground. Control should be directed at the permanent breeding grounds, which are all located in the Savannah belt.

10911. LEPLAE, EDM. Le ver rose du coton dans la région du lac Kivu. [Pink boll worm north of Lake Tanganyika, Belgian Congo.] *Bull. Agric. Congo Belge* 19(2): 262-270. 1 pl., 4 fig. 1928.—*Pectinophora gossypiella* is described and its recent establishment in Belgian Congo is recorded.

10912. MESNIL, L. Contribution à l'étude de trois Coléoptères nuisibles aux céréales. *Ann. Epiphyties* 16 (3/4): 190-208. 5 pl., 7 fig. 1930(1931).—Descriptive comparisons of adults* and larvae* of *Lema cyanella** and *L. melanopus**, and of the biology and damage* done to the foliage by each. *Lema cyanella* attacks wheat, and rarely barley, while *L. m.* attacks oats and barley. *Chaetocnema aridula* burrows as a larva in the basal portions of the stem* of oats, and rarely wheat. Its larva* and adult* are described.

10913. MILLER, N. C. E., and H. T. PAGDEN. Preliminary observations on Sogata spp. pests of padi. *Dept. Agric., Straits Settlements and Fed. Malay States, Sci. Ser.* 3. 10-14. 1930.—*Sogata* sp. probably *pallescens* is at times a serious pest in the rice fields. Notes are presented on its life history.

10914 SITOWSKI, LUDWIK. Roztocze jako szkodniki traw zbozowych. [Acarina as grain pests.] [With German summary.] *Roczniki Nauk i Leśnych* (*Polish Agric. & Forest Ann.*) 17(3): 427-429. 1927.—*Pediculopsis graminum* was observed as a pest of rye on low soils, where about 50% of the grain was damaged. The ♀♀ were found inside the culms. In the body cavity 27 eggs were found (Kaufmann found 500). This discrepancy is explained by assuming that *P. graminum* is partly viviparous and partly oviparous.—*Author's summary* (*transl.*).

10915. TAYLOR, JOHN SNEYD. Notes on the biology of Laphygma exempta Walk. and L. exigua Hbn. (Lep., Noctuidae). *Bull. Ent. Res.* [*London*] 22(2): 209-210. 1931.—*L. exempta* occurs as an army worm in Transvaal, its outbreaks occurring at uncertain and irregular intervals. The egg period is 3-8 days, larva 18-24 days, pupa 12-36 days. Its enemies include *Disophrys iridipennis* and *Chelonus erythropus*. *Laphygma exigua*, the false army worm, attacks many plants, especially *Amarantus paniculata*. The egg stage is 3-12 days, larva 17-20 days, pupa 9-48 days. There are several enemies.

ECONOMIC ENTOMOLOGY

TRUCK AND GREENHOUSE CROPS

J. E. GRAF, *Editor*

(See also in 6(3): Entries 6162, 7778, 7853, 8767; and in this issue 9243, 11018)

10916. CAESAR, LAWSON. Insects attacking vegetables. *Ontario Dept. Agric. Bull.* 359. 1-67. 47 fig. 1931.—A handbook on vegetable insects and their control. A statement is given on the reasons for using different insecticides, together with formulae, methods of application and spray equipment. Pests are listed under the various crops affected and there is a discussion of those with general feeding habits. Each insect is described in general terms, and the life history, food plants, nature of injury and control are described briefly in each case.—*J. E. Graf.*

10917. CHERIAN, M. C. Life-history notes on Lamprosema indicata (Pyralidae), a caterpillar pest of Chrysanthemum. *Jour. Bombay Nat. Hist. Soc.* 33(4): 857-860. 1929.—The caterpillars generally attack the leaves only, but have been reported to destroy the flowers also and to have sometimes brought about complete defoliation. The pest appears about the time of flowering. Description is given of the eggs, the larvae, and the adult moths. The eggs are generally laid under the surface of the leaves, 2-3 days after emergence; 9 ♀♀ laid 2,966 eggs, averaging 330 per moth, maximum 499. The larvae undergo 4 moults in all, the 1st instar taking 3 days, the 2nd, 3rd, and 4th, 2 days each. Cocooning takes about 2 days, the pupal period lasts 6 days, and the whole life cycle covers 23-30 days. A small Elasmid wasp, *Elasmus indicus*, parasitizes the caterpillars, although not in sufficient numbers to check the pest. Lead arsenate and Paris Green were effective in controlling the pest—the former used as a spray at the rate of ½ oz. to a gallon of water being the more effective. Tables of records are given of egg laying, life history, and longevity of adult moths.—*M. Sharif.*

10918. HOFFMANN, WILLIAM E. A Pentatomid pest of growing beans in South China. *Peking Soc. Nat. Hist Bull.* 5(3): 25-26. 1 pl. 1931.—*Holyomorpha picus* does considerable damage in the region of Canton to the flowers, leaves, stems and pods of *Vigna sesquipedalis* and *Phaseolus lunatus*, the fruit of *Solanum nigrum*, stems of *Celosia argentea*, and *Basella rubra*, and flowers of *Hibiscus rosa-sinensis*. Injury is by both nymphs and adults. The adults are found from early April until late October. The first generation is completed before the middle of June. There are at least 4 generations a yr. in Kwang Tung Province. The destruction of nightshade plants will help materially in the control of this species. The eggs, nymphal stages and adult are figured.

10919. JHAVERI, T. N. India: Notes on Thrips tabaci (Heliothrips indicus), a pest of onion and chillies. *Internat. Bull. Plant Protect.* [*Rome*] 5(4): 55-56. 1931.—Brief notes on the author's results in control of thrips on onion by cultural, remedial and preventive measures; and on the technique of finding thrips ova in the leaf tissues of chillies.

10920. KINGSBURY, JEANNETTE A. A new dahlia pest. *Bull. Amer. Dahlia Soc.* 12(57): 31. 1931.—Report on observations (3 yrs.) on damage by a leaf hopper, *Entylia carinata* (Forst), which is frequently mistaken for dry weather injuries. A pyrethrum product for controlling both sucking and chewing insects is recommended.

10921. P[RING], G. H. Glue as a control for red spider. *Missouri Bot. Gard. Bull.* 19(2): 39-40. 1 pl. 1931.—Successful control of red spider in the garden was obtained by spraying with 1 lb. powdered glue for 4 or 5 gallons of water. The glue is first dissolved by heating and then poured into cold water and agitated until thoroughly mixed. In a few days the glue peels off taking the mites with it.*

10922. RAMACHANDRA RAO, Y. A preliminary note

on the successful treatment of the jasmine bug (Antestia cruciata) by dusting calcium cyanide. *Madras Agric. Jour.* 18(1): 2-5. 1930.—Report of preliminary studies of life history and control. The principal injury is caused by adults feeding on the tender shoots and flower buds. Dusting with $Ca(CN)_2$ was effective in dropping the bugs from the plants but owing to the recovery of a portion of the insects, it is advisable to pick up all the insects dropped from the plants.

10923. **SILVA, A. ALVES da. Como se comportaría la Phthorimaea operculella en el Uruguay.** *Rev. Facult. Agron. [Montevideo]* 4. 57-73. 7 fig. 1931.—A discussion of the life history including duration of the various stages, distribution and control measures of the potato tuber worm in Uruguay.

10924. **STANILAND, L. N., and C. L. WALTON. Notes on some agricultural and horticultural pests in Bristol Province. 1. The beet carrion beetle (Blitophaga opaca) and its control.** *Jour. Bath & West & Southern Counties Soc.* 5: 174-176. 1 pl. 1930/1931 [1931].—Note on an outbreak. The beetles occur in the vicinity of woodlands. Mangolds were heavily injured, other plants were not affected. The larvae hide in galleries in the soil when alarmed. Experiments showed that infestation can be prevented or held in check by arsenate of lead dust early in June.

10925. **WALTON, C. L. Notes on some agricultural and horticultural pests in the Bristol Province. III. Notes on a serious tomato pest (Scutigerella immaculata).** *Jour. Bath & West & Southern Counties Soc.* 5: 178-181. 1 pl. 1930/1931[1931].—*S. immaculata* appears to be the cause of a characteristic failure of crop. It feeds on the root hairs of the plants. The plants growing in a range of glasshouses were seriously stunted. Since the pest may be found at a depth of 3 feet, control will be difficult.

10926. **BAGNALL, RICHARD S. Some insects of the buckthorn.** *London Naturalist* 1930: 75-76. 1931.—Notes on 2 gall-midges (*Perrisia rhamni* and *Contarinia frangulae*) on *Rhamnus frangula,* being first British records; an unnamed gall-midge on *R. catharticus;* and briefer notes on various other insects of buckthorn in England.

10927. **CHEN, H. T. A chrysomelid skeletonizer of bamboo.** *Nat. Hist. Soc. Fukien Christian Univ. Foochow, China* 1: 39-43. 1928.—An undetermined chrysomelid beetle is described, with notes as to the injuries produced on bamboo, and as to its natural enemies.

10928. **CLARK, ARTHUR F. Paropsis dilatata Er. in New Zealand. Preliminary account.** *New Zealand Jour. Sci. and Technol.* 12(2): 114-123. 8 fig. 1930.—*P. dilatata* is an Australian Chrysomelid, first recorded in New Zealand in 1916. A detailed survey of the Eucalypt plantations in 1928 showed that the insect is a serious pest of several species. Eggs are laid on the leaves, and both adults and larvae feed on the edges of the foliage. Pupation takes place in the ground. Pre-adult stages last 50-60 days. Hibernation is in the adult stage beneath the bark. The number of generations is uncertain at present, at least 2 being likely. The insect is restricted to the East of the South Island of New Zealand. There are no practicable silvicultural or mechanical methods of control, and the importation of parasites from Australia is recommended.—*A. F. Clark.*

10929. **FELT, E. P. The Norway maple Nepticula (Lepidoptera).** *Proc. Ent. Soc. Washington* 32(8): 146-149. 1930.—*Nepticula sericopeza,* probably recently introduced from Europe, occurs in New Hampshire, Massachusetts, Connecticut, Rhode Island, New York, New Jersey and Pennsylvania on the Norway maple. Data are given on the injury to leaves and seed, activity of moths, characters of larva and cocoon.

10930. **FELT, E. P. Protection of trees from insects.** *Ann. Rept. Quebec Soc. Protect. Plants* 21: 43-48. 1928-1929(1929).—Brief biographical data are given for 4 early New York entomologists, namely, Fitch, Lintner, Comstock and Slingerland, and these are followed by short accounts, with indications of their economic status, of a long series of insects occurring on shade trees. Some of the more important of these are: forest tent caterpillar, *Malacosoma disstria,* white-marked tussock moth, *Hemerocampa leucostigma,* bagworm, *Thyridopteryx ephemeraeformis,* elm leaf beetle, *Galerucella leuteola,* willow leaf beetle, *Plagiodera versicolora,* Japanese beetle, *Popillia japonica,* satin moth, *Stilpnotia salicis,* sugar maple borer, *Glycobius speciosus,* leopard moth, *Zeuzera pyrina,* hickory bark beetle, *Scolytus quadrispinosus,* Norway maple aphid, *Chaitophorus lyropicta,* San Jose scale, *Aspidiotus perniciosus,* elm scale, *Gossyparia spuria,* golden oak scale, *Asterolecanium variolosum* and the cottony maple scale, *Pulvinaria vitis.*—*E. P. Felt.*

10931. **MARELLI, CARLOS A. La plaga de los gorgojos de los eucaliptos. [Eucalyptus weevils.]** *Rev. Soc. Ent. Argentina* 1(1): 14-22. 4 pl. (1 col.), 2 fig. 1926.—**DACNIROTATUS bruchi*** and *D.* **platensis** are described as new although previously so described in Mem. Minist. Obras Pub. Buenos Aires 1924-1925. Larvae and nymphs of *D. bruchi* are described and figured, with discussion of habits. Measures taken to combat the pest, which is extremely destructive to eucalyptus in Argentina, are described in detail.

10932. **MOZNETTE, G. F. How some factors limit efforts for artificial control of the pecan nut case-bearer in the Southeast.** *Nation. Pecan Assoc. Bull.* 4(1): 40-45. 1930.—The author discusses the possibilities and limitations in control of *Acrobasis caryae* Grote observed during experimental work. He stresses the importance of coating the eggs of the first generation with contact sprays to destroy the embryo.

10933. **SALMAN, K. A. Notes on the immature stages and biology of a birch case-bearer.** *Ann. Ent. Soc. Amer.* 22(3): 480-488. 1929.—*Coleophora salmani,* which has seriously injured white and gray birches in Bar Harbor, Maine, has 1 generation a yr. Eggs are laid in mid-July on the lower surface of leaves of *Betula alba, Corylus americana,* and *Alnus;* they hatch the 1st week of August. The 1st-instar larva mines in the leaves and does not form a case. The 2nd- and 3rd-instar larvae form cases and the latter stage hibernates on twigs. Most 5th-instar larvae have pupated in their cases by the 1st week in July. In addition to the 3 fall host plants mentioned above, spring larvae attack *Betula populifolia, Salix* spp., and *Quercus rubra,* especially the first. Most adults do not emerge till the 2nd week in July. Adult ♀♀ live 7-10 days, adult ♂♂ 6-8 days. *Trombidium* sp. feeds on the moth eggs. *Hemiteles tenellus, Itoplectis conquisitor,* and *Orgilus* sp. were reared from pupae. The egg, larval instars (except 4th), 4 types of cases, and the pupa are described.—*M. W. Boesel.*

10934. **SCHOEVERS, T. A. C. Bladwesp-eieren in wilgetwijgen. [Saw-fly eggs in willow twigs.]** *Tijdschr. Plantenziekten* 37(4): 91-92. 1 pl. 1931.—The egg pockets of *Pteronidea (Nematus) miliaris* Pz. found on willow twigs are described.—*H. L. G. de Bruyn.*

10935. **SCHWERDTFEGER, F. Die Ermittlung der Mortalität von Raupen während einer Insektenepidemie.**

Ein Beispiel für die Anwendung von Kotfängen zur Behandlung epidemiologischer Probleme, zugleich ein Beitrag zur Epidemiologie des Kiefernspanners. [Determination of the mortality of caterpillars during an insect epidemic. An example of the use of excrement measurements in dealing with problems in epidemiology, with account of the epidemiology of Ennomos lituraria]. *Anz. Schädlingsk.* 7(8): 85-90. 6 fig. 1931.

10936. **TAYLOR, RAYMOND L.** A new host record for the white pine weevil. *Jour. Econ. Ent.* 23(3): 640. 1930.—*Pissodes strobi* on *Pinus montana*. The fly *Lonchaea corticis* Taylor is recorded on the weevil.

(See also in this issue Entries 9200, 9770, 10258, 10451, 10599, 10602, 10619, 10635, 10755, 10781, 10788, 10790, 11599, 11607, 11614, 11616, 11766, 11858)

10937. **BLANC, GEORGES, et J. CAMINOPETROS.** La transmission des varioles aviaires par les moustiques. *Rev. Gén. Méd. Vét.* 39(464): 456-465. 2 fig. 1930.—*Culex pipiens* can transfer avian variola in either chickens or pigeons, for periods of over a month, probably for the life of the mosquito. The disease is normal in course and sub-clinical attacks may occur, as shown by development of immunity.—*R. G. Perkins.*

10938. **[BOGOÏAVLENSKIĬ, N. A.]** БОГОЯВЛЕНСКИЙ, Н. А. Из наблюдений над флеботомусом в г. Казахе. [Observations on Phlebotomus in Kazakh, Azerbaijan.] Русский Журнал Тропической Медицины, Медицинской и Ветеринарной Паразитологии [*Russ. Jour. Trop. Med., Med. & Vet. Parasitol.*] 7(7): 461-469. 1929.—In summer and fall numerous specimens were caught and their habits and reactions observed. They showed a decided preference for white; yellow seemed to attract least. Artificial light proved very attractive,—in direct ratio to its intensity. Very few specimens were caught in spider webs, and although *Scutigera coleoptrata* is considered a natural foe, no attacks were observed. Copulation was observed in 3 cases. Sounds emitted were, contrary to Brack's statement, short and low, not high and monotonous as in Culicidae. Only ♀♀ bite; no ♂ was every noticed even to alight on man. The time of biting is mostly at night, towards morning, light being an unfavorable condition. In general, *Phlebotomus* is not so annoying as are Culicidae. The most delicate skin regions are preferably chosen for biting. During the bite, which may continue for 4-5 minutes, ♀♀ are remarkably indifferent to outside stimuli. Subjectively, the bite is sharply painful and causes skin irritation, which disappears in 7-8 days. Maximum aggressiveness was shown in the last third of July. Larval mites observed as parasites; this is of interest since mites may, possibly, participate in the spread of infections by *Phlebotomus*. Repeated attempts to find eggs or larvae of *Phlebotomus* failed as usual. Although several eggs were laid in captivity, the author failed to observe the process; none of the eggs under observation hatched. Eggs were pale-yellow, 361.5 × 102μ in size. Duration of life in captivity was 3-7 days for ♀♀, 4 days at most for ♂♂.—*B. Van Rosen.*

10939. **FLETCHER, T. BAINBRIGGE, and S. K. SEN.** A veterinary entomology for India. XIII. *Jour. Central. Bur. Animal Husb. & Dairy. India* 4(4): 127-138. 5 pl. 1930.—A discussion of warble flies (Oestridae) of India. *Hypoderma lineata* (most common), *H. bovis* (chiefly attacking cattle), and *H. crossii* (chiefly attacking goats) are described. Warble flies are for the most part restricted to Western India, being absent in moister areas such as Madras, Assam, Burma, and Ceylon. The proportion of animals infested is 5-90%. Life histories, treatment of infested animals, and control measures, are quoted, chiefly from other sources.—*G. W. Rawson.*

10940. **HANCOCK, G. L. R.** Some records of Uganda mosquitoes and the ecological associations of their larvae. *Bull. Soc. Roy. Ent. Egypt* 14(1): 38-56. 5 pl. 1930.—Uganda is favourably situated for the study of the biology of inland waters, temperatures varying from that of thermal springs to glaciers; both fresh and salt water lakes occur. The almost complete absence of Anopheline larvae from waters covered with an oily scum is confirmed, they are rarely found in natural swamps when the concentration of ferric iron exceeds 10 parts Fe''' per million. Preliminary confirmatory experiments were inconclusive. The range of pH within which Anopheline larvae occurred was between 5.6 and 7.1. The pH range of the waters containing high concentrations of iron was 6-6.9. A few predaceous enemies of mosquito larvae are recorded including fishes *Barbus* sp. and *Haplochilus* sp., a species of *Haplochromis* is of doubtful value. The mosquito fauna of artificial containers is dominated by *Aedes argenteus*, the occurrence of Anophelines in such situations being negligible. Tree-hole forms have been inadequately studied; rock pool records include *Anopheles gambiae, Aedes vittatus* and *Aedes nigeriensis*. Swamps, ditches and water-holes (including pits dug for clay) are the main breeding places of Anopheline larvae. A richer fauna of such swamp species as *Anopheles mauritianus* is indicated when the microflora is rich. A few examples of typical swamps are given with genera of Algae found. A summary of the breeding places of Anopheline larvae indicates abundance of *A. gambiae* in exposed pools, being replaced as density of shade increases by *A. funestus* and *A. mauritianus*. *A. implexus* is recorded only from dense shade such as under clumps of palm trees. 16 spp. of Culicines are listed from swamps, ditches and water-holes. The mosquitoes noted in dwellings were *Anopheles gambiae, A. funestus, A. transvaalensis, A. marshalli* and *A. theileri*. A doubtful record of *A. implexus* is included. *A. mauritianus* is noted from a tent but without evidence of having fed. Culicines recorded from dwellings are *Aedes argenteus, Taeniorhynchus fuscopennatus, Culex fatigans, C. univittatus* and *C. horridus*. A high malarial infection rate of *A. gambiae* (*costalis*) and *A. funestus* is indicated and *A. theileri* has been found infected. 12 spp. of *Anopheles* and 76 spp. of Culicines are listed in an appendix. Photographs are included of typical breeding places.—*G. L. R. Hancock.*

10941. **LA FACE, LIDIA.** Sulla resistenza delle larve degli anofelini alla salinità. [Resistance of anopheline larva to salinity.] *Riv. Malariologia* 7(1): 18-30. 1928.—Laboratory experiments have shown that *Anopheles elutus* tolerates a greater concentration of NaCl than *A. maculipennis*. The resistance of *A. superpictus* to the salt content is intermediate. The gradual adaptation to an increase of the salt concentration differs according to each species.—*Author's abstract.*

10942. **ROUBAUD, E.** Cycle autogène d'attente et générations hivernales suractives inapparentes chez le Moustique commun, Culex pipiens. *Compt. Rend. Acad. Sci. Paris* 188(10): 735-738. 1929.—In France, *C. pipiens* dies at the approach of winter, except for fertilized ♀♀ of the autumn brood which have not begun ovipositing. These hibernate during the cold weather, but are unable to deposit their eggs until they have fed on blood. Recent observations show that there may be exceptions to the foregoing rule. In a Parisian cellar warmed all winter to above 20° C. and containing open water, a continuous succession of generations of mosquitoes was observed from November to February, the ♀♀ not having

had access to blood or any substitute organic fluid.—*M. K. Chapin.*

10943. **ROUBAUD, E. Nouvelle contribution à l'étude du Zootropisme anophélien (Anopheles maculipennis).** *Bull. Soc. Path. Exotique* 24(3): 229-246. 7 fig. 1931.—Roubaud here elaborates his view that the races of *A. maculipennis* which attack man are the poorly armed strains which tend to become eliminated because less abundantly nourished and therefore less fecund.

10944. **ROUBAUD, E., et H. GASCHEN. Sur l'adaptation zoophile de l'Anopheles maculipennis. (Rapports entre la différenciation maxillaire et la fécondité.)** *Bull. Soc. Path. Exotique* 24(3): 203-209. 1 fig. 1931.—Comparing ♀ *A. maculipennis* from Morocco captured in dwellings (strains living on any animal, including man), mosquitoes from Jugoslavia (strains with a similar undifferentiated diet) and mosquitoes from La Vendée, southern France, and Marmorta, northern Italy (strains which feed on domestic animals alone), the authors found that the dietary change involved, when man ceased to serve as a host, had been accompanied by an increase in the maxillary dentition of the ♀ mosquitoes, and also by an increase in the number of eggs laid, the more abundant food supply permitting a greater fecundity. The indirect advantage to the human race is the result of a more direct advantage to the mosquito.

ECONOMIC ENTOMOLOGY

BIOLOGICAL CONTROL

H. S. SMITH, *Editor*

(See also in this issue Entries 9196, 10884, 10917, 10927, 10928, 10933, 11737)

10945. **BALACHOWSKY, A. Observations biologiques sur les parasites des Coccides du Nord-Africain.** *Ann. Epiphyties* 14(4): 280-312. 18 fig. 1928.—A discussion of the distribution, prey (or hosts), and effectiveness in control of numerous coccidophagous insects (mostly Coleoptera and Hymenoptera, with mention of a few Diptera, Lepidoptera, and Neuroptera).

10946. **BRIAND, L. J. Notes on Chrysopa oculata Say and its relation to the Oriental peach moth (Laspeyresia molesta Busck.) infestation in 1930.** *Canadian Ent.* 63(6): 123-126. 1931.—The larvae of *C. oculata* and *C. albicornis*, due to scarcity of aphids in the Niagara peninsula in 1930, began to attack the eggs and larvae of *Laspeyresia molesta*, and were of great importance. The egg stage lasts 4-11 days, larval stage 14-28 days, and pupal stage 8-22 days. Two larvae, fed exclusively on eggs, consumed 613 and 620 eggs each. At the peak of the 2nd moth generation, various counts showed 50-60% of the moth eggs sucked by chrysopid larvae. The larvae destroyed a considerable number of eggs parasitized by *Trichogramma minutum*, but, on the other hand, this parasite destroyed many chrysopid eggs.

10947. **GRAHAM, A. R. The present status of the Larch sawfly (Lygaeonematus erichsonii Hartig) in Canada, with special reference to its specific parasite, Mesoleius tenthredinis Morley.** *Canadian Ent.* 63(5): 99-102. 1931.—In 1912 introductions of *M. tenthredinis* were made from England to Manitoba, and in 1916 to Quebec and Ontario. At Treesbank, Manitoba, parasitism in 1916 was 19%, in 1917 22%, in 1919 40%, in 1920 66%, in 1927 88%. Parasites have been recovered at points 200 miles from the point of release. The infestation in centers of parasite release have been greatly reduced. Parasitization under laboratory conditions is reported.

10948. **HOWARD, L. O. Aphelinus mali and its travels.** *Ann. Ent. Soc. Amer.* 22(3): 341-368. 1929.—A compilation of the known data concerning this North American chalcidid parasite of the woolly aphis (*Eriosoma lanigerum*), especially as regards its introduction into various parts of the world. The details of the various introductions, including some personal experiences and the substance of the author's correspondence, are given. The parasite is well established in Argentina (introduced 1921, from Uruguay), Chile (intr. 1922, from Uruguay), France (intr. 1920, from U. S. A.), Holland (intr. 1924, from France), Italy (intr. 1921, from France and Uruguay), and New Zealand (intr. 1921, from U. S. A.). It is perfectly established in Uruguay (intr. 1920, from U. S. A.). It is doing some good work in Australia (intr. 1922-1923, from New Zealand), South Africa (intr. 1920, from U. S. A.), and Spain (intr. 1926, from Italy and Uruguay). In England, conditions have proved unfavorable for it (intr. 1923, from France). Failure apparently has resulted also in Japan (intr. 1926, from U. S. A.). Introduction has been indifferently successful in Germany (1923, from Uruguay). Information from the following countries is insufficient or lacking: Austria, Belgium, Poland (intr. 1928, from England), and Switzerland (intr. 1923, from Germany).—*M. W. Boesel.*

10949. **IMMS, A. D. Observations on some parasites of Oscinella frit Linn. Part 1.** *Parasitology* 22(1): 11-36. 14 fig. 1930.—The stem of infestation of *O. frit* in England is attacked by at least 2 spp. of hymenopterous parasites of considerable importance, *Halticoptera fuscicornis* Walk. (Chalcidoidea) and *Rhoptromeris eucera* Htg. (Cynipoidea). It is also parasitised to a much lesser degree by *Loxotropa tritoma* Thoms. (Proctotrypoidea). These 3 spp. are described and figured in detail. They have been reared by the writer from host puparia obtained in the Harpenden district; they have also been reared in the Leeds and Oxford districts by others. They attack the host in the larval stage of the latter and emerge from the puparia. All 3 spp. are characteristic parasites of cyclorrhaphous Diptera. In the Harpenden district a parasitism of 27% was observed in 1926 and of 37% in 1927, *R. eucera* being the dominant parasite. Evidence is brought forward which appears to indicate that the parasites, collectively, become more abundant as the season advances, with the result that *O. frit* affecting late sown oats suffers markedly heavier parasitisation than when it attacks oats sown earlier. The time of maximum emergence of *O. frit* in out-of-door rearing cages during the years 1926 and 1927 coincided very closely with its period of greatest abundance in the field, as recorded by Cunliffe.—*A. D. Imms.*

10950. **JAMES, H. C. Methods for the biological control of the common coffee mealybug.** *Kenya Colony & Protect. Dept. Agric. Bull.* 1930: (1-16). 6 fig. 1930.—Four practical methods to be used by the coffee planter are described: The trees may be banded with kresotow to bar the ants, thus favoring the enemies of the mealybug; large numbers of the coccinellid, *Chilocorus angolensis** Crotch may be collected by boys and stored in preparation for the chief mealybug crises which usually occur at the principal flowerings. (The caged beetles live on a mixture of: hen's egg, 2 parts by weight; butter, 2 parts; and honey, 1 part.) Because an infestation of mealybugs is generally patchy, some beetles may be transferred to the infested parts from areas already clean or becoming so; and quantities of *C. angolensis* may be bred to prevent the extension of small outbreaks of mealybug. The breeding process consists essentially of infesting potato sprouts with mealybug and allowing the ladybird to feed and breed on them in suitable cages. Full directions are given for constructing the equipment and for breeding and subsequent liberation of the predator. The method is similar to that evolved in California for producing

Cryptolaemus montrouzeri Muls. Research into the adaptation of this method to other ladybeetles is in progress.—*W. V. Balduf.*

10951. **TAYLOR, RAYMOND L. The biology of the white pine weevil, Pissodes strobi (Peck), and a study of its insect parasites from an economic viewpoint.** *Entomologica Americana* [*Brooklyn*] 9(4): 167-246. 1 folding insert. 1929; 10(1): 1-86. 10 pl. 1929(1930).—In part A, the host, the author presents an historical summary of previous work on the bionomics and control of *P. strobi*. The reported size of the egg is corrected. The position of the food supply, not positive geotropism, is, apparently, the primary reason for the downward mining of the leaders by the larvae. Some data on the rate of mining are given. It is estimated that 80-90% of the young larvae die from starvation. The optimum time for parasitism is discussed, and evidence is presented that the weevil may fly or be wind-blown long distances. From dissection of 3009 leaders (mostly from eastern Massachusetts) it was found that the average number of mature weevil larvae per leader was about 12, of which about half emerge successfully, the remainder being destroyed by parasites and predators, and by mechanical injuries. Part B, the insect parasites, dealing with the result of the 1926-1929 investigations chiefly with material from eastern Massachusetts, is divided into 3 parts: (1) breeding methods, apparatus, and data secured; (2) biologies of each parasite sp., with a brief account of predators (clerids and the lepidopteron, *Dioryctria* n. sp.), and of nematodes found under the elytra of *Pissodes* and in the frass of weeviled leaders. In this section, for each of the primary or secondary parasites of *P. strobi*, data are given under the subheadings, introduction, synonymy, history, distribution, description (of all stages obtained), life cycle, habits, and effectiveness. The primary parasites obtained, in order of importance and with the approximate % of mature weevil larvae attributed to them, were: *Eurytoma pissodis* Gir., 5.9%, *Lonchaea corticis* Taylor, a facultatively parasitic dipteron, 5.4%, *Microbracon pini* Mues., 2.7%, *Eupelmus pini* Taylor, .9%, *Rhopalicus pulchripennis* (Cwfd.), .7%, *Cocloides pissodis* (Ashm.), .3%, *Calliephialtes nubilipennis* (Vier.), and *Spathius* sp. Secondary parasites obtained were: *Pleurotropis* n. sp. and *Eucoila* sp. (on *Lonchaea corticis*), and *Hemiteles humeralis* Prov. Based on emergence counts, these parasites, collectively, were credited with the destruction of about 16.4% of the mature weevil larvae. An annotated list of 26 spp. of parasites obtained from similar material (not necessarily parasites of *P. strobi*) by other investigators is given; an annotated list of 19 spp. of parasites bred incidental to the study, but probably not associated significantly with *P. strobi*, is also given. (3) A discussion of the feasibility of applied parasite control of *P. strobi*. Only *Eurytoma*, *Lonchaea*, and *Microbracon* were considered sufficiently effective to merit consideration in this respect. Their potentialities were "measured" with the aid of H. S. Smith's outline. It was concluded that, with present knowledge and conditions, control of this weevil by its native parasites is not feasible. Possibly parasites of certain other *Pissodes* spp. in the western U. S. A. and in Europe (a list of spp. from European *Pissodes* is given) might profitably be introduced. There is an extensive bibliography. —*R. L. Taylor.*

ECONOMIC ENTOMOLOGY

INSECTICIDES AND APPARATUS

C. H. RICHARDSON, *Editor*

(See also in this issue Entries 9358, 10788, 10896, 10899, 10902, 10917, 10920, 10921, 10922, 10924, 10932, 10950)

10952. **CHARLIERS, N. Dispositif pour l'obtention de jets insecticides finement divisés.** *Congr. Internat. Appareils Lutte Ennemis Cult. Tenu à Lyon Compt. Rend. Serv. Agric. Cie. P. L. M., Paris* 1929: 85-87. 1930. —The author describes a simple apparatus consisting of an ordinary household atomizer in which the piston has been removed and the body of the pump is connected to a steam valve giving about 28 lbs./sq. in. pressure. A finely divided warm mist (22-23°C.) is obtained which condenses on all parts of the plant even beyond the trajectory of the spray of the insecticide. This results in economy of the active product and offers possibilities to spray, in the cold, liquid insecticides which would lose their properties upon heating.—*N. Charliers* (*transl. by J. M. Ginsburg*).

10953. **DARRAGH, W. H. Fumigation of seed maize.** *Agric. Gaz. N. S. Wales* 42(5): 377-378. 1931.—Samples of seed maize were fumigated with CS_2 at different temps., and different rates for 24, 48, 72 and 96 hrs. Germination of the treated seed was compared with that of untreated seed. Practically no loss in germination occurred in the controls up to 96 hrs., even in the sample with the highest moisture content. However it is recommended that if maize containing a higher % of moisture must be fumigated, only the ordinary dosage of CS_2 (5 lb. per 1,000 cubic feet) should be employed for not more than 48 hrs., preferably on a cool day or over-night. Fumigation should be followed by thorough aeration of the seed.

10954. **JOHANSSON, EMIL. Försök med karbolineum- och oljeemulsioner vid vinterbesprutning.** [Tar-distillates and oil emulsions as winter washes.] *Sveriges Pomologiska Förenings Årsskr.* 31(4): 198-206. 1930. —The tar-distillates Carbosol, Monarch 30, and Mortegg used at the rate of 8%, had much the same effect as egg killing washes against insects, but they did not destroy the winter eggs of the Fruit Tree Red Spider (*Paratetranychus pilosus* (C. and C.) Volck. A commercial oil emulsion killed most of the eggs of this spider mite, but it is too expensive. Mineral oils, emulsified with cresol soap and used at 10%, were very effective against this mite. A combined spray containing 5% of a tar-distillate and 5% of a mineral oil was effective against insects and the mite as well. None of the washes used entirely prevented the hatching of the eggs of the mite. All the tar-distillates tried were effective at 5% against the Gooseberry Red Spider (*Bryobia ribis*, Th.).—*E. Johansson.*

10955. **MEIER, K. Arsen- und Bleirückstände auf Früchten von unbespritzten Obstbäumen. Ergebnisse der Versuche des Jahres 1930.** *Schweiz. Zeitschr. Obst.- u. Weinbau.* 40(5/6): 125-129. 1931.—The treatment of stone fruits with sprays containing Ca arsenate and Pb arsenate, mixed with 2.5% lime sulphur (the mixture of Ca arsenate amounting to 0.4%, that of Pb arsenate to 1.5-2%) showed that even when 3 applications of Ca arsenate were made after blossoming, the As residue was not high (0.17 mgm./kgm. fruit). The As residue from 2 applications of Ca arsenate made after blossoming was the same as that from one application of Pb arsenate, the Pb arsenate residue in this case being 0.45 mgm./kgm. fruit. Small fruits show the largest quantity of As residue. Ca arsenate acts more efficiently against mites on windfalls than does lead arsenate. Similar results were obtained with cherries. In dry and warm regions, Ca arsenate seems to cause more burning of the leaves than Pb arsenate. The causes of these phenomena are unknown.—*K. Meier.*

10956. **METCALF, C. L. Progress in spraying and dusting methods during the past seventy-five years.** *Trans. Illinois State Hort. Soc.* 64: 287-307. 1930(1931). —An address.

10957. **RICHARDSON, HENRY H. An insecticidal method for the estimation of kerosene extracts of pyrethrum.** *Crop Protection Digest* 32. 1-105. 1 pl., 2 graphs. 1931. also in *Jour. Econ. Ent.* 24(1): 97-105. 1931.—A method for evaluating pyrethrum extracts is described. Different strengths of pyrethrum extracts vary directly in the speed with which they paralyze house flies. (*Musca domestica* L.). A series of similarly performed tests indicated that the reproducibility of the results is great, especially the values for speed of paralytic action. The % mortalities produced by such a series extended over a wider range but statistical analysis indicated that this variation was well within the limits of errors due to random sampling. Typical paralytic curves are shown and the value of the 50% paralytic point (the time when 50% of the insects are paralyzed) for making comparisons is pointed out. For a series of various concentrations of pyrethrum extracts the differences in mortality were not very large. This criterion of toxicity can be used only for diagnosing differences between extracts which differ widely in concentration. Differences in speed of paralytic action between a ¾ pound and a 1 pound extract of a fairly powerful grade of pyrethrum powder (0.26% pyrethrum I) were easily distinguishable and were found to be clearly significant as indicated by statistical analysis. The differences in % mortality, analyzed similarly, were not significant.—*Author's summary.*

10958. **ROBERTS, O. C., and A. I. BOURNE. A test of certain spray materials.** *Mass. Fruit Growers' Assoc. Inc.* 37: 64-71. 1931.—There was not sufficient increase in the control of pests when Ca caseinate was added to the lime sulphur-lead arsenate mixture to warrant its use for that purpose alone; neither did it entirely prevent burn. Ca arsenate gave no better control of pests than Pb arsenate, and when combined with lime sulphur, is much more likely to burn the foliage. For this reason Ca arsenate is not recommended for general use on fruit trees unless aluminum sulphate is also added to the mixture in which case the efficiency of the combination may be materially reduced. CaS is an efficient fungicide and safe, but has a strong tendency to cause excessive wear on the machinery. Flotation S is efficient in the control of pests, does not cause injury to the foliage and its chief objection as a fungicide is the difficulty with which it goes into solution. It is at present one of the most promising substitutes for lime sulphur.—*Authors' summary.*

10959. **SCHMITT, N. Derris elliptica Benth., ein vegetabilischer und ungiftiger Insecticidlieferant. [D. elliptica, a vegetable and non-poisonous insecticide-yielding plant.]** *Angewandte Bot.* [*Berlin*] 12(6): 453-463. 5 fig. 1930.—The growing objection to the use of lead and potassium arsenates as insecticides has prompted a search for non-poisonous substitutes. Tropical arrow and fish poisons were suggested, and the root of *D. elliptica* was studied as a representative. The plant and root are described and methods are given for the use of the root against insect pests of animals and plants. It is concluded that such preparations are better than those of potassium arsenate or nicotine for similar purposes.—*R. D. Bienfang.*

10960. **THIEM, H., und L. KALANDADZE. Petroleum als Reblausbekämpfungsmittel. Zugleich ein Beitrag über das Ausbreitungsvermögen von Insektiziden.** *Zeitschr. Angewandte Ent.* 18(2): 319-343. 1931.—The action of petroleum on *Phylloxera* is independent of temp. and time. When wet with petroleum the insects and some of the eggs die only after some days. A portion of the eggs, petroleum wet, still remain capable of developing. Watering infected roots hinders the action of petroleum on the eggs. Insects from eggs treated with petroleum can develop on sound roots but not on roots sprinkled with petroleum. Because of the low surface tension of petroleum, it penetrates the ground well and thus moistens the roots. Petroleum has greater spreading power than other materials such as dendrin, florium, cuprex, and Turkey red oil. The spreading capacity of the emulsion depends on the kind and quantity of the insecticide as well as on its method of preparation. Petroleum emulsions, which have much less spreading capacity than undiluted petroleum, excel the carbolineum emulsions, dendrin and florium in this respect. The petroleum-soap-emulsions behave much more like undiluted dendrin.—*Authors' summary (transl.).*

10962. **ARMBRUSTER, L., und G. OENIKE. Die Pollenformen als Mittel zur Honig-Herkunftsbestimmung.** 116p. 23 pl., 309 fig. Karl Wachholtz Verlag: Neumünster in Holstein, 1929.—An extended discussion of the morphological forms of pollens of spp. of plants from which honeybees sometimes collect either nectar or pollen, some of these spp. being important sources of nectar from which commercial honey crops are produced. The purpose of these descriptions and illustrations is to enable officials engaged in the control of foods to determine the floral source of honeys examined, and in some cases to determine indirectly the country of origin. The chief purpose is to determine whether such honeys are of German origin or have been imported, and 4 plates of foreign pollens are given. There is a partial review of previous literature in this field (p. 7-30). Observations are first listed under generic and specific names of plants, arranged alphabetically, with an illustration of the pollen of the species in each instance. Following this, the pollens are grouped as to families (43), the families being arranged alphabetically, and finally the pollens are arranged according to their morphology, to facilitate identification of pollens encountered in honeys. 306 spp. are included in the study, chiefly of German origin, although some foreign pollens are included. Since the forms of pollens vary according to the medium in which they are preserved, the medium used is indicated.—*E. F. Phillips.*

10968. DANGEL, R. Couveuse électrique pour l'élevage des reines. [Electrical brooder for rearing queen-bees.] *France Apicole* 1931 (April): 75-76. 1 fig. 1931.—A temperature of 34° gave best results. The apparatus is described.

10969. DUNHAM, W. E. A study of hive temperatures in different areas by hourly readings. *Gleanings in Bee Culture* 59(6): 369-370. 1931.—The curve representing the hourly temperatures in the outer brood area shows that the temperatures most nearly approach those of the central brood area when the environmental temperatures to which the colony is subjected reach their highest level. The temperatures recorded hourly in the broodless area are the lowest of any region of the hive.

10970. ELSER, ERNST. Die chemische Zusammensetzung der Nahrungsstoffe der Biene. I. Der Pollen. II. Der Futtersaft der Königin. *Märkische Bienen-Zeit.* 18 (9): 208-221. 8 fig. 1928; 19(9): 210-215; (10): 232-235; (11): 248-252. 7 fig. 1929.—I. Microchemical studies of pollen indicated the following components: Water, fat, protein, invert sugar, cane sugar and dextrin. The studies were carried out on the pollen of *Picea excelsa, Campanula medium,* grass, *Taraxacum officinale, Aesculus hippocastanum, Anthriscus vulgaris,* and *Pinus silvestris,* the pollen being taken partly from the plant and partly from the pollen baskets of the bee.—II. The larval food of queens from 5 hives was examined daily during the period of larval growth. Data taken included the weight of the larva, the weight of the larval food, water, dry matter, fat, protein, invert sugar, cane sugar, pH and pollen. Microchemical analyses verified Langer's discovery that the larval food is a true glandular product.—*E. Elser.*

10972. GÖTZE, G. Variabilitäts- und Züchtungsstudien an der Honigbiene mit besonderer Berücksichtigung der Langrüsseligkeit. *Arch. Bienenkunde* 11(5/6): 185-279. 4 pl., 11 fig. 1930.—I. Exact measurements were made to determine theoretical types as a basis for breeding races of bees. Measurements were made chiefly upon: head breadth, thorax breadth, wing-length and venation, breadth of the metatarsi and hairiness. The east Asiatic and African bees are broad-headed (type megacephala), the central European bees have relatively small heads compared to the thorax. The Egyptian and Syrian bees occupy an intermediate position. II. As in Russia, the bees in northern central Europe average larger and are shorter tongued than those in the south, but the regularity is often disturbed by importations. In determining the proboscis length, only the 2nd segment of the labial palpus was measured and the total length of the proboscis was computed from it. A peculiar correlation between proboscis length and certain indices in the wing-veins (positions where the discoidal cross-veins join the 3 cubital cells) serves for the selection of the fully sexed bees for breeding, in which measurement of the proboscis length is not feasible. This striking correlation appears to prevail throughout central Europe. III. Breeding experiments with long-tongued forms from lower Austria showed that the long-tonguedness is retained also in Landsburg/Warthe. For carrying on experiments in crossing a mating-station was situated where there were no bees for 4.5 km. around. The isolation of long-tongued lines through selection and inbreeding from native material was unsuccessful. Crossing a long-tongued selected queen with a short-tongued selected drone in the F_1 generation yielded short-tongued worker offspring. In the F_2 (inbred) generation, besides short-tongued and long-tongued forms, intermediate forms also appeared. Consequently the tongue length behaves entirely as a genotypic character. Whether it thereby behaves only as an after effect which gradually diminishes and finally wholly disappears, as has occasionally been surmised, could not be determined in these limited investigations. Even the longest tongued bees hitherto known are not fully adapted to red clover. With each elongation of the proboscis red clover increases in usefulness, and of course is raised in increasing amounts. However, for attaining this objective, plant-breeding and bee-breeding must work together. Breeding forms of red clover now on hand, as the Danish "bee-clover," are workable theoretically by the longest tongued bees known, in excess of 50% efficiency.—*G. Götze (transl. by G. E. King).*

10973. HARRIS, W. V. A short note on the races of honey bees in Tanganyika territory. *Bee World* 12 (8): 90-91. 1931.—The author lists 3 races, *Apis mellifica unicolor, A. m. intermissa,* and *A. m. adansoni,* the last mentioned being the most common and abundant.

10980. MILUM, V. G. Brood rearing temperature and variations in developmental periods of the honeybee. *Ann. Rept. Illinois State Beekeepers' Assoc.* 29: 72-95. 3 fig. 1929 (1930).—The literature is reviewed, and observations published earlier (See B. A. 5(5): entry 14989) are presented, with additional observations on stimulation of brood-rearing. In colonies wintered outdoors, brood-rearing is usually stimulated by the activity of a flight period when brood nest temp. increases to 91-92° F., after a mid-winter quiescent period of no brood-rearing, but continuation depends on the ability of the colony to secure necessary supplies of nectar, pollen and water. Lower temps. in the brood nest, even 85°, were not uncommon in the early spring, although 90°-95° was the general rule, with the bees tending to hang outside at temps. above 95°.—*V. G. Milum.*

10983. PELLETT, FRANK C. American honey plants. 3rd ed. 419p. 205 fig. American Bee Journal: Hamilton, Illinois, 1930. Pr. $3.—In the 3rd, as in the previous editions, the honey plants of No. America including those valuable to the beekeeper for pollen are arranged in alphabetical order under their vernacular or English names, the scientific names being given in cross references. Numerous related subjects, as nectar secretion, poisonous honey, honeydew, propolis, weather and honey production, and descriptions of the honey floras of the different states are also included in proper alphabetical order. In the case of the comparatively few plant species on which commercial beekeeping is dependent, extended descriptions are given of their distribution, time of blooming, nectar secretion, quality of the honey, and the conditions of soil and climate, under which nectar is secreted most freely. But many plants, which are of minor importance as sources of honey and pollen, but are helpful in stimulating broodrearing and in the support of the colony after the main honey-flow is over, are brought to the attention of beekeepers. Much new material has been added to this edition concerning honey plants previously described, and many new plants are discussed for the first time. The honey flora of the southwestern United States has received special attention. Most of the photographs are by the author, but a number have been taken from articles which have appeared in the American Bee Journal.—*J. H. Lovell.*

10984. PHILLIPS, E. F. Bees for the orchard. *Jour. Econ. Ent.* 23(1): 218-223. 1930.—The rapidly increasing demand for honeybees as supplementary pollenizing agents in orchards intensifies certain beekeeping problems. The more important are: Danger to bees from insecticidal dusts; the necessity of having strong colonies early in the spring; and the spreading of American foul-brood by possible movement of infected colonies by the careless or uninformed. Criteria for the evaluation of the rental value (for pollination) are discussed with a suggested value of $10 placed upon a colony containing 10 frames of brood (not eggs). Possible ways of using package bees for pollination are outlined.—*R. Hutson.*

10985. SOUDEK, ŠTĚPÁN. Hltanové zlázy vcely medonosné. (Apis mellifica.) [The pharyngeal glands of the honeybee.] [With English summary.] *Bull. École. Sup. Agron. Brno* 1927(C-10): 1-63. 3 pl., 15 fig. 1927.—A detailed cytological study of the pharyngeal glands*, tracing their histological development. These glands consist of 2 ducts to which many round compact bodies are closely attached. They lie in the head rolled up around the optical lobes of the brain. In young bees they are empty and small, but develop with feeding. Pollen-substitutes failed to cause proper development. The writer believes that the brood-food is prepared in these glands.

10986. STABE, HENRY A. The rate of growth of worker, drone and queen larvae of the honeybee, Apis mellifera Linn. *Jour. Econ. Ent.* 23(2): 447-453. 1930.—The maximum weight of worker larvae is attained between 114 and 122 hrs.; of queen larvae between 122 and 134 hrs., and of drone larvae between 164 and 184 hrs. The rate of growth of worker larvae varies greatly during a given instar, being greatly reduced just previous to, during, and after a moult. The rate of growth of worker and queen larvae is nearly identical during the first 48 hrs.—*F. B. Paddock.*

GENERAL

10988. BRÖDERMANN, E. A., und G. FREYER. Der Werdegang des deutschen weissen Edelschweines, seine Züchtung, Beurteilung und Verbreitung. Heft. 373. 88p. 51 fig. Deutsche Landwirtschafts-Ges.: Berlin, 1930.—The origin and development of the German Edelschwein, or white hog, is traced by periods since 1887 when the classifications used at swine shows of the German Agric. Society began to require increasingly purer breeding, resulting in a more uniformly superior type of hog exemplified by the present day Edelschwein. Show classes for individuals and groups are given for the successive yrs.; also a list of Edelschwein breeding associations in Germany that have fostered the improvement of this breed. Criteria for a utility type of hog are that it yield: (1) pig roasts of a high quality, (2) fresh smoked meat, sausage, and fresh meat for city demand, where pigs weigh from 90-110 kgm., (3) superior cuts of cured meat. These demands are held to be more easily satisfied by a medium large white Edelschwein than a larger heavier one, that would with difficulty combine size with a skeleton meeting these requirements of quality. The points of a hog, fancy, utility, body proportions, are described toward which the breeding program is directed. Extended pedigrees are given of noteworthy members of this breed of hogs. During the yrs. 1928 and 1929 boars and sows that were entered in the German Agricultural Society expositions had measurements taken of 8 body dimensions in addition to weight, which data have been tabulated.—*G. Bohstedt.*

10989. BÜNGER, H. Fütterungsversuche mit rohen Kartoffeln an Milchkühen. [With English summary.] *Tierernährung* 2(6): 467-481. 1931.—Fresh, uncut potatoes were readily eaten, with no ill effects on digestion and condition. The diminished volume of feed caused by substitution of 25 kgm. potatoes for 40 kgm. of beet-roots necessitated 1-2 kgm. of straw as a supplement. There were no differences in the palatability of the 2 varieties of potatoes used. When substituting 15 kgm. potatoes for 40 kgm. of beet-roots, milk-yield diminished a little (2.5% with the variety "Preussen," 5.2% with the variety "Pepo"). Milk fat decreased a little on feeding potatoes. The further diminution of milk fat after the feeding of potatoes was discontinued is supposed to be an unfavorable after-effect of feeding potatoes, but this cannot be positively affirmed. The effect of the 2 varieties of potatoes on the quantity of milk fat was the same. Feeding of potatoes had no more unfavorable effect on the condition of the cows than the feeding of beets. With regard to gains of weight, the variety "Preussen" seems to be a little superior to the variety "Pepo."

10990. ECKLES, CLARENCE HENRY, WILLES BARNES COMBS, and HAROLD MACY. Milk and milk products, prepared for the use of agricultural college students. 379p. 92 fig. McGraw-Hill Book Co., Inc.: New York, 1929. Pr. $3.50.—Although primarily a text

book for an introductory course in dairying such as is generally given to students during the 1st or 2nd yr., this book is sufficiently complete to give rather comprehensive and useful information about milk and milk products to readers who are not specializing in dairying. The authors discuss in detail the constituents of milk, its properties and the factors influencing the composition of milk. Considerable attention is given to bacterial development and its relation to milk. Discussions of the common dairy processes, cream separation, pasteurization and homogenization are included in one chapter. Separate chapters deal with such topics as market milk, butter, cheese, ice cream, condensed milk, dry milk and milk by-products. The application of simple mathematics to practical problems is shown by typical cases which arise in practical dairy operations. Specific directions for making the various tests of milk, cream and other dairy products are included. In addition to its use as a text the book should be valuable for reference purposes as well as a source of general information for anyone not engaged in the dairy industry who is interested in milk and the food products made from it.—*A. H. Kuhlman.*

10991. EDIN, H. Itaminfodrets smältbarhet och fodervärde vid användning till kalvar. [Digestibility and feeding value of "Itamin-feed" for calves.] [German summary.] *Kungl. Landtbruks-Akad. Handl. och Tidskr.* [*Stockholm*] 68(2): 164-183. 1929.—Tests are reported of "vitamin feed," a fat emulsion intended to be added to skimmed milk, as a substitute for butter fat in calf rearing. Experiments on digestibility were carried out according to the author's qualitative methods which are described in detail in report No. 309, of the Zentralanstalt. The preparation, of which the fat is said to consist of 90 parts soy-bean oil and 10 parts cod liver oil, showed the following average percentage composition: dry matter 97.1%, crude protein 10.1%, crude fat 68.1%, carbohydrate 16.0%, and ash 2.8%. The Itamin-feed was mixed with skimmed milk and water, 40-50 gm. of Itamin-feed and 820 gm. of skimmed milk included in each kgm. of artificial milk. When the daily feeding of this mixture was increased so that it could replace a still larger quantity of whole milk, digestive disturbances occurred when the quantity of Itamin-feed exceeded 300-350 gm. per 100 kgm. of live weight of the calves. The digestibility of the fat was slightly less than that of whole milk, being about 92-95% compared with 98.6-99.8% for the whole milk. In the present form therefore, the Itamin-feed is not a complete substitute for butterfat.—*Author's summary (transl. by J. L. Lush).*

10992. MARQUARDT, J. C., and A. C. DAHLBERG. The volume of the cream layers forming on Holstein and Jersey milk. *Jour. Dairy Sci.* 11(5): 409-419. 1928.—The comparative creaming properties of milk may vary according to the procedure followed in making the tests. For greatest uniformity and the exclusion of unknown factors the milk was set for creaming within a few min. after milking in ice water at 2.8°-4.4°C. The cream layers of different samples showed variations in the cream layer volume and the distinctness of the cream line after 2 or 4 hrs. which were less pronounced after 24 hrs. The mean depth of the cream layers forming on normal milk from Holstein and Jersey cows was directly proportional to the percentages of fat which they contained. The percentage which the cream layer represented of the total volume of milk was about 4.1 times the percentage of fat. The variations in the cream layer volumes forming on individual samples of Jersey milk were greater than those for Holstein milk. The difference was especially noticeable after 2 and 4 hrs. of creaming. The milk from an individual cow did not possess uniform creaming properties from milking to milking although there was a tendency for the milk from certain cows to give either large or small cream layer volumes or a high percentage of no layer cases. The cream layer volumes on the samples of milk used in these tests were not affected by the season of the yr. in which the milk was produced. The milk from Holstein cows remained most uniform throughout the yr. Variations in specific gravity of milk were not related to changes in creaming properties.—*Authors' summary.*

10993. ROADHOUSE, C. L., and G. A. KOESTLER. Contribution to the knowledge of the taste of milk. *Jour. Dairy Sci.* 12(6): 421-437. 1929.—The taste of milk, as this word is commonly used, is the sensation perceived when milk is taken into the mouth. The term "flavor," as used here, is a combination of the sensations of taste, perceived in the mouth, with those of smell, produced through the medium of the inner nasal passages. It has aided in precision to confine the term "taste" to those sensations which are perceived only in the mouth. The primary taste of milk has been designated as the sum of all of the taste impressions coming from normal milk, and not influenced by feed or the secretion of abnormal milk. The secondary taste includes that which is added to the primary taste from different sources, such as feed and products of disease. It is necessary to eliminate these secondary influences in order that primary tastes can be properly determined. The chloride-lactose relation is one of the most important bases of milk taste. Milk samples with a high chloride-lactose ratio were judged less favorably than those of like origin where the chloride-lactose ratio was low. The primary taste of skim milk is practically equal to that of the whole milk from which it is separated. By dialysis, it was possible to separate the milk into 2 parts (dialyzate and residue) with extreme differences in taste. Nearly all of the milk components producing the primary taste were present in the dialyzate, while the components remaining in the residue could be designated as free from taste. Dialysis shows, further, that fat and protein substances, as well as certain difficultly dialyzable salt components, which go to make up a large percentage of the milk content, take only a subordinate part in the primary taste of the milk. The dialysis of milk containing a pronounced feed taste showed that the feed taste was found very largely in the residue, and appeared to be either not dialyzable or combined with milk fat or with other non-dialyzable materials.—*Authors' summary.*

10994. WATSON, S. J. Investigations into the intensive system of grassland management. By the Agricultural Research Staff of Imperial Chemical Industries, Limited. IV. The digestibility and feeding value of artificially dried grass. V. The digestibility and feeding value of grass silage made in a tower, and the digestibility and comparative yield of artificially dried grass obtained from the same source. VI. The digestibility and feeding value of grass silage made in a stack. VII. The digestibility and feeding value of grass silage made in a pit. *Jour. Agric. Sci.* 21(3): 414-424; 425-441; 452-457; 469-475. 1931.—IV. Trials with sheep on a sample of dried grass and a grass meal, both artificially dried on an experimental band drier, showed that the digestibility of the 2 samples is high. The sheep gained weight during both trials and there was a retention of N and mineral matter. The dried grass apparently contains adequate available Ca, P and K for the plane of nutrition at which it was fed. The high digestible crude protein content and narrow nutritive ratio of the dried grass and grass meal prove the material to be superior to excellent hay despite the fact that both samples had a lower crude protein content than would normally be obtained under conditions of intensive treatment. A feeding trial with dairy cows in which most of the production ration was replaced by the dried grass showed that artificially dried grass was readily eaten and produced the quantity of milk for which the nutrients it supplied were theoretically capable.—V. Experiments showed that it is possible to make ensilage of high digestibility from grass in a tower silo. The loss by drainage is negligible and the losses due to fermentation are not high. All silage except the uppermost protective layer was eaten readily. The milk yield is not affected when the silage replaces the whole of the hay in the maintenance ration.

The artificial drying of grass results in the production of a material of high digestibility. The artificially dried grass from 1000 lbs. of fresh grass contains somewhat more starch equivalent and digestible crude protein, and considerably more digestible true protein, than the silage from the same amount of fresh grass.—VI. It is concluded from a trial that the making of stack silage is useful in conserving surplus grass, particularly of the aftermath type, when good haymaking weather may not obtain. Though no actual feeding trials were carried out with the silage, it was fed to stock with satisfactory results and formed a large proportion of their winter ration.—VII. Silage was made satisfactorily in a pit from grass cut at the flowering stage when it was impossible to make hay. The digestibilities of all the constituents compare favorably with meadow hay with the exception of the protein, which shows a depression. The silage is richer in starch equivalent than meadow hay if compared on a dry matter basis, and equal in digestible protein content to poor meadow hay though not to good meadow hay. It is therefore better to make grass silage when weather conditions are bad rather than attempt to make hay which, under such conditions, would be of poor quality. The silage was used within 4 weeks of being made and was eaten readily by dairy cows on grass.—*From author's summaries.*

10995. **WOOD, T. B., and L. F. NEWMAN. Beef production in Great Britain.** 67p. 1 pl., 13 fig. R. Silcock & Sons, Ltd.: Liverpool, 1928.—The beef cattle situation of Great Britain is discussed in a concise manner. Statistics of, and general system of beef production on, pasture and in dry lot, are given. For indoor feeding, home-grown roughages and roots are made use of extensively, together with the minimum of required protein concentrates. The margin of profit from beef production is frequently narrow, but other considerations, especially the production of manure, warrant a continuation of beef production on many farms. Possible increases in returns are pointed out by improvement in quality, by organization in the matter of store or feeder cattle movements, by baby beef production and intensive grassland culture. Baby beef production is limited through the fact that it requires about twice as much expensive concentrated feed for each pound of beef produced, as compared with 3-year-old beef which utilizes pasture to better advantage. Cambridge investigations extending over 3 yrs. are reported presenting data of standard cuts from beef cattle of known age and feeding. Each of 14 cuts was weighed and dissected into lean, fat, bone and waste. Each item was analyzed with respect to protein, fat and water after having been reduced to pulp in a rotary cutting machine. A detailed account is given of the methods used. The results obtained are presented in tables of composition of carcasses and cuts from animals of different types.—*G. Bohstedt.*

10996. **WOODMAN, H. E., A. W. MENZIES KITCHIN, and R. E. EVANS. The value of tapioca flour and sago pith meal in the nutrition of swine.** *Jour. Agric. Sci.* 21(3): 526-546. 1931.—Feeding trials (the ration of the bacon pigs from 140 lb. liveweight to slaughter included 40% of tapioca flour) confirmed earlier conclusions that tapioca flour exerts a favorable influence on the color and texture of the carcass fat and on the quality of the bacon. Sago pith meal may be introduced into the rations of bacon pigs, as a substitute for barley meal, up to 20% of the ration without depressing the rate of gain of live-weight. If the replacement is increased to 40% of the ration, the effect of sago pith meal is distinctly less than that of barley meal. Digestion trials suggest that the apparent lowering of the efficiency of sago pith meal as the amount in the ration is increased beyond 20% is due to a depressing influence which it exerts on the digestibility of the other foods in the diet, particularly the protein. Sago pith meal appears to contain no digestible protein; plus a small allowance of bran it has been found an efficient substitute for middlings for bacon pigs of more than 100 lb. live-weight, provided the sago pith meal amounts to not more than 20% of the ration. Of 29 carcasses from pigs given rations containing sago pith meal in partial replacement of barley meal, 27 were graded as "prime."—*Authors' conclusions.*

10997. **ZORN, W., und K. RICHTER. Ersatz von Vollmilch durch Itaminmilch bei der Ernährung der Kälber.** *Mitteil. Deutsch. Landw. Ges.* 44(25): 567-569. 1929.—Ten calves were raised on a ration in which Itaminmilch was substituted for ¾ of the whole milk. Slaughter data were obtained upon 3 of these calves. According to their appearances while growing up, their growth in weight, and the slaughter results, this method was satisfactory. 6 control calves were grown on whole milk. The change from whole milk to Itaminmilch was made gradually beginning at 7 days of age. The investigators find no objection to the use of this preparation in feeding animals which are to be slaughtered. At prevailing prices a distinct saving can be effected by its substitution for whole milk. Caution is to be observed in applying these results to calves intended for breeding purposes since there has not yet been any experimental test of whether this treatment will influence the future production of animals so reared.—*K. E. Ferber (transl. by J. L. Lush).*

POULTRY

10998. **ARNDT, MILTON H. Battery brooding. A complete exposition of the important facts concerning the successful operation and handling of the various types of battery brooders.** 323p. 74 fig. Orange Judd Publ. Co.: New York, 1931. Pr. $2.00.—The principles of feeding and of battery brooder operation including the factors, temp., ventilation and humidity as well as the various uses and limitations of battery brooders, are discussed. Suggestions are given for building and equipping battery rooms. Various commercial makes of batteries are described. Suggestions are also given for the prevention and remedy of such difficulties as cannibalism, crowding, poor feathering and hock trouble.—*L. E. Card.*

10999. **GÜNTHERBERG, KLAUS. Versuche über die Fettverdauung beim Huhn.** *Wiss. Arch. Landw. Abt. B. Tierernähr u. Tierzucht.* 3(2): 339-367. 1930.—As the present knowledge of fat digestion in fowls is contradictory the digestibility of nutritive fat by hens was studied. Natural fat and pure fat (neutral fat and cholesterol) were determined both in the food and in the excrement. Trials were made with 12 hens. By feeding very little fat an increased excretion of fat in proportion to the intake was obtained, but this could not be detected after about 8 days. Evidently the presence of crude fat and ether-soluble substance in the feces indicates fat cleavage by the intestine or by bile. The amounts of these 2 kinds of fat were greater with larger intakes of fat, but with smaller doses were too small to be considered as separate factors. These experiments show that the hen is well able to digest fat. Since it has been shown that fat cleavage occurs in the small intestine, one must assume the presence of an intestinal fat-splitting enzyme. Of the cereals the fat of maize is the most digestible, that of oats next, with barley and wheat fats less so. In crushed cereals the fat is somewhat more digestible. The differences in digestibility are attributed to different melting points of the fats. The digestibility of fat increases somewhat if the feed becomes insufficient for maintenance, and the reverse is true with more generous feeding. Abnormal fat excretion occurs in sick birds. By adding rape seed to oats and maize the optimum efficiency of digestion and a maximum fat ingestion of 4.7 gm. fat daily was obtained. After this optimum was exceeded, there was a fairly proportionate decline in digestibility. When meat meal is added to barley in small amounts digestion of its fat is almost complete, and the digestibility of the barley fat is increased in comparison with its utilization when barley is fed alone. With larger doses this favorable effect declines until digestibility is reduced below the

original level, although the amount of fat contained in the basal ration also plays a part. By comparing the coefficients of fat digestion in single feeds by fowls, swine and cattle, it is concluded that hens are not inferior in ability to digest fat but are actually better able to digest the fat of certain feeds.—*Author's summary (transl. by F. B. Hutt).*

11000. SCHMIDT, J., und J. ZÖLLNER. Über den Einfluss des Alters der Hennen beim Legebeginn auf Eigewicht, Eierproduktion und Körpergewicht. *Züchtungskunde* 5(8): 352-356. 1930.—In studies with 270 White Leghorns hatched in 1927, and 137 hatched in 1928, it was found that almost half of all the birds began to lay at 22-25 weeks of age. The later the fowls began to lay, the greater was the average weight of the first 10 eggs and of those for the whole 1st yr. production. The maximum egg weight attained was independent of the age at 1st egg. The earlier the birds began to lay, the greater was the total production in their pullet yr. Age at 1st egg had no significant effect on body weight of the fowls.—*E. Lauprecht (transl. by F. B. Hutt).*

11001. SHEEHY, E. J. The optimum concentration (starch equivalent) of the meal mixture for chickens and growing pullets fed an all-mash diet. *World's Poultry Congress* 4(Sect. B): 255-261; résumé sect., 31-32. 1930.—Week-old chicks were divided into 4 groups and fed an all-mash ration which varied in bulk and concentration in the different groups. The starch equivalents per 100 lb. of the mixtures were 56, 60, 63, and 66 respectively. The rate of growth of the chickens increased progressively as the concentration of the mash was raised; and the weights of the birds after 12 weeks on experiment, especially of the cockerels, showed definitely the advantage of the most concentrated mash fed. The weights of the pullets from the 4 groups suggested that, with pullets as with chicks, there is an optimum mash for the production of greatest weights; in this experiment the highest concentration of mash did not exceed the optimum. The more concentrated mash conduced to greater egg production in the pre-winter period than did the less concentrated one. Early production is desirable provided it does not interfere with the growth of the pullet or with the ultimate size of egg, and provided also a temporary early winter moult is not thereby induced. Conceivably the consumption of a mash which contains the optimum starch equivalent, that is which provides for the maximum intake of nutriment, would provide for extensive production and at the same time promote normal growth in the adolescent pullet, thus preventing the adverse consequences of early sexual development.—*Author's summary.*

11002. TITUS, HARRY W., and WALTER A. HENDRICKS. The early growth of chickens as a function of feed consumption rather than of time. *World's Poultry Congress* 4(Sect. B): 285-292; résumé sect., 35. 1930.—In 2 experiments, in which several pens of chicks were fed at different levels of feed-intake, it was found that up to about 1 lb. or even somewhat more, the average live-weight of the chicks in all the pens could be considered a function of feed consumption alone. A possible explanation is that the maintenance requirement of the young growing chick is only a small fraction of the total amount of feed consumed. It is desirable, when comparing 2 or more diets for growing chicks, to feed them at the same level of feed-intake, even if this level is appreciably lower than the "normal" level. In cases where the feed consumption is not the same, a comparison of the diets should be made by plotting the live-weights against feed consumption.—*Authors' résumé.*

11003. WAITE, ROY H. Poultry science and practice. ix+433p. 337 fig. McGraw-Hill Book Co. Inc.: New York, 1929. Pr. $3.50.—This is a practical treatise on poultry raising and the marketing of poultry products. The first 18 chapters are devoted to the various phases of the chicken industry; Chap. 19 is devoted to turkeys, ducks, and geese; Chap. 20 is devoted to domesticated game birds. There is a useful appendix.—*M. A. Jull.*

11004. WIERZCHOWSKI, ZENON. O czynnikach strawności sktadników pokarmowych u ptactwa domowego. [Factors influencing the digestibility of foodstuffs in poultry.] *Pamiętnik Państ. Inst. Nauk. Gospod. Wiejskiego w Puławach* 9(2): 388-462. 1929.—The quantitative composition of N in the urine of fowls and pigeons being almost identical, Katayama's equations can also be applied to investigations on foodstuff digestibility in pigeons. The principal components of wheat, wheat-flour and bran were assimilated to almost the same degree by pigeons as by fowls. The digestibility of crude wheat protein in fowls varied from 81.3-87.4%; average 84.1%; in pigeons the range was from 75 to 85%, average 79.43%. An average of 90.2% wheat carbohydrates was digested by cocks and 87% by pigeons, with small variations from 88.4 to 91.3% and from 85.6 to 90.1% respectively. The cocks digested from wheat bran 57.6% of protein and 66.2% of carbohydrates, the pigeons 56.4 and 64.4% respectively. Wheat flour as the only food was usually well utilized by both fowls and pigeons. The coefficient of crude protein for fowls and pigeons had the same average value 80, whereas the coefficient of carbohydrates was in pigeons 93.15, in the cock 95.30. In comparison with mammals, fowls and pigeons did well on the principal wheat components. With wheat meal the only food, the digestibility of carbohydrates is several percent higher in fowls than in pigeons. Improvement of mechanical digestion in pigeons and fowls had no effect on the digestibility of carbohydrates and proteins of wheat. Digestibility of fat, on the contrary, was much higher in ground than in entire grain. Drying wheat at 120° C. greatly reduced the digestibility of crude protein. Neither fowls nor pigeons profited from crude fibre, but eliminated it after different intervals, during which a certain amount of digestibility in certain periods and a negative one in others was ascertained. In pigeons the lack of vitamine B in the food-stuff had no direct or indirect influence on the digestibility of food. Feeding with wheat devoid of vitamines for 2 months did not impair digestion. Dried wheat deprived of vitamines, and especially its protein, was less digestible than normal wheat, which is attributable to desiccation, not to absence of vitamines, and the addition of vitamine extracts did not improve its digestibility although it cured sick pigeons and induced increase in body weight. Forced feeding did not impair the digestibility of the principal components. Each foodstuff applied separately was, as a rule, digested in a different manner than mixed feeding stuffs. When 2 foodstuffs were mixed the digestibility of protein and carbohydrates underwent considerable changes. Mixing 2 foodstuffs of low coefficients of digestibility may produce a well digested food. The fowls fared worse or better on the same foodstuff applied in several different mixtures, according to the nature of the 2nd component of the mixture; e.g., bran with wheat, bran with meal, potato starch with wheat, potato starch with bran, casein with wheat, casein with meal. In consideration of this the coefficients of digestibility of a certain foodstuff, which have been obtained in experiments with one combination only, can not be applied without qualification when administering the foodstuff in various combinations. The digestibility of albumin from animal origin reached 100%, and this albumin improved the digestibility of plant protein. Vegetable albumin (pure gluten) was poorly digested. Clover hay fed alone was of little value, but improved the digestibility of foodstuffs in mixtures. Pure potato starch was poorly digested regardless of the composition of the food mixture. This low digestibility is due neither to the softness of this starch nor to the lack of amylolytic enzymes. The coefficient of digestibility of potato starch can be raised from 30 to 59% by increasing the crude fibre content. —*From author's summary.*

CROP SCIENCE (ARVICULTURE)

11005. MENDEZ, CARLOS TEIXEIRA. Cultura do arroz. [Rice culture.] *Rev. Agric.* [*São Paulo*] 5(7/8): 275-284. 1930.—The author made a comparative and experimental study of 3 principal varieties of rice cultivated in São Paulo (Brazil). The variety "Dourãdo" produces a product of higher quality than the others. On less moist and less fertile soils it is preferable to any other variety. For very favorable conditions, the variety "Jaguary," also gives a good product. As evidence of the advantages of selection, yields of more than 4000 Hilos net per ha. without any artificial fertilizer are noted.—*C. T. Mendez (transl. by L. Gano).*

11006. [ORLOV, A. A.] ОРЛОВ, А. А. Ячмени Абиссинии и Эритреи. [The barleys of Abyssinia and Eritrea.] [English summary.] Труды по прикладной Ботанике, Генетике и Селекции (*Bull. Appl. Bot., Genet. and Plant-Breed.*) 20: 283-345. 31 fig. 1929.—The barleys of Abyssinia and Eritrea represent a sharply marked ecological group strikingly different from others of Asia and Europe. The most characteristic features are: a long tillering period; increased tillering; long, narrow leaves of milky green color; a trapezoid-shaped ligule; open flowering and elongated large grain, the weight of 1000 grains being 50 gm. and more. The chief varieties of many-rowed and 2-rowed barleys occur, as well as greatly varying forms of subsp. *intermedium* Körn. The many-rowed barleys, *Hordeum vulgare*, are represented by varieties of the *pallidum, parallelum,* and *pyramidatum* groups; and the 2-rowed barleys (*H. distichum*) by *nutantes, deficientes, erectum,* and *zeocritum*. In these groups are found varieties: (1) hulled and hull-less; (2) with narrow and with broad empty glumes; (3) with dentate and with smooth awns; (4) with grain of yellow, black, green and purple color. Curious anomalies also occur, e.g., the main ears of a plant show characters of one variety, while the other ears of the same plant exhibit characters of another variety. Variations have been noted as follows: (1) the main ear with smooth awns, other ears with dentate awns; (2) the main ear with dentate awns, the other ears with smooth awns; (3) the upper part of the ear characteristic of var. *parallelum,* the lower var. *pallidum;* (4) the main ear, characteristic of var. *parallelum,* the other ears, var. *pallidum;* (5) overlapping varieties with regard to density and ear shape are met with, as *pallidum-parallelum, coeleste-revelatum.* Abyssinia and Eritrea constitute one of the main centers of distribution of the forms or varieties of *H. sativum;* 38 varieties were found (34 in Abyssinia, 19 in Eritrea, 15 common to the 2 regions), of which 19 are endemic (15 for Abyssinia, 4 for Eritrea). The following new varieties of *H. sativum* are described: From Abyssinia, **aethiopicum*, amaricum*, djimmaicum,** and **asmaricum*** (also in Eritrea); from Eritrea, **glabriparallelum, erythraeum*,** and **meneliki.** Abyssinia is the principal center of origin and diversity of the varieties: *pallidum, nigrum, nigripallidum, duplinigrum, deficiens, steudeli,* and *abyssinicum.* From here these varieties have spread far beyond the limits of their native country. The hull-less barley varieties of Abyssinia, as *coeleste, revelatum, sublatiglumatum* and *nudideficiens* differ sharply as to their morpho-physiological characters, from the same varieties occurring in Asia. The hull-less barleys of Abyssinia are, in all probability, of a different genetic origin than those of Asia. In Abyssinia and Eritrea, barley is grown at an altitude of 1800-3000 m. The varieties of 2-rowed barley are grown chiefly in agricultural regions of less altitude. They do not occur higher than 2400 m. Hull-less barley is chiefly grown on mountain plateaus at an altitude of 2800-3000 m. The same distribution may be recorded for the different forms of the subsp. *intermedium,*—Abyssinia and Eritrea (the latter in a lesser degree) being the chief geographical center where the whole diversity of its different forms may be found. These barleys of Abyssinia and Eritrea are characterized by strong straw, absence of lodging, and under field conditions are relatively immune from mildew and different species of rust. Early forms occur. In semi-humid and dry regions they show a high protein content, 20% or more, while in moist regions e.g., the Western and North-Western regions of U.S.S.R., the protein content is low. —*Adapted from author's summary.*

SOIL SCIENCE (EDAPHOLOGY)

11007. ALBRECHT, WM. A., and E. M. POIROT. **Fractional neutralization of soil acidity for the establishment of clover.** *Jour. Amer. Soc. Agron.* 22(7): 649-657. 2 fig. 1930.—Field trials of amounts of lime as small as 300 lb. of 30-mesh material per acre combined with inoculated soil and drilled with the clover seed demonstrated by trials of 3 yr. that this treatment was as effective as 5,000 lb. of 10-mesh limestone broadcast for establishing the clover crop on a lime-deficient soil (Gerald silt loam). The use of small amounts of fine lime drilled with the seed was effective in establishing both red and sweet clovers. On account of defective sweet clover seed, this crop was included in only 2 yr. of this study. The fine lime produced crops of sweet clover as good as those produced by the heavy applications of the 10-mesh stone, while the crops of red clover were usually superior under the treatments with the 30-mesh stone. The use of the finer lime hastened the development of thorough inoculation on the roots of the clovers and served to establish them more quickly through this aid on this soil of depleted fertility. The results of this study raise doubt as to whether it is necessary to neutralize completely the acidity of the surface soil for the successful growth of clover and suggest that it may be necessary to provide only certain limited areas of limed soil accessible to the clover roots.—*Authors' summary and conclusions.*

11008. **BRÜNE, F. Grundzüge der Regelung der Wasserwirtschaft bei Moorböden.** *Mitteil. Vereins Förder. Moorkultur Deutsch. Reiche* 48(10): 173-181. 1930.—Plants can not thrive in marshy soils because of the presence of excessive amounts of water and lack of O. If drained too much the soil loses its power to absorb water. In the flat northwestern plains of Germany the virgin meadows are drained to a depth of 40-50 cm., the pastures 60-70 cm. and cultivated land 70-80 cm. On high marsh lands deeper drainage is more dangerous than on low lands because in the former a strong root zone exists at a depth of 20-25 cm. In dry summers the level of the water must be raised and capillary action must be maintained by rolling the ground surface. The frequency of drainage depends upon the depth of the bog, its flora, the permeability of the upper peat strata and upon the nature of the surroundings. Drainage by open ditches is preferred. Where the ground surface is too dry a top dressing of sand or a sand mixture is recommended.—*F. Brüne (transl. by F. F. Halma).*

11009. **GOY, S., P. MÜLLER, und O. ROOS. Über das Verhältnis von leicht und schwer mobilisierbarer Säure in der Bodenzone der Austauschsäure und die Bedeutung des Pufferungswertes für diese.** *Zeitschr. Pflanzenernähr*

Düng. u. Bodenk. A, Wiss. Teil. 18(2): 104-114. 1930.—In the course of the work the pattern or form and the relative mass of the base holding space of a soil is constructed. The proportion of easily soluble acid and that which is soluble with difficulty in the realm of the replaceable acid is determined for different kinds of soil, and it is shown that in organic soils, below pH 5.5, much more of the acid that is soluble with difficulty comes under the head of replaceable acid than is the case with mineral soils. An absolute exchange value is constructed for each soil. This exchange value is employed for the differentiation of mineral soils from organic or humus ones. This exchange value limits the employment of the electrometric titration method for the determination of exchangeable acid to mineral soils of normal constitution, those soils lying outside these limits to be treated as organic or humus soils.—*Authors' summary (transl. by J. H. Barron).*

11010. **GRADMANN, HANS. Untersuchungen über die Wasserverhältnisse des Bodens als Grundlage des Pflanzenwachstums. II.** *Jahrb. Wiss. Bot.* 71(5): 669-782. 14 fig. 1929.—The author states that most previous methods for the determination of the mobility of water in soils have been very inefficient. The author used evaporation methods. In one case a U-tube containing water was attached to a tube filled with soil. In another series of tests the soil was placed in a glass tube, about 80 cm. long with cross sectional area approximately 2 sq. cm., which was placed perpendicularly with the lower end resting in the center of a closed cylindrical glass vessel about 3.5 cm. in diam. The upper end of the tube passed through the stopper of an inverted similar glass vessel. The bottom of the lower vessel was covered with a shallow layer of dist. water and the inner wall was lined with moist filter paper. The upper glass vessel was filled with $CaCl_2$ up to the top of the tube which terminated in the center of the vessel. In a 3rd series of tests a specially designed metal desiccator was used, $CaCl_2$ being the absorption medium. In this case the various soils were each tested in tubes of different lengths. In addition to these methods the rate of evaporation from soils in open glass tubes 10 cm. long, placed in the open air or in drying chambers, was compared with the rate of evaporation from an evaporimeter having a similar-shaped evaporation surface. By the methods used it is stated that a constant suction or absorption force was being exerted on the soils at all times, thus making possible the measurement of the mass of water that passed a unit of distance in a given unit of time. It is maintained that by these methods the exact rate of movement of water toward the root can be more accurately determined.—*E. T. Bartholomew.*

11011. **LEMMERMANN, O., W. JESSEN, H. ENGEL, H. BORTELS, v. SCHMELING, und W. LESCH. Die Bedeutung des Kohlenstoff-Stickstoff-Verhältnisses und anderer chemischen Eigenschaften der organischen Stoffe für ihre Wirkung.** *Zeitschr. Pflanzenernärch. Düng. u. Bodenk. A. Wissensch.* 17(6): 321-355. 1930.—Through the decomposition of organic matter in the soil, both the chemical and biochemical action of the soil is changed. The physiological value of a substance depends upon (a) the C:N ratio, (b) the N content, (c) the degree of humification, and (d) the pentosan content. The determination of the energy content of an organic substance merely by measuring the CO_2 production leads to unsatisfactory results. When such research is undertaken with microorganisms, one must be sure that enough N is present for their nutrition. If the C:N ratio in organic substances (straw, etc.) is kept at 20:1 or less, the decomposition of the substance is so advanced that there is a loss of about 50% of the dry substance. In this case the N content of the organic substance is generally 2% and more. The injurious action of such organic substance ceases when the C:N ratio is about 20:1 and the N content is 2% or more of the dry substance. The degree of humification (as determined by the NH_3) seems to be more than 30%. The pentosan content of such organic materials is less than 12%. An experiment carried out in the laboratory under a given light exposure in the winter showed that a fairly advanced degree of decomposition of straw or straw manures is necessary to eliminate its N-fixing action. This should be considered more in field practise, since straw is often placed on the ground in spring in a very unsatisfactory stage of decomposition, to be of value. With this fertilizer, N fertilization can never give complete satisfaction.—*Author's summary (transl. by M. A. Joslyn).*

11012. **McLEAN, W. The carbon-nitrogen ratio of soil organic matter.** *Jour. Agric. Sci.* 20(3): 348-354. 1930.—The average C/N ratio for 50 British soils from widely distributed areas approximates to the figure 10:1 given by other investigators. The range of variation is from 6.5 to 13.5:1. 16 foreign samples gave C/N ratios varying from 2.0 to 23.0:1. Soils from limited areas, whether high or low in organic C, give approximately constant ratios, but these ratios vary from place to place according to soil, climate, etc. It is suggested that the C/N ratios may be specific. The C/N ratios of arable soils do not differ appreciably from those of grassland soils. The percentages of C and N are somewhat higher in soils of high fertility than in poor soils in the same area. The author suggests that the total organic C or the total N might be used as an index of fertility in the examination of crop-bearing soils in the same area. For routine work, the C determination is to be preferred both for rapidity and ease of manipulation. The C/N ratio decreases in descending a profile. The high ratio in the top layer is, no doubt, due to the presence of plant remains.—*Author's summary.*

11013. **MALHERBE, I. de V. Some outstanding facts relating to the fertility of South African soils.** *So. African Jour. Sci.* 26: 125-130. 1929.—This is a brief review, very general in scope. The rainfall distribution and the origin of the principal soils are noted. Grain soils are generally in need of P but not K, except the sandy soils of humid areas. N is needed but not over 10 lb. of available N per acre should be used, due to the high straw:grain ratio resulting. Mild acidity, limited benefit and relatively high price restrict the use of lime. Water shortage is the most limiting factor. The author recommends that (a) grain soils should not be plowed too deeply, and (b) the plow be discarded in favor of the spring tooth cultivator in preparing the seedbed of summer fallowed lands. Orchard and vineyard soils are much more diverse in character. Conservation of moisture is esential. P, K and, where needed, lime should be applied regularly in autumn. Quick acting N fertilizer is urged where N is needed. A good cover crop is essential and the common "glousblom" (*Cryptostemma calendulaceum*) is recommended.—*H. A. Lunt.*

11014. **MOOERS, C. A. Some observations from liming investigation.** *Science* 71(1830): 81-84. 1930.—This is a report of work at the Tennessee Station on the effects of lime on certain chemical changes in the soil. The shallow tank lysimeter has been used in these tests, and for this purpose is considered superior to lysimeters which include subsoil. Liming with burnt lime accelerated the drainage loss of N and the oxidation of humus for a few years, after which there was little difference between the limed and unlimed soil. When 2 tons of burnt lime were used maximum carbonation took place within 5 days and complete silication within 10 days. Mg carbonate was converted to silicate even more rapidly than was $CaCO_3$. The general conclusion is drawn that the effects of an ordinary liming with burnt lime are derived primarily from silicates. Silicates of Ca and Mg produced greater clover crops than their corresponding carbonates. Light applications of lime accelerated the outgo of SO_4. Heavy applications of burnt lime retarded the outgo. Liming was found to depress the liberation of K. Liming increased the outgo of Ca and depressed the outgo of Mg. Mg oxide or carbonate increased the loss of Mg, but depressed the Ca loss. The author believes that the soil solution is the source of all the nutrients taken up by the roots of plants. In this case lysimeter findings

should be of much value in determining the effects manurial treatments are likely to have on plant nutrition.—*F. L. Duley.*

11015. NĚMEC, ANTONÍN. Über den Einfluss löslichen Kieselsäuregehalts der Böden auf die Resorption der Phosphorsäure durch die Pflanze. *Biochem. Zeitschr.* 190 (1/3): 42-56. 1 fig. 1927.—The amount of soluble silicic acid in different soils was estimated by extracting 30 gm. of soil with 100 cc. of water for 1 hr. 3 types of soils were used: (1) clay and loam-containing clay; (2) clay-containing loam and loam; (3) clay-loam containing sand and sand. The amount of soluble silicic acid decreases with decrease of clay. Heavy clay-containing soils do not show an optimum capacity for the liberation of soluble silicic acid. Clay-containing loams and loams consisting of 80-90% of soil granules under 0.05 m. diam. give off the largest amounts of soluble silicic acid. In clay-containing sand soils and loamy sand soils, the silicic acid decreases with the increase of sand. Therefore, the finer particles (0.1-0.05 mm.) of the loam-containing soils are the main source of silicic acid. Most soils containing 40-50% granules of this size contain sufficient soluble silicic acid except the heavy clay soils. If lime is added a decrease in soluble silicic acid can only be observed if it is added in large quantities and then only after 14 days. If soils are partly dried, the solubility of both phosphoric and silicic acid is increased. A soil extracted several times with water, after drying and again keeping moist for 14 days, contains the original amount of silicic acid. The influence of the presence of soluble silicic acid in the soil on the phosphoric acid assimilation was tested on growing rye plants. Those grown in soils of highest silicic acid content contain the largest amounts of phosphoric acid. Plants grown in soil poor in silicic acid show a negative phosphoric acid absorption. Only ionized silicic acid is considered. The effect of complex silica compounds is not known.—*M. G. B. Brandwijk.*

11016. PAASCH, E. Veränderungen der Bodenazidität unter besonderer Berücksichtigung der Heinrichauer Böden. *Zeitschr. Pflanzenernähr. Düng. u. Bodenk. B. Wirtsch. Prakt. Teil* 9(7): 309-326. 1 fig. 1930.—Determinations on 35 fields were made twice during a period of 2-4 yr. Since each field was divided in approximately 6 individual plots, the data consist of determinations from about 300 soil areas. The maximum change was about 1.0 pH to the acid or alkaline side. The acidity changes were not arbitrary, but on a series of fields of the same soil type and weathering conditions, varied with the addition of organic or inorganic fertilizers. The following conclusions are given: Fields limed during the interim became more alkaline; increase in alkalinity with liming, but without green manuring, was about 0.9-0.4 pH greater than with green manuring, in which case it was 0.3-0.0 pH. A heavy green manuring causes acidification which can be neutralized by about 3-4 zentners caustic lime per ¼ ha. on the above soils. If liming occurred shortly previous to the final sampling so that secondary effects were still present, the soils maintained their acidity level. If lime was applied early the soils became appreciably more acid. If the soils received alternating physiologically acid and alkaline fertilizers, soil acidity increased 0.1-0.5 pH during this period. With only physiologically acid fertilizers, the acidity increase was greater. With green manuring in addition to alternating additions of physiologically acid or alkaline fertilizers, the increase in acidity was 0.6-1.0 pH. Stable manure produced no acid formation.—*Author's summary (transl. by O. C. Magistad).*

11017. BEAR, P. K. (edited by A. J. MACSELF). Simple fruit growing. 130p. Illus. W. H. and L. Collingridge, Ltd.: London, 1930. Pr. 2s. 6d.—This book is written from the standpoint of the English gardener as indicated by discussions of insects and diseases and varieties of fruits common to English gardens, and the detailed treatment of dwarf trees and wall and garden training. Designed primarily for the amateur and small home gardener, it is characterized by simple exposition and explanation of vital points often overlooked in treatises on fruit culture.—*H. B. Tukey.*

11018. BRISCOE, T. W. (edited by A. J. MACSELF). Orchids for amateurs. 138p. Illus. W. H. & L. Collingridge, Ltd.: London, 1930. Pr. 5s.—Out of long experience as an orchid grower, the author has produced a book especially for amateurs. Part I, of 66 pages, is devoted to general questions of housing and culture, including temp., ventilation, watering and atmospheric moisture. Emphasis is placed on maintaining hygienic conditions in the control of pests and diseases. Propagation, hybridization, and seed handling are fully discussed. A section deals with the classification of orchids into species and varieties, and illustrations facilitate the recognition of the principal genera and some of the important varieties. The book is designed mainly for English conditions.—*T. H. McHatton.*

11019. CHEVALIER, AUG. Les caféiers du globe. Fascicule I. Généralites sur les caféiers. (Encyclopédie Biologique V.) 196p. 32 fig. Paul Lechevalier: Paris, 1929.—This volume discusses the origin of coffee and the beginning of its use and commerce; culture of coffee in the 18th century, especially in the French Colonies; coffee from the botanical and biological points of view and the principles of tree culture applicable to coffee trees.

11020. COUTTS, J., A. EDWARDS, and A. OSBORN. The complete book of gardening. 768p. 96 pl. (16 col.) 65 fig. Ward, Lock & Co.: London, 1930.

11021. COX, E. H. M. Wild gardening. 124p. Illus. Dulau & Co., Ltd.: London, 1929.

11022. DAKERS, J. B. (edited by A. J. MACSELF). Simple greenhouse management. 130p. Illus. W. H. and L. Collingridge, Ltd.: London, 1930.—This is a concise, practical book for the amateur and small gardener. Although directed to the increasing number of English suburban gardeners who are adding small greenhouses to their equipment, it contains much information which may be applied to American conditions. It discusses small greenhouses with and without heat, greenhouse culture of vegetables and flowering plants, and propagation in general.—*H. B. Tukey.*

11023. DARNELL, A. W. Orchids for the outdoor garden. A descriptive list of the world's orchids that may be grown outdoors in the British Isles, for the use of amateur gardeners. xx+467p. 22 pl. L. Reeve & Co., Ltd.: Ashford, Kent, 1930.—This gives concise botanical descriptions, comments from the horticultural standpoint, habit notes, and cultural suggestions for 977 spp. For numerous spp. not yet under cultivation, the probable cultural requirements are deduced from what is known of their natural behavior. Species illustrated are *Calypso bulbosa, Acianthus caudatus, Brownleea caerulea, Caladenia patersonii, Caelogyne corymbosa, Cypripedium montanum, Disa cooperi, Diuris sulphurea, Eulophia hians, Gastrodia sesamoides, Habenaria tetrapetala, Holothrix orthoceras, Liparis liliifolia, Ophrys speculum, Orchis provincialis, Pleione hookeriana, Pogonia ophioglossoides, Pterostylis obtusa, Satyrium membranaceum, Serapias cordigera, Thelymitra longifolia.* Rank as "probably the finest and most

desirable of all the hardy Orchids" is given to the moccasin flower, *Cypripedium reginae*.—*S. S. Berry.*

11024. **DILLISTONE, GEORGE (compiled and edited by). Dykes on irises. A reprint of the contributions of the late W. R. Dykes, L-es-L., to various journals and periodicals during the last 20 years of his life.** 294p., Portrait. 18 pl. C. Baldwin: Tunbridge Wells, England, 1930. Pr. 21s. 6d.—This reprint of contributions made to journals and periodicals opens with a brief account of Dykes' life and works. Besides detailed notes on species and hybrids, the origin, raising, diseases, cultivation, hybridization, and classification of irises are treated.—*G. M. Tees.*

11025. **DODE, L.-A. Enquête sur les effets des froids de l'hiver 1928-1929.** *Bull. Soc. Dendrol. France* 1930 (73, 74): 10-23; 39-46. 1930.—All the injurious effects of heavy freezes are noticeable only after the passage of considerable time. The effects of the winter of 1928-29 could not be definitely estimated until the autumn of 1929, when the September drought aggravated the frost injuries. In some cases plants which were apparently lost began to sprout again vigorously from the base. The reports from different parts of France give in detail the species which survived and those which were more or less injured or killed.—*A. Rehder.*

11026. **EWERT, RICHARD. Blühen und Fruchten der insektenblütigen Garten- und Feldfrüchte unter dem Einfluss der Bienenzucht.** 150p. 48 fig. J. Neumann: Neudamm, 1929.—The author describes the pollination of numerous garden and field plants. The 1st part of the book deals with pollination and fertilization in general and with the methods of research; the 2nd gives particulars of the floroecology of the more common fruit trees, berry bushes, grape, strawberry, cucumber, and various field crops such as clovers, alfalfa, vetch, lupine, and others. A brief account of the wind-pollinated hazelnut, chestnut, and walnut is included. The pear may be taken as an illustration of the method of treatment: A discussion is given of the flower structure and manner of pollination, the results of crosses between different varieties, the percentage of fertility, the blooming time of different varieties and the effects of frost, insects and other factors on the production of viable seed. A bibliography is included.—*J. H. Lovell.*

11027. **FRANÇA, CARLOS. Subsídios para a história de algumas plantas cultivadas. [Further evidence on the history of some cultivated plants.]** 63p. 9 fig. Araujo y Sobrinho: Porto, 1928.—From a study of Portuguese and other writers of the Renaissance period the author has found new evidence on the origin and dispersal of 11 cultivated plants. The sweet potato is native to America and was introduced into Africa by the Portuguese as shown by the records of Gandavo, Anchieta, Oviedo, de Soto, and Ficalho. The potato, native of Chile, spread to Colombia before the discovery of America and appeared in Italy about 1587, spreading thence through central Europe (Clusius). Raleigh introduced it into Ireland from the Antilles, not Virginia (Bauhin, Strachey). It was not cultivated in Portugal until after the 17th century, probably due to its being considered poisonous (Bauhin). Tobacco was introduced into Portugal by Luis de Goes and appeared in Spain about the same time. Nicot brought it to France from Lisbon, not directly from America. The cashew was first described by Thevet in 1558. Anchieta, Gandavo and Cardim also preceded the formerly accredited Sousa in noting it. It is evidently a native of Brazil whence it was carried to Central America. Peanuts are native to America as shown by Sousa and the fact that all wild species of *Arachis* are American. Gabriel de Sousa distinguished 2 closely allied plants, the pacoba of America and the banana of Asia. The records of Garcia da Horta and the Tupi Indian traditions also indicate the existence of a pacoba or native American banana. Later crossing of the 2 in both the New and Old World obliterated the traces of the original kinds. The pineapple was originally restricted to Brazil (Gandavo, Costa) and spread thence to other parts of America and to the Old World, where it was well established in the 2nd half of the 16th century (Orta, Costa). The sour orange (*Citrus bigarada*) has been known in Portugal since the Moorish occupation. The sweet orange (*C. aurantium*) was brought to Portugal by Vasco de Gama, and early established in Brazil (Nobrega, Navarro). The Chinese orange (*C. aurantium sinensis*) was brought to Portugal in 1635 by Mascarenhas, and rapidly supplanted all others throughout the world. By 1518 sugar cane was already well established in Brazil (Herrera). Since Indian corn was already well known to the Portuguese when they discovered Brazil, little attention was given it by Cabral and his companions. Though the Spanish discovered corn and brought it to Europe they were much slower to develop it than the Portuguese. These facts account for Europeans, other than the Portuguese, giving greater attention to corn in their records of discovery. The work of Campos Novaes on the transition from *Euchlaena viridis* to corn and the early familiarity of the Portuguese with corn, break down the main arguments for its Old World origin. The writings of Gabriel de Sousa indicate that the bean (*Phaseolus vulgaris*) is a native of the New World. It was introduced into the Old World early in the 16th century and soon supplanted all other types of beans.—*L. B. Smith.*

11028. **GUILLAUMIN, A. Les fleurs de jardins. Tome II. Les fleurs d'été.** 175p. 64 col. pl. Paul Lechevalier: Paris, 1929. Pr. 36 fr.

11029. **HART, J. N. [Edited by]. Rose growing.** 128p. Illus. Ward, Lock & Co. Ltd.: London, 1929.—A manual of rose culture, primarily for English growers. The viewpoint is mainly that of the amateur. Varieties and classes of roses are discussed for English conditions. The book contains instructions for propagation by budding, cuttings, layering, grafting and division. The construction of rose hedges is treated. Pruning directions for different types of roses are given separately.—*C. G. Bowers.*

11030. **HOLMES, EBER. Rose garden primer.** 20Sp. 62 fig. A. T. DeLa Mare Co., Inc.: New York, 1930. Pr. $1.75.—This is a practical guide to the culture of outdoor roses, including origin, history and classification together with planting, pruning, winter protection, propagation, diseases, insects. There is a brief chapter on growing roses under glass. The author presents a classification of roses, with examples of the varieties in each class.—*C. E. Wildon.*

11031. **HUKILL, W. V., and R. C. WRIGHT. Preventing the freezing of cut flowers in transit.** *Florists' Exchange* 74(15): 9, 11. 1930.—Various methods of thermal insulation were tried. Packages containing water, in the form of wet wrappings of newspaper or wet cotton pads surrounding the flowers, cooled much more slowly than others and the temp. remained at 32° F. for a relatively long time before dropping. 32° is well above the freezing point for most flowers. The wet wrappings must be between the flowers and each surface of the box, so that heat transfer will take place through the water in the wrappings. A paraffined box is desirable.—*C. G. Bowers.*

11032. **JACOBS, HOMER L. Fertilization of shade trees. Part 2. Chemical fertilizers for conifers?** *Davey Inst. Tree Surgery Res. Dept. Bull.* 5 (1-15). 1930.—500 Norway Spruce trees were divided into 2 groups for treatment. The carriers used ranged from urea and ammonium sulphate to purely organic, mild and slowly available materials such as bone meal and cottonseed. Results at the end of 2 yr. gave no indication of harmful effects from the use of fertilizers. On the other hand they indicated a consistent improvement both in growth and color of the fertilized over the unfertilized trees.—*From author's summary.*

11033. **JONES, HENRY ALBERT, and SAMUEL LEONARD EMSWILLER. The vegetable industry.** 431p. 154 fig. McGraw-Hill Book Co., Inc.: New York, 1931. Pr. $2.25.—This book is planned primarily for high school students. The first 8 chapters (45 pages) deal

with problems confronting the vegetable grower: soils, planting, insects and diseases and control measures, exhibiting and judging. One chapter is devoted to culture of vegetable plants under glass. Vegetables are classified botanically according to families. Chapters X-XLIX deal with the culture of the important vegetable crops. 12 families are represented by 49 crops. The work concludes with a chapter on fields of work in truck crops other than production. Here the authors include a brief discussion of vegetable breeding, disease control, insect control, teaching, marketing, and inspection service.—*G. W. Woodbury.*

11034. KOBEL, FRITZ. Lehrbuch des Obstbaus auf physiologischer Grundlage. 274p. 63 fig. Julius Springer: Berlin, 1931. Pr. 16 M.—This work is intended to explain the physiological processes of most immediate importance in fruit production. These are, the author states, blossom bud formation and fruit development; accordingly the greatest space is given these processes. Following 33 pages of general physiology of fruit trees, 31p. are devoted to blossom formation, including normal development and the influence of various practices. Fruit development, comprising unfolding of blossoms, pollination, fertilization, sterility, parthenocarpy, June drop and ripening, is discussed in 129p.; of these, 22 are given to cytologically determined sterility. The 4th section (20p.) is devoted to a discussion of the relationship between vegetative growth, blossom formation and fruit formation. The author here presents his own classification of conditions (vigor and fruitfulness) into which trees may fall, and suggests treatments according to these conditions. The classes are recognized as grading into one another. Effects of root stocks are discussed at this point. The 5th section (24p.) treats of the raising of new varieties. The final 13p. contain literature citations, grouped alphabetically by sections. Of the citations for section 1, 41 are to papers by authors writing in English, 19 to papers in German and 3 to papers in French. Nearly all the illustrations are original.—*F. C. Bradford.*

11035. KORTLEVE, IR. A. Bemestingsproeven in de theecultuur. [English translation p. 120-135.] *Arch. Theecultuur Nederl. Indië* 2: 88-135. 1930.—Fertilizers applied to tea bushes resulted in an increased yield of 10-20%. Fertilizer was applied at the base of the plant. Ammonium sulphate, superphosphate and potassium sulphate were used on the basis of 30 lb. N, P and K per acre. The greatest increase of yield was from the addition of N.—*C. Yampolsky.*

11036. LAURIE, ALEX. Fertilizing ornamentals. *Minnesota Horticulturist* 59(1): 3-5. Portrait. 1931.—For nurseries, the substitution of peats for manures is recommended, since experimental work has shown that nutrients in peats can be made readily available through the addition of very small amounts of manure which contains cellulose-decomposing bacteria. Complete commercial fertilizers analyzing 4-12-4 are recommended for general purposes, but for trees, shrubs and evergreens 10-6-4 is more suitable. 2 applications should be made during the season—one in the spring and one in midsummer. Fall applications are not advised unless the soil contains much humus to retain the minerals until they may be of use in the spring.—*A. Laurie.*

11037. RUSCHMANN, W. Banane. In: **WOHLTMANN-BÜCHER'S** *Monographien zur Landwirtschaft warmer Länder.* Vol. 8. 146p. 35 fig. Deutscher Auslandverlag: Berlin-Charlottenburg, 1929.—In this handbook on banana cultivation the treatment of structural characteristics, reproduction, and taxonomy is brief: the discussion of chemical constitution of the fruit is even more limited. The chapter on cultivation contains sections on climate, soil, planting-material, planting-distances, methods of transplanting, manuring, catch-crops, etc. Harvesting and transport of the fruit are discussed, with a brief treatment of sea-transport. Diseases and pests are given a chapter of 16 pages. Other chapters deal with: profits, value of the banana as food for man, and for domestic animals; production of fiber; banana-products; statistics of production. A bibliography of the most important works on the banana is presented.—*C. D. LaRue.*

11038. SAYRE, C. B., J. J. WILLAMAN, and Z. I. KERTESZ. Factors affecting the quality of commercial canning peas. *New York State [Geneva] Agric. Exp. Sta. Tech. Bull.* 176. 1-76. 8 fig. 1931.—Tenderness was the principal quality factor investigated. The effect of potash fertilizers on peas was studied. Great differences in the mineral content of peas and ratios of minerals were obtained, but the organic constituents varied but slightly. Large differences in the inorganic content of the leaves and stems may be produced, but very little in the seeds and particularly the seed coats. All lots were canned under commercial conditions, and the quality of the canned product judged by experts. 3 deleterious changes occur if peas are not canned within a few hours after shelling: increased toughness, increased calcium in the seed coat, and enzymic changes in the CH and N constituents. Differences in the proportion of Ca and K in the nutrient solution can cause an organic base exchange in which Ca is partially replaced by K, and vice versa. The K and Ca content of peas was altered slightly by the application of the respective compounds to the soil. Potash fertilizers tend to reduce toughness of peas, and KCl is not injurious. However, $CaCl_2$ applied to the soil made peas tougher. Changes in peas (ovules) as they mature include increases in dry matter, starch, and protein-non-protein nitrogen ratio, and the migration of Ca to the seed coat, all of which tend to make the peas tougher. These changes can be measured by mechanical tests and indices of maturity which indicate canning quality. The use of a mechanical "quality index" is proposed to determine when fields should be harvested to obtain maximum yield and quality.—*C. B. Sayre, J. J. Willaman and Z. I. Kertesz.*

11039. THOMPSON, H. C. Vegetable crops. 2nd Ed. 560p. 60 fig. McGraw-Hill Book Co. Inc.: New York, 1931. Pr. $5.—This is designed as a textbook for college and university students. The author presents interpretations of previously published results of technical studies on the growth and physiology of vegetable crop plants, soil management, cultural methods, nutrition, and insect and disease control, emphasizing scientific evidence and basic principles upon which practical recommendations are made. A limited amount of experimental data is presented but most of the approximately 500 citations to literature involve only a brief summary and interpretation as related to the specific point under consideration. In the first 15 chapters are discussed: vegetables as food, vegetable classification, phases of the industry; the basic principles underlying the fertilizing, manuring, improvement and preparation of soils; crop rotation; growing of seeds, growing of plants for transplanting; planting, cultivation, mulching, irrigation, insect and disease control; marketing and storage. In the latter 12 chapters 68 vegetable crops are arbitrarily grouped for convenience of study and discussion, a chapter being devoted to each group, as: Perennial crops, pot herbs or greens, salad crops, root crops. Each crop is discussed with reference to its botanical characteristics, propagation, varieties, economic importance, history, climatic requirements, soil preferences and soil preparation, the use of manures and fertilizer, methods of planting, cultivation and care, harvesting, storing, preparation for market. The important diseases and insect pests attacking the crop are briefly described and the accepted control measures. The 2nd edition is amplified appreciably over the 1st edition (1923).—*V. R. Boswell.*

11040. WISTER, JOHN C. Bulbs for American gardens. xxv + 278p. 53 pl. 17 fig. The Stratford Co.: Boston, 1930.—The introduction, giving definitions, examples of uses, and sources of supply, is followed by 18 chapters on culture, types of bulb gardening, the better-known bulbs for the spring garden, bulbs for the rock garden (3 chapters), bulbs in the wild garden, hyacinths, daffodils (history), daffodils (species, varieties, classification),

daffodil culture, tulips (history and cultivation), tulips (garden varieties), late blooming bulbs, lilies, gladiolus, half hardy summer flowering bulbs, and tender bulbs. Appendix A is a list of named varieties of tulips, and Appendix B is a list of named varieties of daffodils.—*C. S. Gager.*

11041. **ALMEIDA, HUMBERTO de.** O mais velho exemplar vivo dos eucalyptos plantados no Brasil. [The oldest living eucalypt in Brazil.] *Revista Florestal* 1(11): 7-8. 1 fig. 1930.—A *Eucalyptus globulus* planted near Rio de Janeiro in 1867 is believed to be the oldest living specimen of *Eucalyptus* in Brazil.—*W. N. Sparhawk.*

11042. **ASSIS IGLESIAS, FRANCISCO de.** O crescimento das essencias florestaes brasileiras. [Growth of Brazilian forest trees.] *Revista Florestal* 2(1): 5-10. 6 fig. 1930.—Height and diameter growth of several Brazilian trees, mostly in botanical gardens.—*W. N. Sparhawk.*

11043. **DISSEL, E. D. van.** L'état et la sylviculture en Hollande. 18p. 2 pl. Administration Forestière de l'État Néerlandais à Utrecht (Staatsboschbeheer), 1931. —The wooded area of Holland has increased from 169,000 ha. in 1833 to 254,138 ha. in 1930, while the area of idle land has decreased from 889,000 ha. to 378,225 ha. The forest has gradually shifted from the better soils, which have been cleared, to those unsuited for cultivation. At the same time, broad-leaved trees (81% of area in 1833) have been replaced by conifers (60% in 1930), chiefly *Pinus silvestris.* Methods of afforestation are described.—*W. N. Sparhawk.*

11044. **DUBOSC, A.** Études sur les produits de la distillation des bois algériens. *Bull. Sta. Rech. Forest. Nord de l'Afrique* 1(7): 257-274. 1926.—The sources, chemical composition, methods of production, prices and probable value of the products from the distillation of gum, "light wood" (including waste and stump wood), and from pine needles, of various tree species in the U. S. A. and North Africa, are outlined. *Cedrus libani* var. *atlantica* is considered the most abundant and promising source of such products in N. Africa.—*J. Kittredge, Jr.*

11045. **DUFAY, M.** Le verglas de mars 1931. *Bull. Trimest. Soc. Forest. de Franche-Comté* 19(2): 88. 4 pl. 1931.—The terrible ice storm caused irreparable damage to coniferous plantations in the valley and plateau of the Doubs and in a part of Haute-Saône. The damage to *Pinus sylvestris* was greater in the 1898 plantations than in the older and younger ones. The Haguenau variety suffered much, the Scotch variety still more, and the stands of the Riga variety were almost destroyed. *P. austriaca* was up-rooted but not broken. *P. strobus* was damaged hardly at all. *Pseudotsuga taxifolia* suffered no damage.—*J. Kittredge, Jr.*

11046. **ESCHENLOHR, H.** Verjüngung heidekranker Föhrenbestände auf oberem Keupersand. *Forstwiss. Centralbl.* 53(16): 573-588; (17): 593-609. 1 fig. 1931.—A special technique is necessary in planting pine on dry, sterile, sandy soil which is poor in lime, colloids, and plant foods, and which is generally covered with heather. Best success is obtained by planting on clear-cut strips 30-40 m. wide, working from the northwest side of the stand. The heather should be cut and removed along with any excessive accumulation of raw humus and ground $CaCO_3$ should be applied at the rate of 5-8 tons per ha. The soil should then be plowed, birch seed sown in the fall, and 1 or 2-yr. pine and 2-yr. larch planted in the following spring. Perennial lupine should then be sown or alder seedlings planted between the rows, to enrich the soil.—*W. N. Sparhawk.*

11047. **FORS, ALBERTO J.** Cultivo de los Eucaliptos en Cuba. *Rev. Agric. Comerc. y Trab.* 11(10): [misprint for 12(4): ?] 39-42. 3 fig. 1931.

11048. **FORS, ALBERTO J.** Sobre la propagación, siembra y utilidades de los arboles del género Eucaliptus. [Propagation, sowing, and uses of eucalyptus trees.] *Rev. Agric. Com. y Trab.* [*Cuba*] 13(2): 34-37. 1931.—Soil preference and uses are given for 22 spp.

11049. **GEIGER, RUDOLF, und HANS AMANN.** Forstmeteorologische Messungen in einem Eichenbestand I. *Forstwiss. Centralbl.* 53(7): 237-250. 6 fig. 1931.—This paper describes the construction of towers 27 and 28 m. high, and the instrumental equipment for meteorological measurements below, in, and above the crowns of oak stands, one of which had beech understory and the other none.—*W. N. Sparhawk.*

11050. **GRISR, D. H.** Caoutchoutiers. [Rubber trees.] *Ann. Gembloux* 37(8): 232-237. 1931.—A review of the history and methods of rubber culture in the Malay States with notes on the methods of treatment of the latex and cost of production.

11051. **HACKMANN, GEORG.** Die forstlich wichtigsten Klimazahlen von Deutschland. [German climatic data most important for forestry.] *Mitteil. aus Forstwirtsch. u. Forstwiss.* 2(3): 503-519. 8 maps. 1931.

11052. **HARTMANN, F. K.** Grundlagen für eine natürliche Waldeinteilung und Waldbehandlung in Mitteleuropa. *Mitteil. aus Forstwirtsch. u. Forstwiss.* 2(3): 529-536. 1931.—Forest classification and management should be based on the natural factors that govern forest distribution and growth, viz.: climatic factors, determined by numerous measurements over a considerable period; and kinds and stage of development of soil, for which comprehensive maps are needed. Natural forest associations, changed little or not at all by human intervention, should be correlated with climate and soil.—*W. N. Sparhawk.*

11053. **HESSELMAN, HENRIK.** Tyska undersökningar över markvegetationens användning för skogsmarkens bonitering. [German investigations of the use of ground vegetation for estimating site qualities of forest soils.] *Skogsvårdsför. Tidskr.* 29(2): 164-169. 1931. —Attempts to apply Cajander's vegetation types in Germany have led to the conclusion that vegetation of the forest floor offers valuable indications for silvicultural treatment, but forms a poor basis for site classification.—*H. I. Baldwin.*

11054. **KUHLMANN, J. G.** Arvores que, na flora do Districto Federal, florescem nos mezes de Abril e Junho. [Trees of the Federal District (Brazil) which bloom from April to June.] *Revista Florestal* 2(1): 47-48. 1 fig. 1930.

11055. **KUHLMANN, J. GERALDO.** Uma Rhamnacea de cerne magnifico. [A species of the Rhamnaceae with excellent heartwood.] *Revista Florestal* 2(1): 54-55. 1 fig. 1930.—*Rhamnidium glabrum,* a small Brazilian tree, has fine-grained light yellow heartwood, which turns bronze-colored on exposure to air, polishes well, and is suitable for cabinet work.—*W. N. Sparhawk.*

11056. **POLANSKÝ, BOH.** Příspěvky ke studiu ekologické a fysiologické povaky lesních dřevin. (I.) Nároky sosnových a smrkových semenáčků na vlâhu. [Ecology and physiology of forest trees. (I.) Moisture requirements of pine and spruce seedlings.] [In Czech and German.] *Vestník Československ. Akad. Zem.* 7(1): 38-44. 5 fig. 1931.—Seedlings of *Pinus sylvestris* require more moisture than those of *Picea excelsa.* It is impossible to state whether this fact is due to differences in internal nutritional requirements or to differences in root systems. Probably it is because superficial moisture

cannot be used by pine to the extent that it can by spruce, which occasionally has the capacity to draw necessary moisture from the atmosphere. Thrifty spruce has an inherent tendency to put out numerous secondary branches in early life. Many failures in natural and artificial seeding of pine can be avoided, if it is recognized that this tree needs considerable actual precipitation and is not at all adapted to make use of atmospheric humidity and meager condensations therefrom.—*G. S. Perry.*

11057. **SARACHO, FRANCISCO.** Algunos datos sobre el vivero local de Monterrey, Estado de Nuevo León. [The Monterrey nursery, State of Nuevo León.] *Mexico Forest.* 9(7/8): 147-150. 1931.—Notes on the germination and 1st yr's. growth of various species of forest trees.—*W. N. Sparhawk.*

11058. **SCHWAPPACH, A.** Die Akazie in Nordostdeutschland. *Deutsche Forstzeitg.* 46(37): 883-884. 1931.—*Robinia pseudoacacia* was extensively planted in northeastern Germany in the last part of the 18th Century. The climate is too severe for it to do well, and further planting is not recommended.—*W. N. Sparhawk.*

11059. **SKUCE, THOMAS W.** Some problems of natural and artificial reforestation arising from West Virginia's cut-over timber land. *West Virginia Univ. Proc. West Virginia Acad. Sci.* 3: 48-62. 1929.—General statistics of the present and past forestry situation in West Virginia are cited, together with an outline of a program for future forestry activity and research in the state.—*W. R. Adams, Jr.*

11060. **STREHLKE.** Die russische Forstwirtschaft. *Deutsche Forstzeitg.* 46(34): 817-821; (35): 839-841. 6 fig. 1931.—The organization of forest administration and exploitation in Russia is described, with especial reference to the Ural region. Virgin spruce and fir stands, 150-200 yrs. old, seldom yield more than 220 cu. m. per ha., and 250-350-yr.-old pine forests ordinarily yield less than 250 cu. m. Silvicultural measures consist of little more than selecting the stands to be cut and in some instances of designating seed-trees. All merchantable timber is cut, and much material is wasted. Timber is transported to the rivers over iced roads by teams or tractors. Efforts are being made to build up a large technical personnel, and research is being pushed forward on a broad scale. An institution is being built near Moscow in which 2,000 research workers are to be employed after 1932.—*W. N. Sparhawk.*

11061. **WELCH, M. B.** Some mechanical properties of Australian grown Pinus insignis (P. radiata). II. *Jour. & Proc. Roy. Soc. N. S. Wales* 63: 111-121. 1929 (1930).—The comparative strengths of *P. insignis* grown in New S. Wales, Victoria and S. Australia were tested in conformity with the standard practice for testing small clear specimens adopted by the Forest Products Laboratory at Princes Risborough and elsewhere. The wood is by no means weak and brittle, and although considerable variation in the mechanical and physical properties occurs, there is no reason why much of the imported softwood should not be replaced by *P. insignis.*—*M. B. Welch.*

11062. **WELCH, M. B.** Some properties of Red Satinay, Syncarpia hillii. *Jour. & Proc. Roy. Soc. N. S. Wales* 63: 122-130. 2 pl. 1929 (1930).—Red Satinay (Myrtaceae) is a reddish colored, close textured wood, without natural figure, but often with a high degree of accidental figure. It is practically confined to Fraser Island, off the Queensland coast. The wood is inclined to be brittle and to fail suddenly without warning. Static bending and impact tests indicate a comparatively low energy absorption. The wood is remarkably fire resistant and is also very durable against both insect and fungal attacks.—*M. B. Welch.*

11063. **WIEDEMANN, E.** Starke Durchforstung und Schnellwuchsbetrieb. [Heavy thinning and management for rapid growth.] *Zeitschr. Forst- u. Jagdw.* 62 (11): 795-797. 1930.—A reply to Gehrhardt and Swart in the controversy involving the effect of this particular type of management upon growth.—*J. Roeser, Jr.*

11064. **WIEDEMANN, E.** Die Brauchbarkeit des verglichenen Durchmessers als Weiser für die Standortsgüte. *Zeitschr. Forst- u. Jagdw.* 62(11): 797-805. 1 fig. 1930.—A reply to Reinhold's theory of comparable diameter as the only useful indicator of the influence of site and of stand treatment on similarly-aged stands subjected to various methods of treatment. The increment on the Bavarian and Prussian experimental thinning plots showed no appreciable difference between moderate- and heavy-understory thinning for spruce, pine or beech. The mechanical concept of comparable or relative diameters, which disregards natural factors, cannot be accepted as a criterion for measuring variations in quality of site.—*J. Roeser, Jr.*

11065. **WITTICH.** Ueber die Ergebnisse einiger neuerer bodenkundlicher Untersuchungen in ihrer Bedeutung für die ostdeutsche Kiefernwirtschaft. *Deutsche Forstzeitg.* 46(32): 773-777; (33): 795-800. 1931.—The correlation between growth of forests and soil conditions is closer than has been realized. The deeper layers, down to 4-5 m., may have more influence than the surface layers, through their relation to water supply. Volume yield can not be influenced by silvicultural measures to the extent that many have believed, but quality and value yields can be. Reproduction of pine under shade is possible only on certain sites, especially where there is abundant soil moisture and little root competition.—*W. N. Sparhawk.*

11066. **ANONYMOUS.** O problema do reflorestamento. Quaes são as melhores madeiras do nosso paiz? [Reforestation. What are our best woods?] *Revista Florestal* 1(12): 9-11. 1930.—The following are recommended for planting in São Paulo, Brazil: (a) Fast-growing softwoods suitable for interior construction, boxes, etc., include *Araucaria brasiliana, Schizolobium excelsum, Cedrela* spp., *Enterolobium timboúva,* and *Chorisia speciosa;* (b) slower-growing trees with harder wood, suitable for exposed construction, railway ties, etc., include *Esenbeckia leiocarpa, Aspidospermum polyneuron, Caesalpinia peltophoroides, Machaerium* spp., *Dalbergia* spp., *Myrocarpus frondosus,* and *Toluifera peruifera;* (c) cabinet woods include *Phoebe porosa, Centrolobium robustum, Ocotea* spp., *Nectandra* spp., *Balfourodendron riedelianum* and *Jacarandá brasiliana.* —*W. N. Sparhawk.*

FUNGI

FUNGI

11067. **BOSE, S. R.** Polyporaceae of Bengal. VIII and IX. *Jour. Dept. Sci., Calcutta University* 9: 27-44. 19 pl. 1928.—Detailed descriptions are given of 24 spp., with plates showing the upper surface and the hymenial surface of almost all of them. Geographic distribution is recorded.—*S. R. Bose.*

11068. **CAYLEY, D. M.** Sex in fungi. *Nature [London]* 125(3153): 527. 1930.—A distinction is drawn between true sex heterothallism (haplo-synoecism) and

physiological heterothallism. The heterothallic Hymenomycetes are considered to be potentially bi-sexual, the so-called multi-polar behavior of certain spp. being attributed to the operation of negative sterility factors, as suggested by Brunswick. In *Humaria granulata* the mono-ascospore mycelia are to all appearances ♀, but when mated together fall into 2 definite groups in a 1:1 ratio. This is regarded as a form of physiological heterothallism determined by 1 self sterility factor.—*W. F. Hanna.*

11069. **HENLEY, A. T.** Involution cultures of yeast. 2. *Jour. Inst. Brewing* 37(4): 239-240. 2 fig. 1931.—A cultural study of *Saccharomyces intermedius* with special reference to concentration of wort-gel.

11070. **HIRATSUKA, NAOHIDE.** On some Japanese species of the Melampsoraceae. I. *Tottori Nagaku-Kwaiho (Trans. Tottori Soc. Agric. Sci.)* 2(1): 61-63. 1930.—This article treats of the synonymy and distribution of *Melampsora laricis* Hartig, *Hyalopsora aspidiotus* (Peck) P. Magn. and *Thekopsora sparsa* (Wint.) P. Magn. *H. aspidiotus* is previously unrecorded in Japan. The teleuto-stage of *T. sparsa* is reported for the first time in Japan.

11071. **KUSANO, SHUNSUKE.** The life-history and physiology of Synchytrium fulgens Schroet., with special reference to its sexuality. *Japanese Jour. Bot.* 5(1): 35-132. 19 fig. 1930.—A very detailed study was made of *S. fulgens,* which was found to belong to the section (Tobler's subgenus *Pleiochytrium*) in which the life cycle includes both a resting spore and a sorus of sporangia, and these phases were shown to correspond to the sexual and asexual phases respectively. A parallel development having previously been shown by Curtis in *S. endobioticum,* the author postulates as a general rule in this section of the genus that the resting cell is a sexual product and that the zoospore (gamete) is also capable of parthenogenetic development, giving rise to the summer sporangial phase.—*S. fulgens* is parasitic on *Oenothera lamarckiana* and *O. biennis,* invading the epidermal cells of leaves and stems, producing (1) an orange-colored sorus, about 100 μ in diam., containing typically about 50 gametangia; or (2) a resting cell, usually but 1 in each host cell, about 50-60 μ in diam. Either type of body ultimately gives rise to pear-shaped gametes, about 5 μ long, each provided with a single orange oil drop, and a long posterior cilium. All gametes are morphologically similar. When 2 gametes copulate and fuse a zygote is formed, which, after penetrating a host cell, develops into a resting spore; in the absence of copulation a single gamete may penetrate a host cell, whereupon it enlarges to fill the entire cavity of the host cell (which also enlarges), then the whole body undergoes endogenous segmentation, producing the gametangial sorus. On maturation of the sorus the wall of the host cell is broken and the gametangia become free, being moist and coherent at first, later dry and pulverulent; later they are dispersed. The resting cell germinates by the extrusion of a spherical sac, which is transformed into a gametangial sorus (exogenous) of the same size as the resting cell. Gametes derived from either type of gametangium sorus—the resting or winter stage, or the summer stage—may pair and produce zygotes, or undergo parthenogenetic development, giving rise to either a resting cell or a summer sorus respectively. At the time of copulation one of the gametes is typically sedentary, having lost its cilium and rounded up; the other gamete remains ciliated and pear shaped. Fusion is complete, including the nuclei, but the oil drops remain distinct, whereby a zygote can be distinguished from an encysted gamete. Copulation may take place between gametes derived from the same summer gametangium; thus the fungus is monoecious. Any external or internal condition favorable for the germination of the gametangium and for the activity of the gamete favors zygote formation, and vice versa. The gametes derived from a single gametangium differ in the inherent length of the swarm period, some coming quickly to rest, others remaining active for 1-2 hr. Likewise some gametangia produce gametes most of which come to rest after a short swarm period, and other gametangia produce typically long-swarming gametes. Each gamete behaves as a ♂ during the early and active period, and as a ♀ during the later and sedentary period. As the fundamental condition for copulation is that 1 gamete is sedentary, the other active, the contemporaneous germination of several gametangia affords increased opportunities for zygote formation. Temp. is the principal external factor in zygote formation, 20° C. being about the optimum. Lower temp. causes uneven germination of the gametangia, and supraoptimal temp. causes sluggish motion of the gametes.—Among the zygotes and azygotes entering the same host cell, competition for development occurs. When the host cell is low in vitality the zygotes survive, otherwise the azygotes succeed in developing into summer sori.—Gametangia from both summer and winter sori remain viable for 3 months if the temp. is low (4-5° C.) and if protected from desiccation. The resting cells stored air dry remain viable for 7 yr., and those kept in water remain dormant for half this time. They can however be brought to germination without overwintering or exposure to drought within 3-4 weeks of their formation, but germination of resting cells which remain inclosed within the host cells is greatly delayed.—*F. Weiss.*

11072. **LAGERBERG, T., G. LUNDBERG, and E. MELIN.** Biological and practical researches into blueing in pine and spruce. *Svenska Skogsvårdsföreн. Tidskr.* 25(2): 145-272; (4): 561-739. 2 col. pl. 93 fig. 1927.—Sixteen spp. and forms of Swedish fungi were isolated and investigated; 5 of them belong to Ceratostomataceae, 3 to Sphaeropsidaceae and 8 to Hyphomycetes. *Penicillium biforme* Thom, isolated from wood, causes a distinct blueing. Sphaeropsidaceae: *Sclerophoma* **entoxylina*** (p. 209); *Discula* **pinicola** (*Ligniella p.* Naumov) Petrak (p. 211). Hyphomycetes: **HORMONEMA** (p. 233), type *H.* **dematioides*** (p. 233); *Trichosporium* **tingens*** (p. 238); *Hormodendrum* **microsporum*** (p. 247); **LEPTOGRAPHIUM** (p. 257), type *L.* **lundbergii*** (p. 257); **CADOPHORA** (p. 263), type *C.* **fastigiata*** (p. 263). The influence of environmental factors (water and O content, temp., specific quality of the wood) on the growth of the fungi in the wood was investigated, and practical tests were made to find the most suitable methods of storing timber so as to prevent the occurrence of blueing.—*T. Lagerberg.*

11073. **MOESZ, G. v.** Neue Pilze aus Lettland. *Magyar Bot. Lapok* 29: 35-38. 1930.—The following are described by Moesz and Smarods: *Diplodina* **lini** (p. 35) on *Linum usitatissimum; Hendersonia* **sorbi** (p. 35) on *Sorbus aucuparia; Pleurophoma* **latvica*** (p. 36) on *Galium; Ramularia* **coriandri*** (p. 37) on *Coriandrum sativum; Stagonospora* **ophioboli*** (p. 38) in perithecia of *Ophiobolus* on *Galium. Septoria* **smarodsii*** (p. 37) on *Amaranthus adscendens.*—*C. Schermann.*

11074. **PETRAK, F.** Mykologische Beiträge zur Flora von Spanien, Portugal und der Insel Madera. *Ann. Mycologici* 29(1/2): 107-128. 1931.—*Anthostomella* **maderensis** (p. 107), on dead leaves of *Aloe* sp., Madeira; *Cucurbitaria quercina* Ell. and Ev., on *Quercus lusitanica* v. *jaginea,* described; *Entodesmium* **nevadense** (p. 109), on decaying stems of *Carduus granatensis,* Spain; *Mycosphaerella* **hepaticae** (p. 110), on dead branches of *Hepatica hispanica,* Spain, and associated with it, *Asteromella pycnidia; M.* **lygei** (p. 111), on dead leaves of *Lygeum spartium,* Spain, apparently part of the Formenkreis of *M. tassiana; M.* **monserratica** (p. 113), on dead branches of *Aphyllanthes monspeliensis,* Spain; *M.* **stipina** (p. 113), on dead leaves of *Stipa juncea,* Spain; *Pleospora echiicola* Pet., 2 forms of perithecia described; *P. mauritanica* Maire, described; *P.* **nevadensis** (p. 116), on dead stems of *Ptilotrichum spinosum,* Spain; *P. paronychiae* Cke., described; *P. permunda* (Cke.) Sacc., described from various hosts, with reference to its belonging to *Pleospora* or *Pyrenophora; Gloniella* **adianti** (*Hysterium a.* Kze), described; *Asco-*

chytella maderensis (p. 121), on dead branches of *Globularia salicina*, Madeira; *Asteromella* adeana (p. 122), on decaying leaves of *Viburnum tinus*, Spain; *Coniothyrium* jaenense (p. 123), on dead stems of *Rebania sphaerocarpa*, Spain; *C.* maderense (p. 124), on dead stems of *Teucrium betonicum*, Madeira; CYTODISCULA (p. 125) [apparently *Zythiaceae*], based on *C.* carnea (p. 125), on dry rotten wood of *Laurus canariensis*, Madeira; *Hendersonia opuntiae*, described; *Phoma* andryalina (p. 127), on dead stems of *Andryala ragusina*, Spain.

11075. PICBAUER, RICH. Additamentum ad floram Jugoslaviae mycologicam. *Glasnika Zemaljskog Muz. u Bosni i Hercegovini* 41(1): 29-34. 1 fig. 1929. Also: *Opera Inst. Phytopath. Brunae* (*Brno in Czechoslovakia*) No. 87. 29-34. 1 fig. 1929.—An annotated list of Myxomycetes; Phycomycetes; Ascomycetes; Basidiomycetes, including *Gymnosporangium* malýi* (p. 32) on *Crataegus monogyna*, type in Malý coll.; and Fungi Imperfecti.

11076. RAMSEY, G. B. Oospore stage of Peronospora viciae on peas. *U. S. Dept. Agric. Bur. Plant Indust. Plant Dis. Reptr.* 15(6): 52-53. 1931.—[Mimeographed.]

11077. SAWADA, KANEYOSHI. Descriptive catalogue of the Formosan fungi. Part V. [In Japanese.] *Dept. Agric. Govt. Res. Inst. Formosa, Rept.* 51. 1-131. 5 pl. 1931.—The following are published, apparently with descriptions in Japanese: *Phytophthora* cyperi-iriae* (p. 13) on *Cyperus iria*; *Plasmopara* chrysanthemi-coronarii* (p. 15) on *Chrysanthemum coronarium*; *Meliola* acaciae-confusae* (p. 16) on *Acacia confusa*; *Zukaliopsis* gardeniae* (p. 23) on *Gardenia florida*; *Aleurina* nigrodisca* (p. 30); *Nectria* citricola* (p. 32) on *Citrus tankan* f. *koshotankan*; *N.* pterospermi* (p. 33) on *Pterospermum acerifolium*; *Melampsora* salicis-warburgi* (p. 47) on *Salix warburgi*; *Phakopsora* circumvallata* (p. 49) on *Artemisia*; *Triphragmium* formosanum* (p. 52) on *Koelreuteria bipinnata*; *Uredo* milletiae* (p. 55) on *Milletia reticulata*; *Septobasidium* parlatoriae* (p. 57) on *Parlatoria zizyphus*; *Exobasidium* pieridis-ovalifoliae* (p. 65) on *Pieris ovalifolia*; *Anellaria* ochroleuca* (p. 83); *A.* planiuscula* (p. 84); *Armillaria matsudake* var. formosana* (p. 90) on *Pinus taiwanensis*; *Phoma* lebbek* (p. 102) on *Albizzia lebbek*; *Hendersonia* citricarpa* (p. 104) on *Citrus unshu*; *Sphaceloma* batatas* (p. 105) on *Ipomoea batatas*; *Glocosporium* hibisci-tiliacei (p. 106) on *Hibiscus tiliaceus*; *Cylindrosporium* phalaenopsidis* (p. 108) on *Phalaenopsis aphrodite*; *Cladosporium* sclerotiophilum* (p. 112); *Helminthosporium* citri* (p. 113) on *Citrus* spp.; *Spondylocladium* tremae (p. 114) on *Trema orientalis*; *Thyrospora* solani (*Stemphylium s.* Weber) (p. 115); *Alternaria* americana "n. sp." (*A. solani* (Ell. & Mart.) (Jones & Grout) (p. 117); *Alternaria* macrospora (*A. brassicae* var. *m.* Sac.) (p. 123); *Cercospora* lagerstroemiae-subcostatae* (p. 129) on *Lagerstroemia subcostata*; *C.* panici-miliacei* (p. 131) on *Panicum miliaceum*.

11078. SIBILIA, CESARE. Un nuovo genere di Demaziacee didimospore. [A new didymosporic genus of the Dematiaceae.] *Boll. R. Staz. Patol. Veg.* 8(4): 445-448. 2 fig. 1928.—ARTHROBOTRYELLA, near *Arthrobotrys*, with *A.* hernica, from rotting wood, Italy.—*L. R. Tehon.*

11079. SOUZA da CAMARA, MANUEL de. Proposta de divisão do género Stemphylium Wallr., fungo da ordem das Hyphales (Mart.) em. Sacc. et Trav. [Proposed division of the genus Stemphylium Wallr.] [Text in Portuguese and French] 21p. 8 fig. Emprêsa do Anuario Comercial: Lisboa, 1930.—*Stemphylium* dendriticum* (p. 12) is found on the spots of the *Fusicladium* sp. which attack apple and Japanese medlar in Portugal. The author considers spore formation a character sufficiently important for generic distinction, and therefore proposes a division of the genus retaining the name *Stemphylium* for those spp. with acrogenous conidia and designating as SOREYMATOSPORIUM (p. 18) those in which the conidia are pleurogenous.—*M. de Souza da Camara.*

11080. UNAMUNO, LUIS M. Contribución al estudio de los hongos microscópicos de la provincia de Salamanca. *Bol. R. Soc. Espan. Hist. Nat.* 31(2): 85-96. 1931.—Annotated list of: Uredinales (26); Ustilaginales (4); Oomycetes (1); Pyrenomycetes (6); Discomycetes (2); Sphaeropsidales (17) including *Septoria bromi* var. septulata (p. 92) on *Bromus maximus*, *Stagonospora* caricicola (p. 93) on *Carex*, and *Camarosporium* armeriae (p. 93) on *Armeria littoralis*; Hyphomycetes (13).

11081. WAKEFIELD, E. M. Fungi exotici: XXVII. *Kew Bull. Misc. Inform.* 1931(4): 201-206. 4 fig. 1931.—The following are new: *Merulius* miniatus (p. 201), New Zealand, *Aleurodiscus* peziculoides (p. 201), New Zealand; *Uromyces* rhodesicus (p. 202) on *Bauhinia*, Tropical Africa; *Aecidium* hederae (p. 202) on *Hedera helix*, India; *A.* lophopetali (p. 203) on *Lophopetalum wightianum*, India; *Sphacelotheca* sclerachnes (p. 203) on *Sclerachne punctata*, Siam; *Septoria* cotyledonis (p. 203) on *Cotyledon orbiculata*, So. Africa; *Septogloeum* punctatum (p. 204) on *Eugenia cordata*, So. Africa; *Beltrania* (?) malaiensis (p. 205) on *Dichopsis gutta*, Malaya; *Cercospora* didymochitonis (p. 205) on *Didymochiton richii*, Fiji; *Pucciniopsis* caffra (p. 206) on *Erica caffra*, So. Africa; *Pucciniopsis* quercina (p. 206) on *Quercus dilatata*, India.—*A. D. Cotton.*

11082. YONEMOTO, SEIITI, and HUZIO KATO. Factors influencing the perithecial formation of Aspergillus glaucus Link. *Bull. Miyazaki Coll. Agric. & Forestry* 3. 59-94. 1931.—Perithecial formation is most vigorous at about 28°C.; it never occurs below 15°C. Light and ultraviolet rays have no effect. Presence of water influences development on solid media; on liquid media the perithecia also form abundantly. Dextrose, glucose, maltose, sucrose, levulose, glycerin and galactose promote formation of perithecia; inulin, glycogen, raffinose and corn starch have no noticeable effect. N compounds are less favorable than carbohydrates. The presence of 5% salt favors perithecial growth; presence of other fungi appears to check it.

11083. YAKUSHIJI, E., und M. KUMAZAWA. Eine auf Käfern parasitierende Pilzgattung Tilachlidiopsis aus Japan. [In Japanese.] *Bot. Mag. Tokyo* 44(524): 461-463. 4 fig. 1930.—The 3rd sp. of the genus, *T.* nigra (*Isaria n.* Yakus & Kumaz) (p. 461), occurs on adults or larvae of a beetle, *Carabus insulicola* Chaudoir, in Japan (Koishikawa Botanical Garden).—*M. Kumazawa.*

MYXOMYCETES

11084. MEYLAN, CH. Recherches sur les Myxomycètes en 1927-28. *Bull. Soc. Vaudoise Sci. Nat.* 57(223): 39-47. 1 fig. 1929.—Notes on 15 spp. from the Jura Mts. and Alps are given. The diameter of the spores from normal sporangia is believed to vary within narrow limits for a species and to serve as a very safe criterion for the separation of species. *Didymium* nivicolum (p. 40), Alps, and *Lamproderma* splendens (*L. sauteri* Rost. pro parte) (p. 44), Jura, are described as new spp. *Comatricha* brachypus (*C. nigra* var. *brachypus* Meyl.) (p. 41), Jura, and *Trichia* crenulata* (*T. contorta* var. *crenulata* Meyl.)—*F. L. Howard.*

LICHENES

11085. GALLØE, OLAF. Natural History of the Danish Lichens. Original investigations based upon new principles. Part II. 84p. 128 pl. H. Aschehoug & Co.: Copenhagen, 1929. Pr. 54 Kr.—Description and figures of individual specimens of the following genera as previously given for Part I (See Biol. Absts. 2, no. 18702, 1928), *Psora, Catillaria* (including *C.* chroolepus, and *C.* graminicola n. sp.), *Bilimbia* (including *Bilimbia* subsphaeroides* (*B. sabuletorum* var. *s.* Nyl.) (p. 53); *B.* melaenida* (*B. sabuletorum* f. *m.* Nyl.) (p. 56); *B.* ternaria* (*B. milliaria* f. *t.* Nyl.) (p. 59), and *Bacidia.*—*O. Paulsen.*

11086. GALLØE, OLAF. Natural history of the Danish lichens. Original investigations based upon new principles. Part III. 114p. 127 pl. H. Aschehoug & Co.: Copenhagen. 1930.—Description and figures of individual specimens of the following genera as previously given for Part I (see Biol. Absts. 2, no. 18702, 1928): *Lecanactis, Arthroraphis, Microphiale, Pachyphiale, Bryophagus, Biatorella, Mycoblastus, Blastenia, Catocarpon, Rhizocarpon* (including *R.* **danicum**), and *Diplotomma*.—*O. Paulsen.*

BRYOPHYTA

(See also in this issue Entries 9063, 11187)

11087. ALLORGE, PIERRE. Notes sur la flore bryologique de la Péninsule Ibérique. IV. Sur quelques Muscinées intéressantes de la vallée de Bidassoa. V. Le Riccinia perennis (Steph.) Trabut en Algarve. *Rev. Bryologique* 3(1/2): 80-87. 1 map. 1930.—IV contains notes on 5 Hepaticae and 8 Musci.—V records the occurrence of *Riccinia* (originally *Riccia*) *perennis* in Portugal, previously known only from Algeria and Italy. —*A. LeRoy Andrews.*

11088. ALLORGE, PIERRE. Notes sur la flore bryologique de la Péninsule Ibérique. VIII. Additions à la flore Portugaise. *Rev. Bryologique* 4(1): 32-36. 1931. —An annotated, critical list.

11089. BIZOT, MAURICE. Contribution à la flore bryologique de la Côte d'Or [France]. *Rev. Bryologique* 4(1): 17-31. 1931.—An extensive annotated list of mosses and hepatics, including *Neckera crispa* v. julacea (p. 26).

11090. CLARK, LOIS, and T. C. FRYE. Hepaticae new to some Northwestern States. *Bryologist* 34(4): 54-55. 1931.—24 spp. not before reported for the section are listed from Montana, Idaho, Washington, and Oregon. —*A. M. Taylor.*

11091. FLEISCHER, MAX. Bemerkungen über "Morphologische Untersuchungen über die Phylogenie der Laubmoose" von W. Stepputat und H. Ziegenspeck (Königsberg). *Ann. Bryologici* 3: 89-96. 1930.—A critique of the serodiagnostic method of establishing relationships in mosses versus the morphological.

11092. GARDET, G. Trois Muscinées intéressantes du "Roc-de-Chère," Lac d'Annecy (Haute-Savoie). *Rev. Bryologique* 4(1): 40-41. 1931.

11093. GROUT, A. J. Bryology by automobile. *Bryologist* 34(4): 51-53. 1931.—Of several spp. found in Florida and northward, the most interesting was *Fissidens incurvus* var. *exiguus* growing in the Grand Caverns of West Virginia in the glare of electric lights.—*A. M. Taylor.*

11094. HILLIER, LOUIS. Sur deux hépatiques peu répandues dans le Jura. *Rev. Bryologiques* 4(1): 38-40. 1931.—*Frullania fragilifolia* Tayl. and *Reboulia hemisphaerica* Raddi.

11095. MARQUAND, C. V. B. A new species of Exormotheca from South Africa. *Kew Bull. Misc. Inform.* 1930(6): 237-239. 3 fig. 1930.—*Exormotheca* **megastomata*** (p. 237), Transvaal. This liverwort is remarkable for its powers of drought resistance, doubtless assisted by the large hyaline stomata on the dorsal surface. *C. V. B. Marquand.*

11096. MINKEVIČIUS, ANT. Pradmenys Lietuvos samanų florai tirti. [Study on the Lithuanian moss flora.] [With German summary.] *Vytauto Didžiojo Univ. Mat.-Gamtos Fak. Darbai* 5(2): 290-325. 1930/1931.—An annotated list of 207 spp. and many forms, with localities and habitats, based on the author's collections (1925-1928) and on the rich collection in the Univ. of Lithuania.

11097. PITMAN, EVADEL M. Mosses of Orr's Island, Maine. *Bryologist* 34(4): 57-58. 1931.—Several mosses, 1 hepatic and 1 lichen are mentioned.—*A. M. Taylor.*

11098. POTIER de la VARDE, R., et I. THÉRIOT. Recherches sur les affinités du genre Acanthocladiella. *Rev. Bryologique* 3(1/2): 5-11. 1 pl. 1930.—*Acanthocladiella*, proposed by Fleischer in 1914 for a moss of Madagascar, to which several African spp. have since been added, is of uncertain affinity, as shown by the divergent views of bryologists. The present authors agree with Fleischer that the genus belongs in the subfamily Heterophylloideae of the family Sematophyllaceae and hold that its species should be included in the genus *Heterophyllium*. Three n. combs. result: *H.* **flexile*** (*Microthamnium f.* R. & C.), *H.* **kilimandscharicum*** (*Acanthocladiella kilimandscharica* Broth. & P. de la V.), *H.* **transvaaliense*** (*A. transvaaliensis* Thér. & Dix.). All are figured, together with several other closely related species of *Heterophyllium*.—*A. LeRoy Andrews.*

11099. REIMERS, H. Über Orthodicranum allorgei Amann et Loeske, Dicranum canariense Hpe. und D. scottianum Turn. *Notizbl. Bot. Gart. u. Mus. Berlin-Dahlem* 10(99): 943-945. 1930.—*O. allorgei* Amann & Loeske and *D. canariense* Hpe. are merely the ssp. *canariense* (Hpe.) Corb. (as var.) of *Dicranum scottianum* Turn. emend Reim. The members of this subspecies are restricted to Spain, Madeira, the Canaries, and the Azores. *Dicranum scottianum* ssp. **anglicum** (p. 944) is new; to it belong plants from Denmark, Norway, Great Britain, France, and Spain (?).—*A. M. Johnson.*

11100. REIMERS, H. Bericht über die auf dem Herbstausflug des Vereins in die Gamensee-Rinne am 19. Oktober 1930 beobachteten Moose. *Verhandl. Bot. Ver. Prov. Brandenburg* 73(1): 84-89. 1931.—The mosses observed are listed and discussed.

11101. SARRASSAT, CL. Quelques Muscinées nouvelles pour la Corse. *Rev. Bryologique* 4(1): 37-38. 1931.—A critical list.

11102. SVIHLA, RUTH DOWELL. Notes on Buxbaumia piperi in western Washington. *Bryologist* 34(4): 56. 1931.—Widely distributed throughout the region. —*A. M. Taylor.*

11103. VERDOORN, FR. Hepaticae selectae et criticae, series I. (1930). Series II. (1931). *Ann. Bryologici* 4: 122-139, 140-150. 12 fig. 1931.—The author, assisted by Ch. Douin and Th. Herzog, discusses the morphological characteristics, habitats and other ecological data for 24 liverworts (geographical ranges, synonyms and literature citations of special significance are given in many cases): *Cryptomitrium himalayense* and *Grimaldia dichotoma*, India; *Mittenia zollingeri*, Java; *Jamesoniella sonderi*, Tasmania; *Plagiochila confundens* v. **alpinoides** Herzog (p. 126), Panama; *Lophoziella integerrima, Evansia dentata, Prionolobus turneri, Cephaloziella striatula* and *C. gracillima* f. *rubra*, France; *C. rappii*, N. America; *C. hampeana* v. *elongata* and *C. curnowii*, France; *Lepidozia ulothrix*, Tasmania; *Madotheca chilensis*, Chile; *Jubula hutchinsiae* ssp. *javanica, Frullania campanulata* and *F. microauriculata*, Java; *F. nepalensis*, Celebes, Malay Penins.; *F. sinuata, F. claviloba, F. junghuhniana* and *Metzgeriopsis pusilla*, Java; *Bryopteris tenuicaulis*, Panama. II. The author, assisted by G. Chalaud, W. E. Nicholson and V. Schiffner, similarly treats the following: *Pallavicinia radiculosa*, Java; *Makinoa crispata*, Japan; *Treubia insignis*, Java; *Sewardiella tuberifera*, India; *Fossombronia cristula* v. **verdoornii*** Chal. and *Calobryum blumei*, Java; *C. rotundifolium*, Japan; *Marsupella vulcanica, Haplozia stricta* v. *radicellifera, Jamesoniella microphylla, J. ovifolia, Anastrophyllum piligerum, Chiloscyphus asselliformis* and *Zoopsis argentea*, Java; *Frullania moniliata*

ssp. *breviramea*, Sumatra, Java; *F. orientalis*, Java; *F. nigricaulis*, Sumatra, Jáva; *F. integristipula*, Java; *F. nodulosa*, Java, Borneo.—*A. J. Sharp.*

11104. **WILLIAMS, R. S. Blindia roerichii, sp. nov.** *Bryologist* 34(4): 49-51. 1 pl. 1931.—From the Himalayan mountains.—*A. M. Taylor.*

PTERIDOPHYTA

C. A. WEATHERBY, *Editor*

(See also in 6(3): Entries 6074, 6259, 8118, 8142, 8151, 8169; and in this issue 9063, 9130, 11144, 11148, 11206, 11209, 11222)

11105. **JACOT, ARTHUR PAUL. Asamushi hillside ferns.** *Lingnan Sci. Jour.* 10: 1-4. 1931.—13 spp. are recorded from northern Nippon. To account for the unequal geographical distribution though the spores are so easily transported, it is suggested that perhaps a symbiotic organism, probably of the soil, spreads much more slowly or precariously.—*A. P. Jacot.*

11106. **OGATA, MASASUKE. Icones filicum Japoniae.** [Text in Japanese, with scientific names in Latin.] 3 vols. 150 pl. Publ. Sansyusya: Tokyo, 1928-1930. Price 33 yen.—A selection of 150 Japanese ferns; 50, arranged alphabetically, per volume. Hymenophyllaceae (5), Polypodiaceae (145). Preface, introduction and descriptive text in Japanese; scientific names, synonymy and index in Roman type; explanation of plates in English. Each species has a page of description and a plate 10 × 15 in. illustrating the complete plant and about 15 enlarged details made from drawings by the author, assisted in some cases by NOBUKO OGATA. The material for illustration was collected in an area extending from Hokkaido to Formosa.—*A. N. Leeds.*

SPERMATOPHYTA

FRANCIS W. PENNELL, *Editor*

GENERAL

11107. **EMBERGER, L., et R. MAIRE. Matériaux pour la flore marocaine. Fascicule 1.** *Mém. Soc. Sci. Nat. Maroc* 21/22. p. 21-53. 1929.—This paper treats of about 140 new or little-known plants, from both French and Spanish Morocco, with descriptive, taxonomic, and distributional notes. *Myosurus minimus* v. **brevipes** (p. 22); *Fumaria reuteri*, new to Africa; *Hesperis laciniata* v. **rifana** (p. 23); *Brassica* **desnottesii** (p. 23); *B. saxatilis* ssp. *nudicaulis* v. **brevisiliqua** (p. 24); *B. fruticulosa* ssp. **dolichocarpa** (p. 24); *Erucastrum leucanthum* v. **luteum** (p. 24); *Rytidocarpus moricandioides* v. **stenocarpus** (p. 25); *Halimium umbellatum* v. **villosissimum** (p. 25); *Dianthus gaditanus* ssp. **atrosanguineus** (p. 26); *Silene heterodonta* v. **platycalyx** (p. 26); *S. mesatlantica* v. **macrotricha** (p. 27); *Arenaria grandiflora*, new to Morocco; *Spergularia pitardiana* v. **villosa** (p. 27); *Paronychia kapela* ssp. *serpyllifolia* v. **hirta** (p. 27); *P.* **pseudo-aretioides** (p. 27); *P. capitata* v. **longistyla** (p. 28); *Linum suffruticosum* ssp. *eu-suffruticosum* v. **matris-filiae** (p. 28); *L. austriacum* ssp. *gaetulum* subv. **albo-violaceum** (p. 29); *Lotononis* **bullonii** (p. 29); *Genista scorpius* ssp. **mesatlantica** (p. 30); *Cytisus catalaunicus* v. **intermedius** (p. 30); *Anthyllis vulneraria* ssp. **matris-filiae** (p. 30); *Astragalus ibrahimianus* v. **mesatlanticus** (p. 31); *Coronilla valentina* ssp. *glauca* v. **zaianica** (p. 32); *Hedysarum humile* vars. **speciosum, subspeciosum** and **mesanthum** (p. 32); *Vicia glauca* v. **mesatlantica** (p. 33); *V.* **delmasii** (p. 33); *Potentilla caulescens* v. *petrophila*, new to N. Africa; *Rosa micrantha* v. **perglandulosa** R. Keller (p. 34); *Alchemilla cornucopioides*, new to Africa; *Pirus mamorensis* v. **brevipes** (p. 34); *Oenanthe crocata* L. (=*O. apiifolia* Brot.); *Caucalis bifrons* v. **subtuberculata** (p. 35); *Fedia cornucopiae* v. **hirsuta** (p. 35); *Oldenlandia capensis* v. **inconstans** Maire (*O. i.* Pomel) (p. 36); *Scabiosa graminifolia* v. **condensata** (p. 36); *Anthemis punctata*, new to Morocco; *Leucanthemum* **mesatlanticum** (p. 38); *L. fontanesii, Artemisia absinthium* and *Senecio delphinifolius*, new to Morocco; *Echinops bovei* v. **glabrescens** (p. 38); *Centaurea* **eriosiphon** (p. 39); *C. lagascae*, new to Morocco; *C. boissieri* v. **transmalvana** (p. 39); *C.* **theryi** (p. 39); *Onopordon* **mesatlanticum** (p. 40); *Scorzonera graminifolia*, new to Africa; *Hieracium lawsonii* ssp. *flocciramum* v. **atlanticum** Maire & Zahn (p. 41); *H. phlomoides* ssp. **mesatlanticum** Maire & Zahn (p. 41); *H. pseudopilosella* ssp. *tenuicaule* forms **subeglandulosum** Zahn and **pilosicaule** Zahn (p. 42); *Erica terminalis*, new to Africa; *Armeria villosa* v. **zaianica** (p. 42); *Convolvulus* **mazicum** (p. 43); *Veronica rosea* v. **virgata** (p. 44); *Thymus serpyllum* ssp. *atlanticus* v. **leiodontus** (p. 45); *Sideritis* **matris-filiae** (p. 45); × *Marrubium* **humbertii** (*M. ayardii* × *multibracteatum*) (p. 46); *Teucrium musimonum* v. **matris-filiae** (p. 46), with f. **albo-roseum** (p. 47); *T. m.* var. **mesatlanticum** (p. 47); *T.* **zaianum** (p. 47); *Chenopodium crassifolium*, new to N. Africa; *Laurus nobilis* v. **rotundifolia** (p. 47); *Euphorbia* **mazicum** (p. 48); *Carex nitida*, new to Africa; *Juniperus communis* v. *hemisphaerica*, new to Morocco; *J. thurifera* v. *africana* f. **pyramidalis** (p. 52).

GYMNOSPERMAE

11108. **FITSCHEN, JOST. Die Gattung Tsuga.** *Mitteil. Deutsch. Dendrol. Ges.* 41: 1-11. 4 fig. 1929.—A description of 15 spp. of *Tsuga* with their varieties. The principal ones under cultivation are: *T. canadensis, T. heterophylla, T. diversifolia, T. sieboldii, T. caroliniana* and *T. pattoniana. T. canadensis* is often mistaken for *T. heterophylla* and *T. diversifolia* for *T. sieboldii.*—*J. C. Th. Uphof.*

11109. **HICKEL, R. Taxacées.** In: **H. LECOMTE. Flore Générale Indo-Chine** 5(10): 1062-1071. 1 fig. 1931.—*Taxus* (1 sp.), *Cephalotaxus* (2 spp.), *Podocarpus* (4 spp.) and *Dacrydium* (1 sp.) are described.—*E. D. Merrill.*

11110. **HICKEL, R. Araucariacées.** In: **H. LECOMTE. Flore Générale Indo-Chine** 5(10): 1071-1073. 1 fig. 1931.—A single representative, *Cunninghamia sinensis** R. Br.—*E. D. Merrill.*

11111. **HICKEL, R. Abiétacées.** In: **H. LECOMTE. Flore Générale Indo-Chine** 5(10): 1073-1079. 3 fig. 1931.—*Keteleeria davidiana* and 4 spp. of *Pinus* (with key) are recognized.—*E. D. Merrill.*

11112. **HICKEL, R. Cupressacées.** In: **H. LECOMTE. Flore Générale Indo-Chine** 5(10): 1079-1085. 2 fig. 1931.—*Cupressus*, with 2 spp., and *Fokienia, Biota, Libocedrus* and *Juniperus*, each with 1 sp., are recognized.—*E. D. Merrill.*

11113. **LEANDRI, J. Gnétacées.** In: **H. LECOMTE. Flore Générale Indo-Chine** 5(10): 1054-1062. 2 fig. 1931.—Six spp. of *Gnetum* (with keys) are recognized and described.—*E. D. Merrill.*

11114. **LEANDRI, J. Cycadacées.** In: **H. LECOMTE. Flore Générale Indo-Chine** 5(10): 1085-1092. 1931.—Eight spp. of *Cycas* are recognized with keys, including

C. pectinata var. **elongata** (p. 1091) and *C.* **chevalieri** (p. 1092).—*E. D. Merrill.*

11115. **PEARSON, H. H. W.** Gnetales. vi+194p. 3 pl., 1 portrait, 90 fig. Cambridge University Press: Cambridge, 1929.—When Pearson died in 1916, this book was nearly written but needed some revision. A. C. SEWARD of Cambridge and Mrs. THODAY completed the work, which was the result of Pearson's extensive studies in the field and in the laboratory. There are five chapters: I. Habit, distribution, ecology, taxonomy. II. Vegetative morphology and anatomy. III. The inflorescence and flower. IV. Reproduction. V. Theoretical. The book presents a full résumé and discussion of previous work and contains an extensive bibliography. The author's own contribution is strongest in the descriptions of field conditions, structure and development. The general conclusion states that the interrelationships of the three genera, *Ephedra, Gnetum* and *Welwitschia,* are as vague as before; but the evidence indicates that, in spite of the occurrence in them of some angiospermous characters, they are essentially gymnosperms.—*C. J. Chamberlain.*

11116. **PILÁT, A., et J. SV. PROCHÁZKA. L'if, surtout dans les régions de la Tchécoslovaquie.** [Taxus in Czecho-Slovakia.] *Sborník Československe Akad. Zěmědelské (Ann. Czech. Acad. Agric.)* 3: 299-384. 1928. —In Czecho-Slovakia, *Taxus* is no longer uniformly distributed. In the Carpathians it is found quite frequently. It is curious that in western Czecho-Slovakia it is the lowland type up to 700 m., whereas in the east it is the subalpine type up to 1300 m. In the Carpathians its occurrence is not strictly local as in Bohemia, Moravia and Silesia, the forests of the Carpathians being for the most part in a primitive state. In Slovakia, *Taxus* is found chiefly on limestone containing about 80% $CaCO_3$. *A. Pilát (transl. by J. Kittredge, Jr.).*

11117. **PRICE, W. R. On the distribution of Pseudolarix fortunei, the golden larch.** *Kew Bull. Misc. Inform.* 1931(2): 67-68. 1931.—Gives an up to date account of the distribution in China.—*A. D. Cotton.*

ANGIOSPERMAE (MIXED)

11118. **BOLUS, L. Novitates Africanae.** *Jour. Bot.* 66(781): 9-15; (787): 195-200. 1 fig.; (788): 229-233. 1928.—Oxalidaceae: *Oxalis* **crassipes** (p. 9); *O.* **pageae** (p. 10); *O.* **subsessilis** (p. 10). Aizoaceae: *Mesembrianthemum* **pachyphyllum** (p. 11); *M.* **longifolium** (p. 196); *Delosperma* **lavisiae** (p. 11), Orange Free State; *D.* **parviflorum** (p. 230); *Ruschia* **albiflora** (p. 12); *R.* **parvifolia** (p. 12); *R.* **dyeri** (p. 230); *R.* **framesii** (p. 231); *R.* **triquetra** (p. 231); *R.* **inconspicua** (p. 232); *Aridaria* **serotina** (p. 196); *Leipoldtia* **uniflora** (p. 13); *Cephalophyllum* **rigidum** (p. 198); *Hereroa* **fimbriata** (p. 198); *H.* **latipetala** (p. 199); *H.* **calycina** (p. 200); *H.* **concava** (p. 200); *H.* **teretifolia** (p. 229). Iridaceae: *Gladiolus* **robertsoniae** Bolus f. (p. 13), Orange Free State; *G.* **patersoniae** Bolus f. (p. 14). Liliaceae: *Aloe* **pillansii** L. Guthrie (p. 15); *A.* **karasbergensis** Pillans (p. 233), South West Africa and Cape Province. Umbelliferae: *Hermas* **pillansii*** C. Norman (p. 195). Y. Sandwith.*

MONOCOTYLEDONES

11124. **COLLINS, G. N. The phylogeny of maize.** *Bull. Torrey Bot. Club* 57(4): 199-210. 1930.—Discusses methods of tracing phylogeny and points out that man is the most important factor in evolution of maize. The differentiating characters of the genera *Tripsacum, Euchlaena* and *Zea* are given. Arranged in the order of their affinities with maize the series of related forms is: Mexican *Euchlaena,* Florida *Euchlaena, Euchlaena perennis,* and *Tripsacum.* The possible origin of domesticated maize is considered under: mutation, selection from *Euchlaena,* evolution from a form independent of *Euchlaena,* and hybridization between *Euchlaena* and some member of the Andropogoneae. None of the proposed methods is in complete accord with the facts, but the theory of hybrid origin is considered the most plausible.—*G. N. Collins.*

11125. **DANDY, J. E. Some new names in the Monocotyledones.-I.** *Jour. Bot.* 69(818): 53-55. 1931.—*Protolirion* **sakuraii** (*Miyoshia s.* Makino) (p. 53); *Manisuris* **sulcata** (*Peltophorus sulcatus* Stapf) (p. 54); *Hypogynium* **virgatum** (*Andropogon virgatus* Desv.) (p. 54); *Dybowskia* **dybowskii** (*Andropogon d.* Franch.) (p. 54); *Leucophrys* **psammophila** (*Panicum psammophilum* Welw.) (p. 54); *Urochloa* **mosambicensis** (*Panicum* **mosambicense** Hack.) (p. 54); *Acroceras* **zizanioides**

(*Panicum oryzoides* Sw. not Arduino) (p. 54); **OTTOCHLOA** (*Hemigymnia* Stapf, not Griff.) (p. 54); *O.* nodosa (*Panicum multinode* Presl, not Lam.) (p. 55); *O.* arnottiana (*Panicum arnottianum* Nees) (p. 55); *O.* fusca (*Hemigymnia f.* Ridl.) (p. 55); *O.* malabarica (*Poa m.* L.) (p. 55); *Cyrtococcum* chaetophoron (*Panicum c.* Roem. & Schult.) (p. 55). A full list of synonyms is given for each sp.—*A. L. Grant.*

11126. **FERNALD, M. L. Some rare plants of Scotland.** *Jour. Bot.* 69(817): 8-10. 1931.—Two plants unusual in Great Britain were found on a trip to Loch Maree. *Eriophorum opacum* (Björnstr.) Fernald had not been recorded from Great Britain, and *Scirpus hudsonianus* (Michx.) Fernald had been collected only from 1 station. Status of these spp., with notes on distinguishing characteristics and relationships, are included.—*A. L. Grant.*

11127. **JUMELLE, HENRI. Les Neophloga palmiers de Madagascar.** *Ann. Mus. Colonial Marseilles* 6(3): 5-47. 1928.—The author gives the distinguishing characteristics of the genus, a key based on spadix and leaf characters, and taxonomic descriptions of 22 spp. of *Neophloga*, including: *N.* integra (p. 13), *N.* simianensis (p. 13), *N.* lucens (p. 15), *N.* occidentalis (p. 24), *N.* montana (p. 29), *N.* lutea (p. 32), *N.* betamponensis (p. 33), *N.* mangorensis (p. 34), *N.* littoralis (p. 41), and *N.* lanceolata (p. 45).—*L. K. Henry.*

11128. **LOUSLEY, J. E. The Schoenoplectus group of the genus Scirpus in Britain.** *Jour. Bot.* 69(822): 151-163. 1931.—An extended account of the relationships, geographical distribution in Great Britain and hybrids within the group.—*A. L. Grant.*

11129. **PRAIN, D., and I. H. BURKILL.** Dioscorea: section Stenocorea. *Kew Bull. Misc. Inform.* 1931(2): 88-91. 1931.—A general account of the section, with a key to the 5 spp. included and a plan showing their geographical distribution. *D.* sumatrana (p. 90), Sumatra, is new.—*C. Fischer.*

11130. **SOÓ, RALPH. A new Himalayan Orchis.** *Jour. Bot.* 66(781): 15-17. 1 fig. 1928.—*Orchis* graggeriana (p. 15), India; *O. hatagirea* vars. schlaginweitii (p. 17), Tibet, doniana (p. 17), Tibet, and afghanica (p. 17), Afghan.—*A. L. Grant.*

11131. **STAERK, EBERHARD. Anleitung zur Bestimmung von Gräsern.** 36p. 32 pl. P. Parey: Berlin, 1926. Price, M 2.50.—The work is designed for the determination of grasses not in flower. A brief introduction and glossary is followed by a key to the principal economic grasses of Germany, using vegetative characters only. Each species is illustrated by an enlarged photograph showing sheaths, ligules, and blades. A second key is given to the common grasses of Germany, without illustration.—*A. Chase.*

11132. **TUTIN, T. G. Two Madeiran grasses.** *Jour. Bot.* 69(819): 80-81. 1931.—*Imperata cylindrica* Beauv. and *Agrostis olivetorum* Gren. & Godr. are reported for the first time from Madeira.—*A. L. Grant.*

DICOTYLEDONES

11133. **ANDRÉJEFF, W. Über die homologen Reihen der Formen der Stieleiche, Traubeneiche und Flaumeiche. [Homologous groups of forms of Quercus robur, Q. sessiliflora and Q. lanuginosa.]** *Mittzeil. Deutsch. Dendrol. Ges.* 41: 186-206. 17 fig. 1929.—A number of extensive descriptions are presented concerning variations of fruits, leaves, petioles, shape of the acorn, time of leaf- and flower development.—*J. C. Th. Uphof.*

11134. **BAILEY, CLARA MAURIE. The genus Peperomia in northeastern South America.** *Trans. Illinois State Acad. Sci.* 20: 41-55. 1927.—21 spp. are mentioned as having been reported from one or more of the three Guianas. Of these, the report of the occurrence of *P. circinata* is based on a specimen actually collected in Brazil, and the type specimen of *P. piperea* is not a Peperomia, but consisted of a spike of some *Piper* and leaves of an aroid. The other 19 spp. are fully described, and 2 keys, one based on vegetative characters and one on fruit characters, are provided. There is a bibliography containing all works referring to plants of this genus from the Guianas and an index to the spp. mentioned.—*T. D. Howe.*

11135. **BRANDT, TH. En för Sverige ny Cirsium-hybrid. [A Cirsium hybrid new to Sweden.]** *Bot. Notiser* 1930(6): 507. 1930.—*C. canum* × *oleraceum* in Malmöhus.—*H. K. Svenson.*

11136. **BULLOCK, A. A. The genus Kraussia.** *Kew Bull. Misc. Inform.* 1931(5): 254-257. 1931.—A history of the genus, which has been confused with *Tricalysia*, from which it is distinguished by a key. A key to the spp. of *Kraussia* follows, with an enumeration of the 3 spp., including *K. incerta* (p. 256), Transvaal, and *K.* speciosa (p. 256), Tanganyika Territory. A list of excluded spp. follows, with 3 of *Tricalysia* and 1 of *Tarenna.* —*A. A. Bullock.*

11137. **BUROLLET, P. A. Remarques sur quelques Synanthérées adventices.** *Bull. Soc. Bot. France* 76 (7/8): 758-764. 1929.—Discusses the appearances in France of *Galinsoga aristulata* Bicknell, *G. brachystephana* Regel, *G. parviflora* Cav., and *Siegesbeckia orientalis* L.—*J. P. Young.*

11139. **CAMUS, AIMÉE. Bétulacées.** In: **H. LECOMTE. Flore Générale Indo-Chine** 5(10): 1033-1041. 1 fig. 1931.—*Carpinus*, 3 spp., with key, *Betula alnoides* and *Alnus nepalensis.*—*E. D. Merrill.*

11140. **CANBY, MARGARET L. The genus Corethrogyne in Southern California.** *Bull. Southern California Acad. Sci.* 26(1): 8-16. 1927.—A revision of the varieties of *Corethrogyne filaginifolia* (H. & A.) Nutt. in Southern California, based on field studies and on material from Pomona, Harvard, Univ. of California, and other herbaria. The 11 varieties described include peirsoni (p. 14), typica (*C. f.* (H. A.) Nutt.) (p. 10), brevicula (*C. b.* Greene) (p. 12), incana (*C. i.* Nutt.) (p. 14), and sessilis (*C. s.* Greene) (p. 15). A key is given, and specimens cited.—*E. E. Stanford.*

11141. **CONARD, H. S., and CORNELIA CLARKE. The pubescence of Lithospermum canescens and L. gmelini.** *Proc. Iowa Acad. Sci.* 35: 111-112. 1928(1930).—By enlarged photographs of identical magnification (12×) the characteristic hairs are shown.—*H. S. Conard.*

11142. **CRAIB, W. G. Contributions to the flora of Siam. Additamentum XXX.** *Kew Bull. Misc. Inform.* 1931(4): 206-221. 1931.—*Gilibertia* siamensis (p. 206); *Viburnum* kerrii Geddes (p. 207); *V.* sessiliflorum Geddes (p. 207); *Nauclea* brunnea (p. 208); *Adina* dissimilis (p. 208); *A.* polycephaloides (p. 209); *Uncaria* glaucescens (p. 210); *Wendlandia* nobilis (p. 210); *Greenea* oblonga (p. 211); *G.* siamensis (p. 211); *Argostemma* condensum (p. 212); *A.* dispar (p. 213); *A.* fuscum (p. 213); *A.* lobulatum (p. 214); *A.* saxicolum (p. 215); *A.* septatum (p. 215); *Clarkella* siamensis (p. 216); *Hedyotis* betongensis (p. 216); *H.* corymbiformis Geddes (p. 217); *H.* cytisoides (p. 217); *H.* dawsoniana (p. 218); *H.* decora (p. 219); *H.* densa (p. 219); *H.* diversifolia Geddes (p. 220); *H.* garrettii (p. 220); *H.* geddesiana (p. 221).—*A. D. Cotton.*

11143. **CRAIB, W. G. Contributions to the flora of Siam. Additamentum XXXI.** *Kew Bull. Misc. Inform.* 1931(5): 275-280. 1931.—*Hedyotis* impedita (p. 276); *H.* lychnidifolia (p. 276); *H.* pitardiana (p. 277); *H.* punicea (p. 277); *H.* ridleyana (p. 278); *H.* sarmentosa (p. 278); *Chasalia* chartacea (p. 279); *C.* membranacea (p. 280); *C.* microphylla (p. 280).—*A. D. Cotton.*

11144. **EXELL, A. W., et al. Notes from the British Museum Herbarium.** *Jour. Bot.* 69(820): 98-102. 1 fig. 1931.—*Xylopia* talbotii (Annonaceae) (p. 98), Nigeria; *X.* otunga (p. 99), Cameroons; *Tisonia* whitei (Flacourtiaceae) (p. 99), Madagascar, and *Sarcosperma* kachinensis (*Combretum kachinense* King & Prain) (Sapotaceae) (p. 100) are described by Exell. *Eryngium* dorae* C. Norman (Umbelliferae) (p. 100), Uruguay. *Cyclophorus* lanceolatus Alston (*Acrostichum lanceolatum* L.) (Polypodiaceae) (p. 102).—*A. L. Grant.*

11145. **EXELL, A. W. The genera of Combretaceae.** *Jour. Bot.* 69(820): 113-120; (821): 121-128. 1931.—An

artificial key to the genera is given and a key to the genus *Quisqualis*. The latter is divided into 4 sections: COMBRETOPSIS (p. 120), CAMPYLOGYNE (p. 120), SPHALANTHUS (p. 121), EUQUISQUALIS (p. 123). *Quisqualis* hensii (*Combretum h.* Engl. & Diels) (p. 120); *Q. h.* var. genuina (p. 120), Belgian Congo; *Q. h.* var. pyriformis (*Combretum pyriforme* DeWild.) (p. 120); *Q.* exannulata (*Cacoucia e.* O. Hoffm.) (p. 121); *Q.* mussaendiflora (*Combretum mussaendiflorum* Engl. & Diels) (p. 121); *Q.* latialata (*Combretum latialatum* Engl.) (p. 121); *Q.* pellegriniana (*Combretum pellegrinianum* Exell); *Q.* littorea (*Cacoucia l.* Engl.) (p. 121); *Q.* conferta (*Sphalanthus confertus* Jack) (p. 122); *Q.* thorelii (p. 122), Indo-China; *Q.* parviflora (*Q. densiflora* var. *p.* Ridley) (p. 123).—*A. L. Grant.*

11146. **FRANCIS, W. D. Two Rutaceae from Queensland and New Guinea.** *Kew Bull. Misc. Inform.* 1931(4): 188-191. 1931.—The species passing under the name of *Evodia accedens* Bl. in Queensland is *E. elleryana* F. Muell. Of this are recognised: var. pilosa (*E. tetragona* var. *p.* Lauterb.) and var. tetragona (*E. t.* K. Schum.) (p. 189). The 1st variety is widely spread in Queensland and also occurs in New Guinea; the 2nd is frequent in New Guinea. The species known as *E. muelleri* Engl. was based on a mixture, the fruits being obtained from a sp. of *Acronychia;* it consequently becomes *Acronychia* muelleri n. comb. (p. 190), and an emended description is furnished. A table contrasts *Evodia elleryana* and *Acronychia muelleri.*—*V. S. Summerhayes.*

11147. **FRÖDERSTRÖM, HARALD. The genus Sedum L. A systematic essay. I.** *Acta Horti Gothoburgensis* 5(Suppl.): 1-75. 28 pl., 304 fig. 1930.—*S. primuloides* var. pleurogynanthum* (*S. pleurogynanthum* Hand.-Mzt.) (p. 24); *S. dumulosum* var. rendlei (*S. r.* Hamet) (p. 28); *S. quadrifidum* vars. fastigiatum* (*S. f.* Hook. f. & Thoms.), himalense* (*S. h.* D. Don), tibeticum* (*S. t.* Hook. f. & Thoms.) and bouvieri (*S. b.* Hamet) (p. 30-32); *S. crassipes* vars. stephani (*S. s.* Cham.) and cretini (*S. c.* Hamet) (p. 36); *S. roseum* vars. atropurpureum* (*S. a.* Turcz.) and polygamum* (*S. p.* Rydb.) (p. 39-40); *S. bupleuroides* vars. rotundatum (*S. r.* Hemsl.), discolor* (*S. d.* Franch.) and purpureoviride (*S. p.* Praeg.) (p. 44-45); *S. populifolium* var. notarjanni* (*S. n.* Ten.) (p. 58); *S. populifolium* × *ewersii** n. hybr. (p. 58).

11148. **FRÖMAN, INGMAR. Phyllitis, Helichrysum och Eryngium på Gotland. [Phyllitis, Helichrysum and Eryngium in Gotland, Sweden.]** *Bot. Notiser* 1930(3/4): 225-232. 3 fig. 1930.—The literature on the occurrence of *Phyllitis* in Sweden is briefly reviewed. At Ekese in Gotland the plants are very few in number and found only in fissures on inaccessible calcareous cliffs. Two photographs are included. Formerly the plant was more abundant, but all accessible specimens have long since been removed for garden planting. *Helichrysum arenarium,* supposed to be extinct in Gotland, was found in 1926 in Alskog parish. *Eryngium maritimum**, known previously from a few stations on the west coast, appeared in 1929 near Ljugarn on the east coast.—*H. K. Svenson.*

11149. **GAGNEPAIN. Pédaliacées.** In: **H. LECOMTE. Flore Gén. Indo-Chine** 4(5): 607-608. 1930(pars).—Two genera, *Pedalium* and *Sesamum.*—*E. D. Merrill.*

11150. **GATES, F. C., and DOROTHY J. CASHON. Star-thistle (Centaurea picris Pall.) a new weed in Kansas.** *Trans. Kans. Acad. Sci.* 31: 50. 1929.—Noting the appearance of *Centaurea picris* from the Caspian region into northeastern Kansas in 1921.—*F. C. Gates.*

11151. **GREENMAN, J. M. A new variety of Senecio aureus L.** *Ann. Missouri Bot. Gard.* 16(4): 405-406. 1 pl. 1929.—*Senecio aureus* var. ashei, Virginia (type) and Tennessee.—*B. McAvoy.*

11152. **HALL, L. B. Short notes.** *Jour. Bot.* 66(781): 24-26. 1928.—*Erica cinera* var. rendlei (p. 25), England.

11153. **HU, H. H. Notulae systematicae ad floram sinensem, III.** *Jour. Arnold Arboretum* 12(3): 151-156. 1931.—The hitherto unknown fruit of *Fagus lucida* Rehd. & Wils. is described, and the following from the province of Kwangsi proposed: *Hydrangea* kwangsiensis (p. 152), *Citrus* kwangsiensis (p. 153), *Acer* angustilobum (p. 154), *A. oblongum* v. macrocarpum (p. 154), *Rhododendron* minutiflorum (p. 155). *Porana sinensis* Hemsl. (=*Vatica cordata* Hu).—*A. Rehder.*

11154. **HUBER, ALWINE. Veronica L. I. Die Sektionen Pseudolysimachia Koch und Veronicastrum Benth. und die Gattung (Sektion) Leptandra Benth.** *Pflanzenareale* 2(4): 29-34. 9 maps. 1929.—Section *Leptandra* includes *Veronica virginica, V. sibirica* and *V. tubiflora* in eastern N. Amer. and eastern Asia; the disjunctional distribution shows the relatively great age of the group. Section *Pseudolysimachia* includes *V. grandis, V. laeta, V. pinnata, V. incana, V. spuria, V. spicata,* and *V. longifolia* with coherent distributions indicating that this is evidently a recently developed group. A composite range-map portrays the main area of distribution from the N. Balkan States through S. W. Russia to the Pacific Ocean. Section *Veronicastrum* includes 5 subgroups so strongly differentiated and of such wide and disjunctional distribution as to indicate the great age of the section. Stations for the 22 spp. are in Japan, western U. S. A. and Canada, east Canada, Greenland, Europe, central Asia, and isolated spots in central Africa. —*J. W. Gillespie.*

11155. **HUTCHINSON, J., et al. Tropical African plants: VIII.** *Kew Bull. Misc. Inform.* 1931(5): 270-275. 1931.—*Ricinodendron* tomentellum Hutch. et Bruce (p. 270), Kenya; *Dichapetalum* keniense Hutch. et Bruce (p. 270), Kenya; *Crotalaria* (*Simplicifoliae*) unicaulis Bullock (p. 271), Northern Rhodesia; *Loranthus* (*Longicalyculati*) acacietorum Bullock (p. 271), *Cussonia* jatrophoides Hutch. et Bruce (p. 273), *Lagynias* pallidiflora Bullock (p. 273), *Tecomaria* rupium Bullock (p. 274) and *Leucas* (*Astrodon*) pododiskos Bullock (p. 275), all from Tanganyika; *Aporrhiza nitida* Gilg, amplified description; *Lagynias* lasiantha Bullock (*Pachystigma lasianthum* Sond.) (p. 274); *Mimulopsis* glandulosa Bullock (*Epiclastopelma glandulosum* Lindau) (p. 275).—*A. D. Cotton.*

11156. **JÁVORKA, ALEXANDER. Hungarian species of Onosma.** (English translation by C. C. Lacaita.) *Jour. Bot.* 66(781): 1-9. 1928.—A translation of a paper appearing in *Ann. Mus. Nation. Hungaricii* in 1906.

11157. **KLOOS, A. W. Jr. Het Geslacht Thymus in Nederland. [The genus Thymus in Netherlands.]** *Verslag. en Mededeel. Nederlandsche Bot. Ver.* 1925: 276-337. 14 fig. 1926.—A synopsis of the genus. A brief discussion of the characters is followed by a detailed one of ancient literature and synonyms, especially on the names *T. serpyllum, T. chamaedrys,* and *T. pulegioides.* A key is provided to the Dutch forms of *T. serpyllum* L. (sens. ampl.) arranged in 2 well-defined spp.: *T. chamaedrys* Fr. and *T. angustifolius* Pers. and their hybrid *T. celakovskyanus* M. Schulze. Other sections of the paper deal with: (1) *T. chamaedrys* Fr. and its forms (*ovatus* Mill., *glaber* Mill., *praelongus* Briquet and *confusus* Briquet); (2) *T. angustifolius* Pers. and its forms (*silvicola* W. et Gr., *linearifolius* W. et Gr., *curvifolius* W. et Gr., *rigidus* W. et Gr., *ericoides* W. et Gr., and *empetroides* W. et Gr., of each of which a photograph is reproduced); (3) *T. celakovskyanus* M. Schulze; (4) some monstrosities; (5) cultivated and introduced forms such as *T. lanuginosus* Mill., *T. splendens* Hort., *T. britannicus* Ronn., *T. vulgaris* L., *T. citriodorus* Pers. (with photographs of the specimen in Herb. Persoon). The last section gives a summary with 2 maps of the localities where *T. chamaedrys* and *T. angustifolius* are found in the Netherlands.—*A. W. Kloos, Jr.*

11158. **LABRIE, J. "Rosa gallica" et ses sous-espèces en Gironde.** *Actes Soc. Linn. Bordeaux, Proc.-Verb.* 80: 31-36. 1 fig. 1928.—The author discusses the distinguishing characters and the distribution of local forms of *Rosa,* none of which are considered indigenous.

11159. **LEANDRI, J. Cératophyllacées.** In: **H. LECOMTE. Flore Générale Indo-Chine** 5(10): 1052.

1 fig. 1931.—A single species, *Ceratophyllum demersum** L.—*E. D. Merrill.*

11160. **LECOMTE, H.** Sapotacées. Flore Générale Indo-Chine 3(7): 877-915. 1930.—Ten genera are recognized, the largest being *Sideroxylon* with 11 spp. *Mimusops elengi* v. poilanei (p. 880); *Manilkara* hexandra (*Mimusops h.* Roxb.) (p. 881); *Eberhardtia krempfii* v. magnifica (p. 884); *Sideroxylon wightianum* v. ballansae (p. 887); *S.* racemosum (*Planchonella racemosa* Pierre) (p. 888), and var. subracemosum (p. 889); *S.* baranense (p. 889); *S.* clemensii (p. 890); *S.* annamense (*Planchonella annamensis* Pierre) (p. 892); *S. ferrugineum* v. poilanei (p. 893); *S. hookeri* v. mekongense (p. 893); *S. cambodianum* v. thorelii (p. 894); *S.* bonianum (*Planchonella boniana* Dubard) (p. 894); *S.* eburneum A. Chev. (p. 895); *Donella roxburghii* var. tonkinensis (p. 898); *Palaquium* poilanei (p. 900); *P.* annamense (p. 900); *Bassia* alpina A. Chev. (p. 907); *Payena* annamensis (p. 909); *P.* floribunda (*Dasyaulus floribundus* Pierre) (p. 910); *P.* cambodiana (p. 912); *P.* elliptica (*Dasyaulus ellipticus* Pierre) (p. 913); *Sarcosperma* tonkinense (p. 914).—*E. D. Merrill.*

11161. **LECOMTE, HENRI.** Ébénacées. Flore Gén. Indo-Chine 3(7): 915-987. 11 fig. 1930.—Two genera are admitted, *Diospyros* with 64 and *Maba* with 7 spp., for which keys to genera and species are provided. *Diospyros ehretioides* vars. aho and harmandii (p. 925); *D. oocarpa* var. attopeuensis (p. 929); *D. eugenii* vars. laotica and tonkinensis (p. 934); *D.* bejaudii (p. 936); *D. odoratissima* vars. oblonga and pseudoebenoides (p. 940); *D. cordifolia* var. oblongifolia (p. 941); *D. nitida* var. peralata (p. 942); *D.* magnifica (p. 942); *D.* fleuryana A. Chev. (p. 948) and var. coriacea H. Lec. (p. 948); *D. dasyphylla* var. oblongifolia (p. 950); *D. eriantha* vars. balansae, fragrans, conica and latifolia (p. 952); *D.* cambodiana (p. 953); *D.* phanrangensis (p. 956); *D. embryopteris* var. siamensis (p. 958) and var. thirung (p. 959); *D. decandra* vars. laosiana and tigrina (p. 962); *D. baranensis* v. thoreliana (p. 964); *Maba* nebulorum (p. 978).—*E. D. Merrill.*

11162. **MACBRIDE, J. FRANCIS.** Various spermatophytes. *Field Mus. Nat. Hist. Publ. 244. Bot. Ser.* 4(5): 99-124. 1927.—The following new species, varieties, form and combinations are by Macbride unless otherwise stated and the new plants are Peruvian except where a different locality is indicated: *Parosela* trichocalyx (*Dalea t.* Ulbrich) (p. 102); *P.* exilis (*Dalea e.* DC.) (p. 103); *P. microphylla* var. brevis (p. 103); *P.* vicina (p. 103); *P.* galbina (p. 104); *P.* calocalyx (*Dalea c.* Ulbrich) (p. 104); *P.* sulfurea (*Dalea s.* Ulbrich) (p. 104); *P.* weberbaueri (*Dalea w.* Ulbrich) (p. 105); *P.* sericophylla (*Dalea s.* Ulbrich) (p. 105); *P. humifusa* var. anatona (p. 105), Ecuador; *P.* catatona (p. 105); *P.* peruviana (p. 106); *P. boliviana* var. herrerae (p. 106); *P.* pennellii (p. 107); *P.* azurea (*Psoralea a.* Phil.) (p. 107); *P.* hofstenii (*Dalea h.* Fries) (p. 108); *P.* myriadenia (*Dalea m.* Ulbrich) (p. 108); *P.* onobrychis (*Dalea o.* DC.) (p. 108); *P.* eosina (p. 109), Bolivia; *P.* onobrychoides (*Dalea o.* Griseb.) (p. 109); *P.* elegans (*Dalea e.* Gillies) (p. 109); *P.* astragalina (*Dalea a.* HBK.) (p. 109); *P.* nova (*Dalea n.* Ulbrich) (p. 110); *P.* killipii (p. 110), Ecuador: *P.* fieldii (p. 111); *P.* rubricaulis (*Dalea r.* Ulbrich) (p. 112); *P.* kuntzei (*Dalea k.* Harms) (p. 112); *P.* jamesonii (p. 112), Ecuador; *Psoralea* remotiflora (p. 113); *Calacinum* axillare (*Polygonum a.* Hook. f.) (p. 115); *C.* complexum (*Polygonum c.* A. Cunn.) (p. 115); *C.* diclinum (*Polygonum d.* F. Muell.) (p. 115); *C.* ephedrioides (*Muehlenbeckia e.* Hook. f.) (p. 115); *C.* platycladum (*Polygonum p.* F. Muell.) (p. 115); *C.* fruticulosum (*Polygonum f.* Walp.) (p. 115); *C.* volcanicum (*Polygonum v.* Benth.) (p. 115); *C.* sagittifolium (*Coccoloba sagittifolia* Ort.) (p. 116); *C.* hastulatum (*Rumex hastulatus* Smith) (p. 116); *C.* chilense (*Muehlenbeckia chilensis* Meisn.) (p. 116); *C.* tamnifolium (*Polygonum t.* HBK.) (p. 116); *C.* leptobotrys (*Muehlenbeckia l.* Meisn.) (p. 116); *C.* tiliaefolia (*Muehlenbeckia t.* Wedd.) (p. 117); *C.* peruvianum (*Muehlenbeckia peruviana* Meisn.) (p. 117); *Malesherbia* ardens (p. 117); *M.* turbinea (p. 118); *Allocarya* kunthii (*Anchusa k.* Walp.) (p. 119); *A.* pygmaea (*Anchusa p.* HBK.) (p. 119); *A.* congesta (*Eritrichium humile* var. *congestum* Wedd.) (p. 119); *Liatris scariosa* f. benkei (p. 124), Indiana. The publication consists of 6 papers: The Perennial South American Paroselas; Further Peruvian Psoraleas; An Earlier Name for *Muehlenbeckia;* New Peruvian Malesherbias; A Defense of *Allocarya;* and Notes on *Cucumis, Palafoxia, Liatris.* The 1st is a revision of this group of *Parosela,* with an artificial key to spp., descriptions of new spp. and varieties and references to earlier described spp. The 3rd gives the author's reasons for taking up *Calacinum* in place of *Muehlenbeckia* and makes the necessary n. combs. The 5th is a detailed presentation of the author's arguments for maintaining *Allocarya* as a genus distinct from *Plagiobothrys* and gives a key for the separation of the two genera. The titles of the other papers indicate their contents.

11163. **MACKLIN, E. D.** The Casuarina distyla complex. *Kew Bull. Misc. Inform.* 1931(3): 145-151. 1931.—A short discussion of previous work on the group is followed by a key to the 7 spp. recognized, which are enumerated with citations of all specimens seen, including all those at Kew and at the British Museum. *C.* paradoxa (p. 150), Australia, is keyed out and placed in the enumeration; complete description and citation of records will follow.—*V. S. Summerhayes.*

11164. **McMINN, HOWARD E.** A geographic and taxonomic study of the California species of the genus Ceanothus. *Contr. Dudley Herb. Stanford Univ.* 1(4): 121-147. Map. 1 pl. 1930.—An account of 35 spp. with descriptive key, 3 phylogenetic charts of the *Euceanothus* section, a geographical and phylogenetic chart of the *Cerastes* section in California, indicating the probable origin and migration of the various species, and plate showing character differences between the *Euceanothus* and *Cerastes* sections. No new spp. are described. All doubtful forms are listed under the heading variations, there to remain until further results from field and transplant experiments are obtainable. Cross section preparations from leaves of all spp. of the *Cerastes* section show the stomata located in sunken pits on the under side of the leaves while sections of leaves of the *Euceanothus* sections show the stomata in the lower epidermis. The distribution of spp. is listed by counties. —*H. E. McMinn.*

11165. **MARQUAND, C. V. B.** New Asiatic gentians II. *Kew Bull. Misc. Inform.* 1931(2): 68-88. 1931.—An outline of the author's reclassification is given. The genus *Crawfurdia* is sunk in *Gentiana,* which latter is limited by the segregation as a separate genus of *Gentianella,* so that the following are included: *Gentiana* heleni n. nom. (*Crawfurdia trailiana* Forrest) (p. 69); *G.* fratri n. nom. (*C. delavayi* Franch.) (p. 70); *G.* khamensis n. nom. (*C. thibetica* Franch.) (p. 70); *G.* fascicularis n. nom. (*C. fasciculata* Wall) (p. 70); *G.* kingdonii n. nom. (*C. wardii* Marquand) (p. 70); *G.* confusa n. nom. (*C. affinis* C. B. Clarke) (p. 70); *G.* golowninia n. nom. (*C. japonica* Sieb. et Zucc.) (p. 70); *G.* speciosa (*C. s.* Wall.) (p. 70); *G.* angustata (*C. a.* C. B. Clarke) (p. 70); *G.* bulleyana (*C. b.* Forrest) (p. 70); *G.* campanulacea (*C. c.* Wall. et Griff.) (p. 70); *G.* luteoviridis (*C. l.-v.* C. B. Clarke) p. 70; *G.* eurycolpa (p. 71); *G.* discoidea (p. 72); *G.* crawfurdioides (p. 72), Tibet, with var. macrophylla (p. 73), Tibet and Burma; *G.* bomareoides (p. 73), Burma; *G.* sinkuensis (p. 73), Burma; *G.* iochroa (p. 74), Tibet; *G.* curviflora (p. 74); *G.* semialata (p. 75); *G.* membranacea (p. 75), Burma; *G.* pricei (p. 75); *G.* sessiliflora (p. 76); *G.* nienkui (p. 76); *G.* dimidiata (p. 77); *G.* cordata (p. 77); *G.* caudata (p. 78); *G. golowninia* var. oblonga (p. 79); *G.* dendrologi (p. 79); *G.* wutaiensis (p. 80); *G.* wasenensis (p. 80); *G.* subocculta (p. 81), China and Tibet; *G. hexaphylla* var. caudata (p. 81); *G. arethusae* vars. delicatula (p. 81), Tibet, and rotundatolobata (p. 82); *G.* emergens (p.

82); *G. trichotoma* var. brevicaulis (p. 82); *G.* chingii (p. 83); *G.* gilvostriata (p. 83), Burma; *G. handeliana* var. brevisepala (p. 84), Burma; *G. veitchiorum* var. caelestis (p. 84); *G. sino-ornata* var. punctata (p. 84), Burma; *G.* choanantha (p. 85); *G. pedicellata* var. chingii (p. 85); *G.* macraucena (p. 85), Tibet; *G.* moniliformis (p. 86), Tibet; *G.* parryae (p. 86), India; *G.* subuniflora (p. 87); *G.* radiata (p. 87); *G.* anisostemon (p. 88). New material is from China if not otherwise stated.—*C. V. B. Marquand.*

11166. MOSS, C. E. Pleiosepalum, a new genus of Caryophyllaceae. *Jour. Bot.* 69(819): 65-67. 1 pl. 1931.—PLEIOSEPALUM (Polycarpeae) (p. 65), genotype *P.* mosambicinum* (p. 65), from near Lourenco Marques, Portuguese East Africa.—*A. L. Grant.*

11167. PELLEGRIN, F. Lentibulariacées (Utriculariacées). In: H. LECOMTE. Flore Générale Indo-Chine 4(5): 467-487. 3 fig. 1930.—A single genus (*Utricularia*) with 26 spp., including *U.* evrardii (p. 476); *U. delphinioides* v. minor (p. 477); *U. hirta* v. elongata (p. 480); *U. brevilabris* v. parviflora (p. 481); *U. filicaulis* v. papillosa (p. 486). Key to spp. is given.—*E. D. Merrill.*

11168. PELLEGRIN, F. Gesnéracées (Cyrtandrées). In: H. LECOMTE. Flore Gén. Indo-Chine 4(5): 487-565. 6 fig. 1930.—22 genera are admitted, the larger ones being *Aeschynanthus* (12 spp.), *Didymocarpus* (10), *Chirita* (18), and *Boea* (14). *Aeschynanthus* hosseusii (*A. macrocalyx* Hosseus, non Clarke) (p. 498); *Lysionotus* petelotii (p. 503); *Didissandra* annamensis (p. 509); *D.* evrardi (p. 510); *D.* petelotii (p. 511); *D.* clemensiae (p. 511); *Oreocharis aurea* v. nana (p. 513); *Boeica* confertiflora (*Didissandra c.* Drake) (p. 517); *Didymocarpus* poilanei (p. 523); *Chirita* geoffrayi (p. 528); *C.* annamensis (p. 530); *C.* semicontorta (p. 531); *C. poilanei* v. villosa (p. 534); *Boea* martini H. Lév. (p. 543); *B. multiflora* v. villosa (p. 549); *B.* evrardii (p. 550); *Petrocosmea* condorensis (*Didymocarpus c.* Pierre) (p. 555) *Damrongia* kerrii (*Petrocosmea k.* Craib) (p 556).—*E. D. Merrill.*

11169. PITARD, J. Myrsinacées (fin). In: H. LECOMTE. Flore Générale Indo-Chine 3(7): 808-887. 3 fig. 1930.—The genera *Ardisia* with 77 spp. and *Aegiceras* with 1 sp. are considered. Included are: *Ardisia* myrsinoides (p. 809); *A.* argentea* (p. 810); *A.* nigropilosa (p. 810); *A.* ramondiaeformis (p. 812); *A.* velutina (p. 813); *A.* albomaculata (p. 813); *A.* glauca (p. 814); *A. kteniophylla* v. microdonta (p. 815); *A.* sylvestris (p. 816); *A.* micranthera (p. 817); *A.* tinctoria (p. 817) with v. microcarpa (p. 818); *A.* psychotriaephylla (p. 818); *A.* garcinifolia (p. 819); *A.* pseudo-pedunculosa (p. 820) with vars. cochinchinensis, montana and macrocarpa (p. 821); *A.* viburnifolia (p. 821); *A.* lecomtei (p. 822); *A.* melastomoides (p. 822); *A.* calophylloides (p. 823); *A.* cambodiana Pierre mss. (p. 824); *A.* evrardii (p. 825); *A.* quinquegona vars. latifolia, linearifolia and micrantha (p. 827); *A.* incrassata (p. 832); *A.* graciliflora (p. 832); *A.* florida (p. 833); *A.* capillipes (p. 834); *A.* lauriformis (p. 835); *A.* splendens (p. 836); *A. rigida* v. chevalieri (p. 838); *A.* poilanei (p. 838); *A.* chevalieri (p. 840); *A.* macrosepala (p. 840) with v. crenata (p. 841); *A.* smaragdina (p. 841); *A.* sauraujaefolia (p. 842); *A.* recliniflora (p. 842); *A.* ixoraefolia (p. 843); *A.* expansa (p. 844); *A.* maxima (p. 845); *A.* helferiana v. septentrionalis (p. 846); *A.* albiflora (p. 847); *A.* villosula (p. 847); *A. humilis* v. parvifolia (p. 849); *A.* penduliflora (p. 849); *A. amherstiana* v. annamensis (p. 851); *A. oxyphylla* v. cochinchinensis (p. 851); *A.* dinhensis (p. 852); *A.* mirabilis (p. 858); *A.* harmandii Pierre ms. (p. 859); *A.* annamensis (p. 859); *A.* nemorosa (p. 860); *A.* aciphylla (p. 861); *A.* stellifera (p. 863); *A.* mouretii (p. 864); *A.* evonymifolia (p. 865); *A.* roseiflora (p. 866); *A. virens* v. annamensis (p. 868); *A.* thorelii (p. 869) with v. latifolia (p. 870); *A.* miniata (p. 870); *A.* incarnata (p. 871); *A.* pseudocrispa (p. 871); *A. patens* v. tonkinensis (p. 872); *A.* rubescens (p. 873).—*E. D. Merrill.*

11170. RIDLEY, H. N. Additions to the flora of Borneo and other Malay islands. *Kew. Bull. Misc. Inform.* 1931(1): 33-39. 1931.—Enumerates 4 spp. not reported previously from these islands and describes the following: *Olax* rosea (p. 33); *O.* multiflora (p. 34), Celebes; *O.* laxiflora (p. 34), Kei Islands; *Ilex* orestes (p. 35); *Euonymus* castaneifolius (p. 36); *E.* moultoni (p. 36); *Microtropis* rigida (p. 36); *Lophopetalum* sessilifolium (p. 37); *L.* subsessile (p. 37); *L.* havilandii (p. 37); *L.* rigidum (p. 38); *L.* multinervium (p. 39); *L. beccarianum* Pierre; *Ochanostachys amentacea* v. rufa (p. 35); *Iodes reticulata* v. glabrescens (p. 35). All are from Borneo unless otherwise stated.—*C. Fischer.*

11171. ROBYNS, W. Vangueriae Gossweilerianae. *Jour. Bot.* 69(822): 165-172; (823): 185-191. 1931.—*Fadogia* punctulata (p. 166), *F.* caespitosa (p. 167), *F.* variifolia (p. 167), *F.* olivacea (p. 168), *F.* flaviflora (p. 169), *F.* oblongo-lanceolata (p. 170), *F.* gossweileri (p. 171), *Tapiphyllum* gossweileri (p. 185), *T.* fulvum (p. 186), *T.* molle (p. 186) and *Canthium* apiculatifolium (*Plectronia apiculatifolia* DeWild.) (p. 190), all from Angola; *Rytigynia* mayumbensis (p. 187), *R.* gossweileri (p. 188) and *Vangueriopsis* gossweileri (p. 189) from Portuguese Congo. *Fadogia punctulata* was collected by d'Anchieta, the others by Gossweiler.—*A. L. Grant.*

11172. ROUSH, EVA M. FLING. A synopsis of Robinsonella. *Jour. Arnold Arboretum* 12(1): 49-59. 7 fig. 1931.—Seven spp. are recognized and described, with full citation of literature and of specimens examined. A key precedes the descriptions. The figures represent outlines of leaves.—*A. Rehder.*

11173. SANDWITH, N. Y. Contributions to the flora of Tropical America. IV. The Baromallis of British Guiana. *Kew Bull. Misc. Inform.* 1931(1): 46-61. 1931.—2 spp. of *Catostemma* which have been passing under the Arawak vernacular name *Baromalli* are fully described and the differences discussed at length. One of the two is *C.* commune (p. 51).—*N. Y. Sandwith.*

11174. SMITH, C. A. Further notes on Lachnopylis. *Kew Bull. Misc. Inform.* 1931(1): 39-41. 1931.—*L.* flocculosa (p. 40), Angola; *L.* compacta (p. 40), Anglo Egyptian Sudan; *L.* scytophylla (p. 39), Madagascar—*A. D. Cotton.*

11175. SMITH, C. A. A new Harveya from the Transvaal highveld. *Kew Bull. Misc. Inform.* 1931(2): 65-67. 1 pl. 1931.—*Harveya* anisodonta*.—*A. D. Cotton.*

11176. SMITH, C. A. Palmstruckia of the Flora Capensis. *Kew Bull. Misc. Inform.* 1931(3): 154-156. 1931.—This is shown to be an invalid name; THLASPEOCARPA (Cruciferae) n. nom. (p. 155) (*Palmstruckia* Sond., not Retz.) is proposed to replace it. *T.* capensis (*Palmstruckia c.* Sond.) (p. 155) is made for this monotypic genus, and full synonymy is given. Confusion with *Peltaria capensis* Linn. f. is pointed out and for the latter *Heliophila* capensis n. comb. (p. 155) is proposed.—*A. A. Bullock.*

11177. SMITH, C. A. Suggested conservation of Pollichia. *Kew Bull. Misc. Inform.* 1931(4): 198. 1931.—*Pollichia* Dryand. (1789) has been maintained in many standard works, for the last 140 years, in preference to *Meerburghia* Moench. (1802), and *Pollichia* Medic. (1783) is rejected in favor of *Trichodesma* R. Br. It is therefore proposed that *Pollichia* Dryand. be conserved.—*A. A. Bullock.*

11178. SPRAGUE, T. A. The botanical name of "Tara." *Kew Bull. Misc. Inform.* 1931(2): 91-96. 1931.—"Tara" is a small tree or shrub, the legumes of which are used in tanning. It is a native of Peru, Bolivia, Ecuador, Colombia and Venezuela, and is cultivated in Chile. It is commonly known under the synonyms *Caesalpinia tinctoria* (H. B. K.) Taub. or *C. pectinata* Cav., but its name under International Rules is *C. spinosa* (Mol.) Kuntze.—*T. A. Sprague.*

11179. STEARN, W. T. Notes from the University Herbarium, Cambridge, 1. A new Rhodesian Kalanchoe. *Jour. Bot.* 69(822): 164-165. 1931.—*Kalanchoe* aleurodes (p. 164).—*A. L. Grant.*

11180. STEENIS, C. G. G. J. van. A revision of the

Queensland Bignoniaceae. *Proc. Roy. Soc. Queensland* 41: 39-58. 2 fig. 1929.—This account of the Australian Bignoniaceae includes geographic relations, synonyms, descriptions of the genera and spp., keys to genera and spp., and distribution of the spp. (cited materials). **HAUSSMANNIANTHES** (p. 50), n. n. for *Haussmannia* F. v. M., not Dunker, with *Haussmannianthes jacunda* (*Haussmannia j.* F. v. M.) (p. 51), is proposed.—*C. G. G. J. van Steenis.*

11181. **TADULINGAM, C., and K. CHERIYAN JACOB.** A new species of Senecio. *Jour. Indian Bot. Soc.* 9(1): 40-41. 2 pl. 1930.—*Senecio* **ansteadi*** (p. 40), closely allied to *S. corymbosus**, from the Tinnevelly Hills (3000 ft.), S. India.—*W. Dudgeon.*

11182. **TURESSON, GÖTE.** Zur Frage nach der Spontaneität von Betonica officinalis L. in Schweden. *Bot. Notiser* 1930(6): 495-506. 2 fig. 1930.—Four series of plants raised from seeds from south Sweden were compared with 3 similar series from middle Europe (Munich, Vienna, and Agram) and a transplantation series from Moscow. Two of the south Swedish groups showed hereditary dwarfness and early-flowering as compared with the middle European series; the other series from south Sweden had comparative tallness and was late-blooming. The moscow series combined hereditary tall growth and early-flowering. Turesson 1930 showed that many identical species of summer-blooming plants of Europe have dwarfed early-flowering biotypes in the north and taller late-blooming biotypes in southern Europe. Since the Stehag-Kungsmarken (Sweden) series of *B. officinalis* showed the hereditary dwarfish early-flowering combination characteristic of south Sweden, while the Malmö-Tapperöd series was tall and late-flowering as in the middle European type, it is concluded that the former series is spontaneous, the latter series introduced from middle or south Europe. It also is important to recognize that the south Swedish *Betonica officinalis* as represented by the Stehag-Kungsmarken series represents the north-European ecotype of the species.—*H. K. Svenson.*

11183. **VAN ESELTINE, G. P.** A preliminary study of the unicorn plants (Martyniaceae). *New York State* [*Geneva*] *Agric. Exp. Sta. Tech. Bull.* 149. 1-41. 15 fig. 1929.—A systematic study of the family Martyniaceae, based largely on the collections of the U. S. Nat. Herb. and those of the Missouri Bot. Gard. Five genera are recognized: *Craniolaria, Holoregmia, Proboscidea, Ibicella,* and *Martynia.* Several new names result: *Proboscidea* subg. **DISSOLOPHIA** (p. 12), and subg. *Eu-Proboscidea* Stapf, emended description; *Proboscidea* **confusa*** (p. 12), Mexico; *P.* **peruviana*** (p. 17), Peru; *P.* **sinaloensis*** (p. 24), Mexico; **IBICELLA** (p. 31), (*Proboscidea* sect. *Ibicella* Stapf.); *I.* **nelsoniana*** (*Martynia lutea* var. *n.* Barb.-Rodr.) (p. 32); *I.* **lutea*** (*Martynia l.* Lindl.) (p. 34) (genotype). Keys to genera, subgenera, and species are given. *Proboscidea jussieui* Keller is shown to be the tenable name for the common unicorn plant. Notes on uses of the various species and directions for their culture are included.—*G. P. Van Eselline.*

FLORISTICS AND PLANT DISTRIBUTION

11184. **ARDAGH, J. Paul Hermann's Ceylon herbarium and icones.** *Jour. Bot.* 69(821): 137-138. 1931.—A short historical account of one of the most interesting of the old botanical collections in the Department of Botany, British Museum.—*A. L. Grant.*

11185. **BAUMANN, EUGEN. Beiträge zur Flora des Bodensees und des Rheingebietes.** *Mitteil. Thurgauischen Naturforsch. Ges.* 27: 145-154. 1928.—Because of the unusually warm season in 1928 the conditions were most favorable for the development of aquatic plants. The paper is largely devoted to an enumeration and discussion of various species, varieties, and forms from the standpoint of local distribution.—*E. D. Merrill.*

11186. **FISCHER, C. E. C. Contributions to the flora of Burma. IX.** *Kew Bull. Misc. Inform.* 1931(1): 26-29. 1931.—Lists 17 known spp. new to Burma, redescribes a hitherto little known species, *Ophiorrhiza erubescens,* and proposes *Vallaris* **anceps** (*Trachelospermum a.* Dunn & R.) (p. 28).—*C. Fischer.*

11187. **HASSLOW, O. J. Några ammärkningsvärda växtfynd från de senaste åren. [Noteworthy plants found in Sweden in recent years.]** *Bot. Notiser* 1930 (6): 508-509. 1930.—*Sanguisorba minor* Scop. and *Euphrasia suecica* Murb. & Wettst. in Öland; *Medicago minima* Desv., *Hirschfeldia pollichii* and *Arctium* hybrids (*A. nemorosum* × *tomentosum, A. minus* × *nemorosum*) in Skåne. An additional locality for the liverwort *Jungermannia confertifolia* (Schiffn.) Arn. is noted in Jämtland. *Grimmia stirtonii* Schimp., a new moss sp. for Sweden, was found by the late S. Medelius near Malmö.—*H. K. Svenson.*

11188. **HUTCHINSON, J. The flora of the Libyan Desert.** *Kew Bull. Misc. Inform.* 1931(4): 161-166. 1931.—A short account of the vegetation of the area covered by the itinerary Cairo-Baharia-Owenat-Selima-Halfa-Kharga, contained in a letter to Kew from W. B. K. Shaw, who accompanied Major R. A. Bagnold's 1930 expedition; this is followed by a list of the spp. he collected, with notes on their distribution. 21 spp. of angiosperms and gymnosperms, representing 14 families, are included. All are comparatively well-known plants of Engler's North African and Indian Desert Region.—*A. A. Bullock.*

11189. **HUTCHINSON, J. General Smuts' botanical expedition to Northern Rhodesia, 1930.** *Kew Bull. Misc. Inform.* 1931(5): 225-254. 3 maps., 6 fig. 1931.—A general account of the country traversed by the expedition, through Rhodesia, with some mention of the more interesting plants met with; the maps indicate distribution of *Copaifera mopane** Kirk, *Pteronia,* including *P.* **smutsii*** (p. 250), and *Parinarium curatellaefolium* Planch. Other n. spp. are: *Artabotrys* **collinus** (p. 245); *Nymphaea* **primulina** (p. 245); *N.* **divaricata*** (p. 246); *Monotes* **cordatus** (p. 246); *M.* **glandulosissimus** (p. 246); *M.* **lukuluensis** (p. 246); *M.* **obliquinervis** (p. 247); *M.* **oblongifolius** (p. 248); *M.* **tomentellus** (p. 248); *Ochthocosmus* **gillettae** (p. 249); *Faurea* **argentea*** (p. 249); *Cryptosepalum* **fruticosum** (p. 250); *Pteronia* **smutsii*** (p. 250); *Aster* **brevipedunculatus** (p. 250); *Cineraria* **monticola** (p. 251). A key, and enumeration of the 13 Rhodesian spp. of *Monotes* concludes the paper.—*A. A. Bullock.*

11190. **INGWERSEN, W. E. TH. Plant hunting on the Thessalian Olympus.** [Concluded.] *Gard. Chron.* [*London*] 87(2248): 68-69. 2 fig. 1930.

11191. **KIRKWOOD, JOSEPH EDWARD. Northern Rocky Mountain trees and shrubs.** xvii+340p. 35 pl., 87 fig. Stanford University Press: Stanford University, California. 1930.—Pr. $7.50.—A non-technical book, on the woody flora of the region from the Yellowstone Park north and west through Montana, Idaho, and the Canadian Rockies, primarily designed for the general public but also planned to serve the technical botanist and forester. The non-cultivated woody plants of the area treated include 27 families, 79 genera, and 248 species. Of these the gymnosperms (2 families, 9 genera, 24 species—less than 10 per cent of the species) constitute nearly all the forests of the region. Keys are given to families, genera, and species. The specific descriptions are largely based upon the field observation of the author. The characters of each genus are illustrated in original figures, while there are photographic reproductions of a number of species. The general distribution of each species is indicated with mention of a few localities in the region. Outstanding features and the general utility of each species are discussed. There is a short appendix on botanical terminology (illustrated).—*W. C. Muenscher.*

11192. **McATEE, W. L. Seventh supplement to the flora of the District of Columbia and vicinity.** *Proc. Biol. Soc. Washington* 43: 21-54. 1930.—Additions and corrections to the floral record since 1919.—*W. L. McAtee.*

11193. **WALKER, EGBERT H. Fifty-one common orna-**

mental trees of the Lingnan University campus. *Lingnan Sci. Jour.* 6(1/2): 1-166. 54 fig. 1928.—The descriptions of the 51 spp., chiefly subtropical or tropical, are preceded by chapters on the morphology of trees with illustrations, on the planting of trees, by a key to the genera and a systematic list of all trees on the campus. Each species is fully described, with additional general remarks chiefly on its economical uses, and is illustrated by drawings of flowering and fruiting branches with analytical figures (except the palms, of which habit figures are given). A glossary and indices conclude the paper.—*A. Rehder.*

MORPHOLOGY AND ANATOMY OF VASCULAR PLANTS

ARTHUR J. EAMES, *Editor*

(See also in this issue Entries 9135, 9143, 9146, 9161, 9323, 9326, 11141, 11217, 11223, 11226, 11227, 11423)

11194. AYYANGAR, R. L. NARASIMHA. A note on the determination of the area of surface of cotton seeds. *Madras Agric. Dept. Year Book* 1929: 7-15. 1930.—The calculation of the area of surface either from the volume or weight of the seed has been shown to be defective. Cotton seeds were immersed in liquid paraffin for 5 min. and centrifuged for 10 min. to remove excess of liquid. The increase in weight, other things being equal, should be proportional to the area of surface of the seeds. The error has been found to be low.

11195. BIRAGHI, A. Impollinazioni tra Nicotiana rustica var. brasilia ♀ e Petunia sp. ♂ e loro effetti. [Pollinations between N. rustica var. brasilia ♀ and Petunia sp. ♂ and their effects.] *Ann. Bot.* [*Rome*] 18 (2): 216-222. 1929.—Pollen of *Petunia* germinates normally on *N. rustica* and the tubes enter the sac more slowly than *N. rustica* pollen tubes. One of the sperm-nuclei fuses with a polar nucleus and albumen is formed in 90% of cases. Fertilization of the egg cell has not been observed but in 2 cases degenerated embryos have been found, surrounded by albumen cells. In other cases nucellar embryos were observed. The fruits never contained normal seeds.—*A. Biraghi.*

11196. BONVICINI, M. Spiga ramificata in un grano tenero (Triticum vulgare Host). [Branched spike of wheat.] *Italia Agric.* 68(3): (1-7). 4 fig. 1930.—There is described a spike of *Triticum vulgare* which had two spikelets transformed into true spikes, with complete spikelets replacing the individual florets.—*M. Bonvicini (transl. by H. S. Wolfe).*

11197. CHAUDHURI, H., and A. R. AKHTAR. The coral-roots of Cycas revoluta, Cycas circinalis and Zamia floridana and the algae inhabiting them. *Jour. Indian Bot. Soc.* 10(1): 43-59. 4 pl. 1931.—Material was obtained from cultivated plants at Lahore. Coral roots are dichotomously branched, and are formed from the ends of rootlets, or sometimes from the sides of roots. The coral branch system is rather compact in *C. circinalis*, less so in *C. revoluta*, and is loose in *Zamia*. Larger cells containing bacteria occur scattered through the cortex and stele. They are abundant in roots of *C. revoluta* which do not form coral, and which appear to be normal. The alga, *Anabaena cycoideae* [*cycadeae* ?], is restricted to a cylinder 2 cells thick about the middle of the cortex. The cylinder does not extend into the root tip, and is interrupted beneath the rather numerous lenticels. Pure cultures of the alga were obtained. Best growth took place in diffuse light and moderate temp. Cultures showed little growth when exposed to direct sunlight, and some were decolorized in the hot season (Apr. and May). Cultures in flasks buried at various depths in the soil gave maximum growth at 15-20 cm. depth. Cultures made from soil at various depths in the vicinity of *Cycas* plants showed that *Anabaena* does not occur below 25 cm. In cultures, heterocysts were more abundant than in coral roots, and "the cells were found to form spores." Infection of roots apparently is through the lenticels by means either of spores or filaments. "Young rootlets and root hairs never showed the presence of the alga, and root tips dipping into a culture of *Anabaena* failed to get infected." Corals formed by bacteria and by *Anabaena* are different, and the former cannot be regarded as a first stage in the formation of the latter. Only alga corals are negatively geotropic, and come out of the soil. If not actually beneficial to the roots, the alga certainly is not harmful.—*W. Dudgeon.*

11198. CHAUDHURI, H., and A. R. AKHTAR. A study of the root-tubercles of Podocarpus chinensis. *Jour. Indian Bot. Soc.* 10(2): 92-99. 2 pl. 1931.—Tubercles from cultivated trees at Lahore were 500-675 μ in diam., contained a vascular cylinder extending to about the middle, and were surrounded by 3-4 layers of cortical tissue of the parent root. Tubercles were sterilized externally, crushed, and cultured. 3 spp. of fungi were isolated: *Fusarium* sp., *Aspergillus* sp., and 1 undetermined. The hyphae of the last resembled those observed in the bark and cortex of the roots, and in the tissues of the tubercles. No *Podocarpus* free from fungi could be found for inoculation experiments. Inoculation of *Cycas* and *Casuarina* roots was successful, but tubercles were not produced. The undetermined fungus showed N fixation when cultured in Beijerinck's solution.—*W. Dudgeon.*

11199. EMBERGER, LOUIS, (préface de R. MAIRE). Éléments de morphologie florale. 102p. 45 fig. Le François: Paris, 1931.—The well known facts of the external morphology, relations to reproduction, and importance in plant classification are treated in a fashion of interest to the elementary student of plant morphology.

11200. EXBRAYAT-DURIVAUX, CHARLES. Notes sur la germination des Moringa malgaches. *Ann. Mus. Colonial Marseille* 8(2): 5-21. 3 fig. 1930.—*Moringa hildebrandtii* and *M. drouhardi* of Madagascar both bear their cotyledons above the soil while those of *M. pterygosperma* and *M. aptera* are buried. On *M. hildebrandtii* they are well elevated while on *M. drouhardi* they remain quite near the soil surface. Both exhibit tuberization during the germination period while *M. pterygosperma* and *M. aptera* do not. The hypocotyl region only is affected in tuberization, and this region is not developed in the latter species which have subterranean cotyledons. The entire length of the hypocotyl of *M. drouhardi* shows tuberization while *M. hildebrandtii* exhibits it only on the lower part. The main root participates but little in this tuberization and only in the immediate region of the union with the stem. The lower part of the epicotyl of *M. drouhardi* shows a slight thickening which is not observed in *M. hildebrandtii*. Tuberization is due essentially to development of secondary xylem and phloem tissues which remain thin-walled and which become packed with starch grains. No medullary gum canals were observed in seedlings of these 2 Madagascar spp. when grown in the greenhouse.—*L. E. Miles.*

11201. FARR, WANDA K. Cotton fibers. I. Origin and early stages of elongation. *Contr. Boyce Thompson Inst.* 3(3): 441-458. 4 fig. 1931.—Early stages of elongation of fibers from the seed coat of *Gossypium hirsutum* in mounts of fresh material show wide variation in fiber length. The appearance of the cytoplasm indicated that growth initiation had taken place more recently in the shorter than in the longer fibers. The 32-fold increase in surface area of the seed during the first 20 days from the date of flowering, in comparison with 2-fold increase in length of transverse axes of epidermal cells during the same period, shows that cell enlargement is not alone responsible for the tangential extension of the epidermal layer of the seed coat. Many dividing cells in the epidermal layer from the date of

flowering to the 12th day following reveal the chief method of extension of the epidermal covering. Early stages of fiber elongation from epidermal cells which were apparently daughter cells of recent divisions furnish evidence that fibers may originate from cells which are not yet formed upon the date of flowering. Median sections of bases of fibers in all stages of development show neither extreme attenuation nor extreme constriction. Bolls in all stages of development failed to reveal the presence of any liquid or semi-liquid substance in the boll cavity. The nutrition of the fiber in any other fashion than through its basal connection with the seed is unlikely.—*W. K. Farr.*

11202. **FIGDOR, WILHELM. Über tütenförmige Blätter und die ungeschlechtliche Vermehrung von Bryophyllum proliferum Bowie.** *Akad. Wiss. Wien Math.-Naturw. Kl. I. Abt.* 137(10): 817-824. 4 fig. 1929.—Correction is made of "*B. calycinum* Salisb." of previous article to *B. proliferum* Bowie. Ascidia were formed usually from terminal leaflets. The cause is not clear; in many cases lice were present, and claims for artificially produced ascidia can be made only when experimental plants are kept free from plant and animal injury. Asexual reproduction by adventitious buds which occur on ascidia is discussed.—*L. M. Snow.*

11203. **FRANCIS, W. D. The anatomy of the Australian bush nut (Macadamia ternifolia).** *Proc. Roy. Soc. Queensland* 39: 43-53. 1 pl., 10 fig. 1927(1928).—A description of the external and internal anatomy, embryo, and qualitative composition of the nut of *Macadamia ternifolia* and comparison of the seed with related species.

11204. **GUARD, ARTHUR T. Development of floral organs of the soy bean.** *Bot. Gaz.* 91(1): 97-102. 16 fig. 1931.—The mature flower of *Soja max* consists of a calyx tube with 5 unequal lobes, 5 distinct petals, 10 stamens (9 united and 1 free), and 1 carpel. Both unicellular and multicellular trichomes are found on the calyx and pistil. The flower primordium appears first as a protuberance in the axil of a bract. The order of emergence of the floral organs is sepals, petals, outer cycle of stamens, inner cycle of stamens, pistil. The order of emergence within each cycle is from the anterior to the posterior side of the receptacle. Development of the petals is slow at first, but later becomes rapid. The stamens are free at first; later 9 become united leaving 1 of the inner cycle free. The 1-4 campylotropous ovules develop simultaneously, and the micropylar end is directed toward the distal end of the ovary.—*Author's summary.*

11205. **HAYATA, B. On the systematic anatomy of the genus Sasa Mk. et Shib.** [In Japanese.] *Bot. Mag. [Tokyo]* 43(505): 23-44. 1929.

11206. **HAYATA, B. A new theory on the construction of polycyclic steles.** [In Japanese.] *Bot. Mag. [Tokyo]* 43(511): 340-354. 52 fig. 1929.—According to the prevalent theory polycyclic steles, though seeming generally to possess very complicated structure, are in the case of dictyosteles composed of several meristeles arranged on several imaginary concentric cylinders. Consequently, when observed in section, the meristeles are considered to be disposed on certain concentric imaginary rings which correspond to the sections of the cylinders just mentioned. The author, by observing the so-called polycyclic stele, isolated by a special method from the rhizome of *Angiopteris evecta*, inclines to a very different interpretation. He has found that the same stele should be interpreted as composed of many imaginary conical wedges surrounded by meristeles. These wedges are inserted between each two ridges of an imaginary spiral. The stele is not regarded as consisting of several concentric cylinders, as the word "polycyclic" indicates. The reason for considering a wedge as an element composing the stele is that the rhizomes generally possess the form of a cone of which the apical portion alone exists, the remaining being weathered out. If they are, on the other hand, columnar in shape, one would expect a small cylinder in place of a wedge. According to the author's wedge theory, in the section of a rhizome there exists a certain number of the smaller sections of the imaginary wedges disposed on the fundamental spiral, resembling an Archimedian or a logarithmic spiral, as the case may be, each of the wedges bearing to one another the same mathematical relation as in phyllotaxis. The meristeles seen in the section of the rhizome are so arranged as to make several sets, each belonging to one of the smaller sections of the imaginary wedges, and the meristeles of each set are disposed on each smaller ring which answers to the smaller section of the wedges; these rings exactly correspond to leaf-gaps of the stele. To test the wedge theory the author has tried to interpret by it the figures of the so-called polycyclic steles appearing in the literature, such as those given by Shove, West, Kuhn and Bower on the steles of *Angiopteris, Danaea, Kaulfussia, Thysopteris* and *Saccoloma,* and has found that not only may all such figures be easily elucidated by the new theory, but also a very clear mathematical significance may be given in respect to their otherwise quite disorderly arrangement of meristeles.—*Author (courtesy Japanese Jour. Bot.).*

11207. **KANAMARU, KISOU. Studies on the mechanism of dyeing of cellulose. I. On the dyeing of cellulose with basic dyes (preliminary paper). Some known facts which are consistent with the electrical adsorption theory of dyeing.** *Cellulose Indust.* 7(7): 42. 1931.—Abstract.

11208. **KASHYAP, SHIV RAM. Some peculiar cones and microsporophylls of Cycas circinalis.** *Jour. Indian Bot. Soc.* 9(4): 187-189. 4 pl. 1930.—All staminate cones examined have small scales at the base which sometimes pass over gradually into the sporophylls; but usually between the scales and the sporophylls there is a naked stalk with occasionally 2 or 3 scattered scales. Cultivated plants at Lahore have produced cones with larger groups of scales at the base, the uppermost bearing sporangia. A few cones had the basal area as large as the upper normal portion, so that they seemed to consist of two equal parts separated by a naked stalk. The alternate tracts of scales and sporophylls in the staminate cones are regarded as homologous with the similarly alternating tracts of scale leaves and foliage leaves on the vegetative stems. Under certain conditions the area of scales at the base of the cones may become greatly enlarged, and the upper scales then bear sporangia and behave like sporophylls. A few staminate sporophylls, always from the base of the distal or true cone area, were more or less deeply divided into two equal lobes, and often their tips were again once or twice dichotomized. This dichotomy is regarded as a reversion to a very ancient ancestral condition.—*W. Dudgeon.*

11209. **KASHYAP, SHIV RAM. Some abnormal cones in Equisetum debile.** *Jour. Indian Bot. Soc.* 9(4): 240-241. 1 pl. 1930.—Three shoots found at Lahore each bore 2 cones, one above the other, with 1 or 2 whorls of leaves intervening. In one lower cone the upper whorl was transitional between leaf and sporophyll; and in one upper cone some of the lobes of the annulus bore sporangia, and the leaf whorl below it was somewhat like an annulus. This seems to confirm the idea that the annulus and the sporangiophore whorls are homologous with ordinary leaf whorls.—*W. Dudgeon.*

11210. **KISSER, JOSEF. Methodik der Herstellung pflanzlicher Aschenbilder und Kieselskelette sowie von Anthrakogrammen.** In: **EMIL ABDERHALDEN. Handbuch der biologischen Arbeitsmethoden.** Abt. XI. **Chemische, physikalische und physikalisch-chemische Methoden zur Untersuchung des Bodens und der Pflanze.** Teil 4, Heft 2, Lief. 353. p. 193-236. 1 pl., 2 fig. Urban & Schwarzenberg: Berlin, 1931.—A thin section of plant tissue carefully heated to destroy organic matter leaves the ash in its original position and sometimes unaltered. Such an outline of the plant ash constituents is called a spodogram. If the heating is continued only

long enough to carbonize the tissue, the resulting object is called an anthracogram. The distribution of minerals can be presented with a fair degree of accuracy in single cells as well as the general distribution of minerals in plant tissues. E.g., in *Spirogyra*, after incineration, there is very little ash in the region of the central sap, the cell wall contains more, while most of the ash is present in a spiral arrangement like that of the original chloroplast. In the nucleus of pollen grains of *Vicia faba*, the minerals are mostly contained in the chromosomes. Silica alone is unaltered by incineration. Calcium salts, usually present as the oxalate, are changed to the carbonate without altering the form of the original crystals. All kinds of plant materials can be used—either fresh or dried. Thick leaves must be sectioned, 20-30 μ gives best results. Wood contains few crystals and may be sectioned thicker. Bark and cortex are usually full of crystals and should be cut as thin as possible. The epidermis, usually silicified, is best used alone. In tissues containing alkaline salts with silica, heating causes the silica to melt and change its form. Alkalies may be removed by preliminary treatment with mineral acids, followed by washing in water. For incineration, plant sections on a slide are placed in a quartz tube externally heated by a coil of resistance wire; a rheostat in the circuit controls the temp. The material is heated gently until carbonized, then to a dull red heat for ½-1½ hrs. Sections may also be heated on a sheet of platinum over a bunsen burner; in this case the ash must be transferred without alteration to a slide coated with celloidin. The sticky celloidin takes up the crystals, which sink into the celloidin if the slide is held inverted over a vapor of alcohol-ether. On drying, the thin sheet of celloidin with the crystals embedded may be removed from the slide with a razor blade, and mounted in balsam or a water medium. Thin sections of coal may be incinerated in the same way to produce skeleton pictures of the ash constituents. During the carbonization of plant sections protected with a coverglass, the color of the tissue changes from yellow to red, brown, and finally black. By heating only to the red-brown stage, the material is in the best condition for photomicrographs.—*W. H. Emig.*

11213. PFEIFFER, NORMA E. A morphological study of Gladiolus. *Contr. Boyce Thompson Inst.* 3(2) : 173-196. 3 pl., 7 fig. 1931.—The life history of *Gladiolus*, studied with chief reference to Halley and Alice Tiplady corms treated in the fall, showed development in the varieties to be similar except for differences in time relations. Mitotic divisions were numerous in 12-18 days after treatment, when there was external evidence of growth. The structure of the leaf and contractile root and the development of the stem with the production of a terminal flower spike are described. In the flower the order in ontogeny is stamen, perianth, and carpel sets. The development of microsporangia and ovules with their respective spores is characteristic for monocotyledons as is the embryo sac except for conspicuous synergid beaks. The fertilized egg produces an embryo at first massive, later elongating, which is surrounded by endosperm cells with thick hemicellulose walls. Data are given for the time required by the main varieties for the different stages described.—*N. E. Pfeiffer.*

11214. SINHA, B. N. On a peculiar abnormality of capitula in Tagetes erecta L. *Jour. Indian Bot. Soc.* 9(4) : 244-247. 2 pl., 1 fig. 1930.—Stalks bearing small heads were found growing from ordinary heads. In some instances the small heads again produce a few little stalks and miniature heads. Some of the stalks were fasciated.—*W. Dudgeon.*

11215. WOODROOF, J. G., and NAOMI C. WOODROOF. Abnormalities in pecans. I. Abnormalities in pecan flowers. II. Abnormalities in pecan nuts. [By] **J. G. WOODROOF.** *Jour. Heredity* 21(1) : 39-44. 5 fig.; (2) : 91-96. 5 fig. 1930.—I. Studies of the normal development of staminate and pistillate flowers of *Hickoria pecan* revealed 4 types of abnormal arrangement and structure: (a) "perfect-flower-clusters," found on the Beveridge variety for 5 successive years; (b) a second type of "perfect-flower-cluster," found on vigorous shoots of the Jerome variety; (c) an excessive number of catkins in certain groups on the Jerome and Indiana varieties; (d) less than the normal number of catkins in groups on several varieties. None of these abnormalities is considered of economic importance, but they suggest that the flowering habit is genetically unstable. —II. Three types of nut abnormalities are pointed out: (a) variations in number of cotyledons of certain varieties, (b) variations in number of divisions of the shell or endocarp, (c) twinning in which the seed, endocarp and exocarp are abnormal in shape. Variations in the number of segments of the exocarp and in the number of nuts per cluster are considered differences of degree rather than of kind and so not abnormal.—*J. G. Woodroof.*

Mat. e Nat.* 13(6) : 439-442. 1 fig.; (7) : 532-535. 3 fig. 1931.—Descriptive and taxonomic notes are given on *Lithophyllum fortunatum; Mesophyllum* **navarroi*** (p. 440); *Porolithon* **inaspectum*** (p. 532); and *Melobesia* (*Lithoporella*) *melobesioides** from the Miocene. A similarity between these Miocene terrains and those of the Mediterranean countries is noted.

11217. BANDULSKA, HELENA. On the cuticles of some recent and fossil Myrtaceae. *Jour. Linn. Soc. London, Bot.* 48(325) : 657-671. 2 pl., 24 fig. 1931.—General form and anatomical characters of the leaf are discussed, with minute attention to epidermis, in *Rhodomyrtus* and *Tristania*. *R.* **sinuata** (*Dicotylophyllum sinuatum* Bandulska) (p. 659); *Tristania* **bournensis*** (p. 666), Bournemouth Eocene Beds, England; *T.* **toscana*** (p. 668), Eogene, Italy, type in Brit. Mus. There is a strong family resemblance between the cuticles of *Rhodomyrtus* and *Tristania*, but the latter more frequently has isodiametric stomata and a larger number of narrow and very distinctive girdling cells encircling the guard-cells. There is, moreover, relatively less parenchyma and there are more stomata per unit of area in *Tristania* than in *Rhodomyrtus*.

11218. CARPENTIER, ALFRED. Empreintes de fructification trouvées en 1929 dans le Westphalien du nord de la France. *Rev. Gén. Bot.* 41(488) : 469-473. 1 pl., 2 fig. 1929.—Microsporophylls attributed to *Neuropteris gigantea* bear microsporangia arranged in small groups or sori, not united into synangia, and recalling

the genus *Plinthiotheca* Zeiller. Certain seeds enclosed in cupules, referable to *Lagenostoma kidstoni* Arber, are closely associated with *Sphenopteris striata* (Gothan). The sori of *Corynepteris sternbergi* (Ett.) are composed of 5 or 6 sporangia, united at first, but separating from their tips downwards at maturity.—*W. N. Edwards.*

11219. CARPENTIER, ALFRED. Observations sur quelques empreintes du Westphalien du Nord de la France. *Rev. Gén. Bot.* [*Paris*] 42(499) : 385-390. 1 pl. 1930.—Seeds resembling *Trigonocarpus* were found in association with *Alethopteris serli.* These are large (65 mm. long) and with long micropylar beaks. They resemble those assigned by Kidston to *Neuropteris heterophylla.* Fronds resembling those of *Sphenopteris* were found in which the terminal branches bear specialized pinnules with sporangia resembling those of *Rhodea.*—*C. A. Arnold.*

11220. CARPENTIER, ALFRED. Observations sur deux types d'inflorescences trouvés dans les schistes permiens du Bou Achouch. (Maroc Central). *Bull. Soc. Geol. France* 30(3/4) : 191-194. 2 pl. 1930.—Two inflorescences from the Permian schist of central Morocco are described: (1) Male inflorescences, identical with those described by Goeppert in 1864 from the Permian of Bohemia and Silesia under the name *Dictyothalamus schrollianus**, the microsporophylls of which show characters similar to those of the genus *Potoniea* Zeiller; (2) a ♂ disc furrowed with radial grooves with sinuous borders, apparently related to the "androphylls" which Renault attributed to his *Dolerophyllum berthieri.*—*W. Berry.*

11221. CROOKALL, R. Petrified plants from the Pennant rock. *Summary Progr. Geol. Surv. Gr. Brit. and Mus. Pract. Geol.* 1930(2) : 52-59. 1 pl. 1931.—The presence of numerous petrified plant-remains in the Pennant Rock of the S. Wales and the Bristol and Somerset coalfields is noted. The horizon (Staffordian Series) is of considerable importance as lying about midway between the older British (Lanarkian) and the younger French (Permo-Carboniferous) plant-beds. An example of a medullosan petiole (*Sutcliffia*) has already been described, and specimens of *Psaronius*, Mesoxylon*, Dadoxylon** and *Calamites** are here dealt with. The flora is thus shown to include members of the Filicales, Equisetales, Pteridospermeae and Cordaitales.—*Author's summary.*

11222. DAVIES, DAVID. Correlation and palaeontology of the coal measures in east Glamorganshire. *Phil. Trans. Roy. Soc. London* B 217(442) : 91-153. Map. 7 pl. 1929.—An ecological study of Welsh Westphalian, Staffordian, and Radstockian floras based on percentage analyses, with numerous charts and tables, of 390,000 specimens collected from 29 successive horizons. Physical conditions, due to elevation and depression of land surfaces, determined the distribution and relative proportions of various groups of plants. Dominance of Filicales and Pteridosperms indicates a dry flora and an episode of elevated land surface; Lycopodiales indicate a swampy episode (wet flora). The former is accompanied by greater variety of species of the different classes of plants, and depression of land surface is followed by a decrease in the number of species. Intermediate floras are dominated by Equisetales and Cordaitales, which perhaps grew at a height of 20-100 ft. above sea level. On horizons where Lycopodiales are dominant, shell bands generally occur, suggesting a deltaic or brackish water rather than a marine habitat. The wet flora probably developed at a height of 0-20 ft., and the dry flora at 100-300 ft. Five dry episodes (4 in the Westphalian) alternated with 4 wet episodes (3 in the Westphalian). Half the horizons examined show dominance of intermediate flora, and only 13% dominance of wet flora. No portions of drifted plants are found in the underclay, though they may occur in shales overlying the seams, and this is held to confirm the growth *in situ* theory, with the corollary that each seam must have been submerged after its formation, prior to the formation of a subsequent seam. Split seams indicate local subsidence. In the Westphalian the Equisetales are dominant over other classes of plants; in the Staffordian and Radstockian the Filicales and Pteridosperms are dominant. Of the fern-like plants *Neuropteris* is the most abundant throughout; *Mariopteris, Pecopteris, Sphenopteris,* and *Alethopteris* may be either well represented or absent altogether. Seeds of *Trigonocarpus* are always associated with *Alethopteris,* but no single instance of connexion has been observed. *Cordaites* is associated with *Samaropsis. Sphenophyllum* is found mainly with the fern-like plants, and was therefore probably a dry-flora climber. Three new species are mentioned but not described (*Mariopteris daviesi* Kidston, *Samaropsis cambrica* Kidston, and *Stigmaria* sp.); 18 species are new to Britain. Other fossils tabulated with their respective horizons include annelids, arachnids, insects, mollusks and a few fish scales.—*W. N. Edwards.*

Untersuchung des Bodens und der Pflanze. Teil 4, Heft 2. Ernährung und Stoffwechsel der Pflanzen, Lief. 353.] P. 331-353. 2 fig. Urban & Schwarzenberg: Berlin, 1931.

11230. **KISSER, J. G.** The preparation of anthracograms from thin sections of fossil plants. *Jour. Indian Bot. Soc.* 10(1): 60-62. 1 pl. 1931.—Thin sections of petrified plant material in which there is insufficient color to differentiate cell walls and other details may be much improved by passing them through alcohol and benzol, and boiling them in liquid paraffin under a large cover glass for 1 min. or more. Traces of organic matter in the cell walls are carbonized, and appear first yellowish, then reddish-brown, and finally blackish. When the desired degree of carbonization is reached, the slide is cooled, the paraffin is dissolved out, and the section is mounted in the usual way.—*W. Dudgeon.*

11231. **KUBART, BRUNO.** Einige Bemerkungen zur Frage des Nachweises der Lauraceen-Gattung Umbellularia in den tertiären "Redwood"-Beständen Nordamerikas. [The genus Umbellularia of the family Lauracea in the Tertiary period of redwood forests in North America.] *Biol. Generalis* [*Vienna*] 3(5/8): 585-594. 3 fig. 1927.

11232. **[LEPCHENKO, Ya.]** ЛЕПЧЕНКО, Я. Про копалинні рослини на долішньо-третинних пісковиках Волині. Попередній звіт с дослідів 1927-1928 p. p. (On the fossil plants in the Lower Tertiary sandstones of Volhynia. A preliminary report of investigations in the years 1927-1928.) [English summary.] Труди Українського Науково-дослідчого Геологічного Інституту (*Abhandl. Ukrain. Wiss.-Forsch. Geol. Inst.*) 3: 159-185. 8 pl. 1929.—The author reviews the literature and appends a list and figures of 20 spp. from his own collections.

11233. **MATTIROLO, O.** La Juglans bergomensis Bals. Crib. testè ritrovata in Piemonte. [Juglans bergomensis B. Cribelli recently discovered in Piedmont.] In: *Mem. Ist. Geol. R. Univ. Padova* 8: 1-7. (separately paged) 1 fig. 1930.

11234. **MAURY, CARLOTTA J.** Correlation of Antillean fossil floras. *Science* 72(1862): 253-254. 1930.—In Porto Rico south of Cidra rocks containing *Nilssonia* have been referred to Lr. Cretaceous because of corals in the rocks above the *Nilssonia*. Due to foraminiferal evidence the rocks suggest Up. Cretaceous age. In Porto Rico and other of the islands *Archaeolithothamnium* shows affinity to species of the genus found in the Oligocene and in Up. Cretaceous. Palms and dicotyledons abundant in the Rio Collazo of Porto Rico, have been referred to Oligocene. In Trinidad the flora has been described as of Miocene age. In Dominican Republic certain fossils have been referred to Middle Miocene while certain younger fossils have been referred to Miocene or to Pliocene. In Porto Rico a post Pliocene walnut has been found. The fossils indicate that the climate of the West Indies has remained unchanged from Oligocene to the present time. A fossil manatee from Oligocene time has been found in southern Porto Rico.—*B. McAvoy.*

11235. **[PERSIDS'KIĬ, D. Ya.]** ПЕРСИДСЬКИЙ, Д. Я. Про відбитки рослин на третинних пісковиках Аджамки. (Some plants of Tertiary sandstone near Adjamka, western Ukraine.) [English summary.] Вісник Українського Відділу Геологичного Комітету (*Bull. Sect. Ucraine, Com. Géol.*) 13. 125-128. 1 pl. 1929.—*Dryophyllum furcinerve*, Quercus paleovirens**, and *Cinnamomum subrotundum** are described, the last 2 recorded from this formation for the first time. The sandstone is correlated with the Kharkov layer.

11236. **[PIMENOVA, N.]** ПИМЕНОВА, Н. Матеріяли до третинної фльори Коростенщини. [Tertiary flora of the Korosten' region.] [English summary.] Труди Українського Науково-дослідчого Геологічного Інституту (*Abhandl. Ukrain. Wiss.-Forsch. Geol. Inst.*) 3: 186-188. 1 fig. 1929.—The author gives a preliminary list of fossil plants from 9 localities.

11237. **[PIMENOVA, N.]** ПИМЕНОВА, Н. Відбитки рослин з пісковиків Зінов'ївської округи. [Fossil plants in the sandstones of Zinovievsk district.] [English summary.] Труди Українського Науково-дослідчого Геологічного Інституту (*Abhandl. Ukrain. Wiss.-Forsch. Geol. Inst.*) 3: 189-195. 3 pl. 1929.—Four spp. are added to the 3 previously known from the village Adjamka, and 12 spp. reported from Arsenivka, 100 km. distant. All are figured. The enclosing strata are tentatively assigned to the Lower Oligocene.

11238. **PULT, ANTONIO.** Lignina e carbogenesi. [Lignin and coal formation.] *Atti Congr. Naz. Chim. Pura ed Appl.* 3: 529-532. 1929(1930).—From the chemical nature of the substances concerned it is concluded that while the solid products of the decay of wood come from lignin and make up the characteristic part of coal, i.e., the part not soluble in ordinary solvents, the volatile parts of coal come from cellulose. But research shows that a small part of the cellulose, however, is carbonized into solid portions, while a small part of the lignin is volatilized and is soluble in ordinary solvents.—*From author's conclusions* (*transl.*).

11239. **RAINERI, RITA.** Dasycladaceae nel "Liburnico" del Colle di Medea (Friuli). In: *Mem. Ist. Geol. R. Univ. Padova* 8: 1-11. (separately paged) 3 fig. 1930.—Descriptions of *Cympolia* paronai* (p. 4), *C. elongata**, and *Neomeris* sp.

11240. **REID, ELEANOR M.** Tertiary fruits and seeds from Saint Tudy (Finistère). Collected by the late M. Henri du Laurens de la Barre. *Bull. Soc. Géol. et Minér. Bretagne* 8(1/4): 36-65. 3 pl., 1 fig. 1927 (1928).—This study of very refractory materials results in the conclusion that the flora shows certain Malayan characters, is probably Eocene in age, and indicates a sandy bush delta assemblage. The new forms, several of which represent genera not hitherto found fossil, are: *Limnocarpus* sp.* (p. 41), *Corypha* minima* (p. 43), *Ilex* multicostata* (p. 44), *Nyssa* oviformis* (p. 45), *Rhodomyrtus* sp.* (p. 48), *Aralia* laevis* (p. 49), *Dendropanax* gallicum* (p. 50), *Dulaurensia* pulchra* (p. 52), *Prismatomeris* corisopitensis* (p. 55). Eight kinds of *Carpolithus* of unknown affinities, a leaf fragment and 2 other unknown objects not certainly of a vegetable nature are mentioned.—*E. W. Berry.*

11241. **ROSENDAHL, FRITZ.** Die Entstehung der Kohle im Lichte der chemischen und biologischen Forschung. *Naturwissenschaften* 19(13): 281-289. 1931.—The origin and processes of coal formation from plant remains and the geological and biological interrelationships are accepted facts. Based on results of chemical research, it is concluded that lignin and not cellulose is the basic substance in coal formation. Biological research shows that peat formed from woody material broken down by bacteria, is the first stage in coal formation, likewise that subsequent changes are also wrought by bacteria. Taylor's theory that the building of peat into brown or hard coal depends to a great extent upon the nature of the strata overlying the peat, is cited.—*F. Rosendahl* (*transl. by B. McAvoy.*)

PALEOZOOLOGY

Handel, Sjöfart, etc.)* [*Oslo*] No. 26. 1-66. 5 maps, (col.) 3 pl., 6 fig. 1929.—Records from the Triassic of Spitzbergen the brachiopods *Spirifer* sp. and *Terebratula* sp., the pelecypods *Posidonomya mimer, Posidonia tenuissima*, Myalina, Anodontophora wittenburgi*, Daonella dubia, D.* cf. *lindstromi, Lima biarata, Gervilleia löwenighi, Macrodon, Pseudomonotis clarai, P. ochotica* var. *densistriata,* some gastropods, and the cephalopods, *Flemingites* sp.?*, *Meekoceras* sp.?*, *Keyserlingites* cf. *subrobustus*, Ammonites* sp.?*, *Hollandites* sp.?*, *H.* cf. *organi*, H.* aff. *montis bovis, Ceratites trinodosus, C. laqueatus, C. nathorsti, C. humboldtiensis, C.* sp.?, *Protrachyceras americanum, Nevadites whitneyi, Ptychites euglyphus, P. lundgreni, P. nordenskiöldi, P. trochleaeformis P. latifrons, Nathostites lenticularis*, N. lindströmi*, Parapopanoceras verneuili, Eutomoceras* aff. *laubei*, Arctoceras,* and *Ophiceras?**.—*D. J. MacNeil.*

11246. **GETZENDANER, F. M. Geologic section of Rio Grande embayment, Texas, and implied history.** *Bull. Amer. Assoc. Petrol. Geol.* 14(11): 1425-1437. Map. 1930.—Records from this Mesozoic-Cenozoic locality some fruits of the stonewort *Chara;* the Foraminifera *Orbitulina texana* and *Nodosaria texana;* the pelecypods *Exogyra texana, E. ponderosa, E. costata, Inoceramus, Ostrea tasex,* and *Unio;* poorly preserved gastropods; the cephalopod *Sphenodiscus lenticularis;* and a few ostracods.—*D. J. MacNeil.*

11247. **GILES, ALBERT W. Pennsylvanian climates and paleontology.** *Bull. Amer. Assoc. Petrol. Geol.* 14(10): 1279-1299. Map. 1930.—Reviews the biological reasons for assigning tropical or sub-tropical conditions to the Pennsylvanian. Maintains that adaptations during the time subsequent to the Pennsylvanian can account for the characters preserved in organisms from that period, without the assumption of a warm climate. Discusses the rapid development of the insects during the period, referring to the dragon-fly, *Meganeura moneyi.* This and allied insects were the ancestors of the present day Blattoidea, Odonata, Orthoptera, and related forms, representing about 12 orders. Contends that their development was not dependent on climate, this factor not being significant in the rapid specialization of the Tertiary titanotheres, zeuglodon whales, and amblypods, nor in the Mesozoic reptiles, and the birds of the early Tertiary. Lists as the important Paleozoic reef builders, Stromatoporoidea, Tabulata, and Tetracoralla; while those of today, living as far as 71 N. latitude, are, *Lophohelia, Amphihelia* and *Dendrophyllia.* Contends that the amphibians of the orders, Salientia, Lysorophia, Lepospondyli, Temnospondyli and Stereospondyli, show remarkable changes in size and differentiation during the Pennsylvanian, before the close of the period certain groups having evolved into the primitive orders of reptiles, Protorosauria, Cotylosauria and Theromorpha. Refers to the first appearance of spiders, land snails, and fresh-water gastropods during the Pennsylvanian, and to the decrease in number of the corals and crinoids, and the rarity of cystoids, asteroids, echinoids, eurypterids, and trilobites, while among the mollusks there was a decrease in nautilids and an increase in complexity of suture among the ammonoids. Interprets certain plant characteristics of the Pennsylvanian as meaning that the climate was temperate, referring especially to the structure of *Calamites, Lepidodendron,* and *Sigillaria.*—*D. J. MacNeil.*

11248. **GILES, ALBERT W., and EUGENE B. BREWSTER. Hale Mountain section in northwest Arkansas.** *Bull. Amer. Assoc. Petrol. Geol.* 14(2): 121-138. 2 fig. 1930.—Records from this Mississippian formation the echinoderm *Pentremites* and the bryozoan *Archimedes.*—*D. J. MacNeil.*

11249. **GOULD, CHAS. N. Fossil bones and artifacts at Frederick.** *Bull. Univ. Oklahoma (Proc. Oklahoma Acad. Sci.)* 9(456): 90-92. 1929.—Human artifacts have been found in gravels in asociation with extinct, presumably Pleistocene, mammal bones. The artifacts are believed to be of Aftonian (Pleistocene) age.—*B. F. Howell.*

11250. **GREPPIN, ED., und AUG. TOBLER. Zur Geologie und Paläontologie des Flexurgebietes von Stetten-Lörrach.** *Verhandl. Naturforsch. Ges. Basel* 40(2): 536-587. 1 pl., 6 fig. 1928-29(1929).—A study of the stratigraphy and structure of the region between the towns of Stetten and Lörrach, near Basel, Switzerland, where faulted Triassic, Jurassic, and Tertiary strata are

exposed. Detailed descriptions of the outcrops are given, together with fossil lists, including the following new Bajocian spp. (not described): (Pelecypoda) *Trigonia badensis;* (Gastropoda) *Pleurotomaria alemanica;* (Cephalopoda) *P. badensis, Belemnites subrhenanus.*—*J. R. Sandidge.*

11251. HENNY, GERARD. McLure shale of the Coalinga region, Fresno and Kings counties, California. *Bull. Amer. Petrol. Geol.* 14(4): 403-410. Map, 2 fig. 1930.—Records from the Miocene of this region an echinoderm *Astrodapsis* sp., with prominent raised petals; the pelecypods *Pecten estrellanus, P.* cf. *crassicardo bifurmatis, P. raymondi, Chione semiplicata, Solen perrini,* and *Phacoides annulata;* the gastropods *Thais carisaensis, T. kettlemanensis,* and *Calyptrea* cf. *martini;* and the crustacean *Tamiosoma gregaria.*—*D. J. MacNeil.*

11252. [KASSIN, N. G.] КАССИН, Н. Г. Общая геологическая карта Европейской части С. С. С. Р. Лист 107-й. Вятка-Слободской-Омутнинск-Кай. [General geological map of the European part of U. S. S. R. Sheet 107. Viatka-Slobodskoĭ-Omutninsk-Kaĭ.] [French résumé.] Труды Геологического Комитета; Ленинград (*Mém. Com. Géol. Nouv. Sér., Leningrad*) 158 (pt. 1). 1-268. Map. 1928.—Records from the Permian and Triassic of this region the pelecypods *Palaeomutela krotowi, P. inostranzevi, Oligodon latus, Nayadites* sp., and *N. verneuili;* the fishes *Palaeoniscus tuberculatus, P. costatus, Acrolepis rhombifera, Platysomus biarmicus,* and *Amblypterus* cf. *orientalis;* reptilian bones, including *Melosaurus uralensis;* and the skull of a *Rhinesuchus volgo-dwinensis;* and also the plant *Phyllotheca* sp. From the Jurassic the brachiopod *Terebratula* sp.; pelecypods *Inoceramus retrosus, Avicula* sp., *Gryphaea,* and many spp. of *Aucella;* the cephalopods, *Perisphinctes* sp., *P. panderi,* and *Virgatites* cf. *scythicus,* and many *Belemnites;* and the reptile *Ichthyosaurus trigonus.* From the Cretaceous many pelecypods of the genus *Aucella,* and the cephalopods *Polyptychites* cf. *anabarensis, P. keyserlingi,* and *Belemnites subquadratus.*—*D. J. MacNeil.*

11253. KELLUM, LEWIS BURNETT. Similarity of surface geology in front range of Sierra Madre oriental to subsurface in Mexican South fields. *Bull. Amer. Assoc. Petrol. Geol.* 14(1): 73-91. 3 fig. 1930.—States that Foraminifera are plentiful in the Upper Cretaceous of this region, and records the pelecypod, *Inoceramus.* From the Middle Cretaceous is recorded the foraminiferan, *Miliolina* and the pelecypod, *Kingena wacoensis.* Remarks that there are also some gastropods in the fauna of this formation.—*D. J. MacNeil.*

11254. McCLENNAN, HUGH W. Subsurface distribution of Pre-Mississippian rocks of Kansas and Oklahoma. *Bull. Amer. Assoc. Petrol. Geol.* 14(12): 2 maps, 1 fig. 1535-1556. 1930.—Records from the Pre-Mississippian formations of Kansas the bryozoans *Escharopora* and *Rhinidictya* cf. *mutabilis.* The Mississippian of Kansas yielded the plant spores *Sporangites huronense;* and the Pennsylvanian the foraminiferan *Fusulinella haworthi.*—*D. J. MacNeil.*

11255. MILOJKOVITCH, M. Notes sur le terrain houiller de la Bosnie-Herzegovine. *Congrès Avancement Études Stratigraphie Carbonifère, Heerlen Compte Rend.* 1927. pp. 487-491. 1928.—Records from the Carboniferous of Bosnia and Herzegovinia plants, a crinoid, a bryozoan, brachiopods, pelecypods, gastropods, cephalopods, ostracods, and a trilobite.—*D. J. MacNeil.*

11256. MOORE, RAYMOND C. Environment of Pennsylvanian life in North America. *Bull. Amer. Assoc. Petrol. Geol.* 13(5): 459-487. 3 fig. 1929.—States that the study of plant and animal fossils to determine environmental conditions is based chiefly on observations of the influence of environment upon the present-day flora and fauna. The large, thin-walled cells of the woody plants of the Pennsylvanian of North America, and the absence of growth rings, indicate equable climatic conditions. Stresses the importance of the lime-secreting algae *Chara, Halimeda,* and *Osagia* in the formation of Pennsylvanian limestones; asserts that bacteria are also important in interpreting the environmental conditions of that period, and that the formation of oolites in several horizons may be attributed to them. The significance of the presence of such fresh-water pelecypods as *Naiadites, Anthracomya,* and *Carbonicola,* as well as every type of marine invertebrate, is treated in detail. Points out that some wide-spread deposits are characterized by a fauna with peculiarities not common to types found in the preceding or succeeding beds; for example, the occurrence of the brachiopod *Marginifera splendens* in the Brownville bed. Vertebrate remains are not common in the marine rocks of this period, but selachian teeth and a few ichthyodorulites are found. Fish remains, when found, are usually in limestones.—*D. J. MacNeil.*

11257. NIGHTINGALE, W. T. Geology of Vermilion creek gas area in southwest Wyoming and northwest Colorado. *Bull. Amer. Assoc. Petrol. Geol.* 14(8): 1013-1040. 3 maps, 3 fig. 1930.—Records from the Eocene series of this region vertebrate bone fragments, and the mollusks *Unio, Viviparus, Goniobasis,* and *Ostrea.*—*D. J. MacNeil.*

11258. ØDUM, HILMAR. Vort sydligste Danium. [Our most southerly Danian.] [German summary.] *Meddel. Dansk. Geol. Foren.* 7(3): 201-214. 1928.—Lists from different Danian horizons of Denmark a large number of fossils—an anthozoan, Hydrozoa, Vermes (Chaetopoda), Crinoidea, Asteroidea, Brachiopoda, and Pelecypoda.—*F. Anderegg.*

11259. ROTH, ROBERT. Regional extent of Marmaton and Cherokee mid-continent Pennsylvanian formations. *Bull. Amer. Assoc. Petrol. Geol.* 14(10): 1249-1278. Map. 1930.—Records many brachiopods, cephalopods, gastropods, and ostracods from the Pennsylvanian of Oklahoma, Kansas, and Nebraska. Stresses their utility in correlating the different formations, referring especially to the foraminiferan *Fusulinella* sp., an undescribed "new sp." *F. hartvillensis,* and the brachiopod *Chonetes* sp. States that plant remains are also present.—*D. J. MacNeil.*

11260. SHEPPARD, GEORGE. Geology of southwest Ecuador. *Bull. Amer. Assoc. Petrol. Geol.* 14(3): 263-309. Map, 21 fig. 1930.—Records from the Quaternary of this region the pelecypods *Arca* and *Cardium,* and the gastropod *Turritella;* states that the Tertiary contains radiolarians, and lists from it the foraminiferans *Discocyclina, Nummulites, Operculina, Orthophragmina peruviana* (?), and *Lepidocyclina* cf. *peruviana,* and the pelecypods *Inoceramus roemeri, I. plicatus, Cyprina* (?), and *Phacoides subpennsylvanicus.*—*D. J. MacNeil.*

11261. STEWART, ROSCOE E., and KATHERINE C. STEWART. "Lower Pliocene" in eastern end of Puente Hills, San Bernardino County, California. *Bull. Amer. Assoc. Petrol. Geol.* 14(11): *map.* 1445-1450. 1930.—Asserts that this formation is Lower Pliocene rather than Upper Miocene, as mapped by a previous author. Submits a list of Lower Pliocene micro-fauna in support of this statement, including 44 spp. of Foraminifera; 2 of which, *Frondicularia advena* and *Bolivina subadvena,* are new varieties to be named, described, and figured in a subsequent paper. States that diatoms and echinoid spines are also present.—*D. J. MacNeil.*

11262. VON ESTORFF, FRITZ E. Kreyenhagen shale at type locality, Fresno County, California. *Bull. Amer. Assoc. Petrol. Geol.* 14(10): 1321-1336. 5 fig. 1930.—Lists 27 spp. of Foraminifera from Tertiary formations of this region; remarks that Radiolaria belonging to the sub-order Spumellaria are plentiful; and records 13 spp. of mollusks, only 1 of which, *Pecten interradiatus,* was found in the shale. States that fish scales are common, and refers to the occurrence of an undescribed fossil leaf. Includes an incomplete list of genera of Foraminifera from west coast Eocene, Oligocene, and Miocene formations.—*D. J. MacNeil.*

GENERAL

11263. BRITES, GERALDINO. O ensino da morfologia humana. Notas colhidas numa viagem de estudo (22 de Janeiro-12 de Abril de 1928). [Instruction in human morphology. Notes collected during a travel study, January 22 to April 12, 1928.] 208p. 9 fig. Imprensa de Universidade: Coimbra, 1929.—The author visited the medical schools and various biological institutes of Paris, and the medical schools of Bordeaux, Strassbourg, Tours, Nancy, Salamanca, Valladolid, Brussels, and Prague on a tour of observation and conference on aims and methods in the study of human anatomy, gross, microscopic, and pathologic. The opening chapter is a summary of opinions, largely published in the last quarter century, by others than anatomists on the exhaustion and futility of morphological, i.e., anatomical instruction and research. This is followed in chapters 2 and 3 by many authorities and by full consideration from different points of view of the interdependence of anatomy, sensu latu, with physiology, pathology, surgery, and clinical medicine. The 4th chapter discusses the future of anatomy, histology, embryology, and pathology, with examples giving current trends. Chapter 5 is a detailed discussion of content of courses, equipment, and methods in the institutions visited. The 6th chapter is an extended account of methods and preservatives used in the preparation of macroscopic museum material in anatomy and pathology. A closing chapter describes and illustrates the new Institutes of Histology and Embryology and of Pathology of the Medical School at Prague.—*C. A. Kofoid.*

11264. BROOM, ROBERT. The origin of the human skeleton. An introduction to human osteology. 164p. 2 pl., 46 fig. H. F. & G. Witherby: London, 1930. Pr. 10s. 6d.

11265. CHEESMAN, J. E. Baillière's synthetic anatomy. I. Upper arm and shoulder. II. Forearm. III. Hand. IV. The thigh and hip. V. The leg. VI. The foot. VII. The thorax. VIII. The abdomen. IX. Head and neck. IXa. Pterygo-maxillary region. 60p. 120 pl. Thomas Nelson & Sons: New York, [1928?].—Each part contains "a series of drawings on transparent sheets for facilitating the reconstruction of mental pictures of the human body." A set of 12 plates represents consecutive layers through the region represented; these are correlated by an ingenious system of coördinates, and, viewed together, give the appearance of a transparent reconstruction. Mimeographed instructions accompany the series.—*H. B. Baker.*

[Anatomical analysis of roentgenogram shadows of the heart and of the interlobar fissures of the lungs.] 127p. 32 roentgenograms, 46 sketches, 2 fig. Gustav Fischer: Jena, [1929]. Pr. 24 M.

11268. STÖHR, PHILIPP (W. v. MÖLLENDORFF, editor). Lehrbuch der Histologie und der mikroskopischen Anatomie des Menschen. [Histology and microscopic anatomy of man.] 22nd ed. 522p. 446 fig. Gustav Fischer: Jena, 1930. Pr. 21 M.

11269. TERRY, ROBERT JAMES. An introduction to the study of human anatomy. 346p. Macmillan Co.: New York, 1929. Price $3.50.—The book is based upon a series of mimeographed laboratory directions used for many years by classes at the Washington University, School of Medicine. The object of the book, besides serving as a guide in dissection, is to stimulate an increased interest in the study of anatomy and to offer the beginner in medicine a broad view of the field and of investigations in progress in anatomy. To this end attention is called to studies of human structure pursued in laboratories of embryology, anthropology, genetics, and other biological fields. Emphasis is laid on verification and research—verification by subsequent study of textbooks and other sources of information; research by the introduction of simple problems bearing on the subject of dissection. The directions given are based upon the examination of one part of the body at a time and not upon the simultaneous study of several parts. The book is divided into 5 sections dealing respectively with the lower limbs, the upper limbs, the back and thorax, the abdomen, and the head and neck. In each case the order of study is as follows: integument, subjacent soft parts, special preparations of muscles and viscera, the articulations, the skeleton, and the surface anatomy of the living body. The central nervous system is omitted. Bibliographical and biographical references are included in every section. The Basle Anatomical Nomenclature in both Latin and English is used throughout. The directions accompanying the early dissections are extensive but are gradually reduced as the student gains more experience. There is an index of personal names and also a complete subject index.—*P. Okkelberg.*

11270. WARREN, JOHN (text by ROBERT M. GREEN, and drawings by H. F. AITKEN). Warren's handbook of anatomy. Adapted for dissecting and clinical reference. xiv+384p. 324 fig. Harvard University Press: Cambridge, 1930. Pr. $12.50.—The book is divided into 8 parts, dealing respectively with the gross structures of the following regions: (1) head and neck, (2) trunk, (3) upper extremity, (4) lower extremity, (5) thoracic cavity, (6) abdominal cavity, (7) pelvic cavity, (8) perineal region. The illustrations are original and made from actual dissections under the direction and observation of Warren. They aim to show all the main anatomical features in their actual positions and relations to other parts. The text is brief but

adequate and is designed to make the volume usable as a handbook for dissection in a first year course in human anatomy and as a reference book for the surgeon and general practitioner. For the illustrations the Basle Nomina Anatomica are used and in the text the Latin equivalent of each English term appears at least once. There is a separate and complete index of English and Latin terms used.—*P. Okkelberg.*

EXPERIMENTAL ANATOMY AND REGENERATION

11271. ĀBOLIŅŠ, LEO. Die Regeneration der am Fibularrande verstümmelten Beine bei Triton cristatus Laur. *Zeitschr. Wiss. Biol. Abt. D, Roux' Arch. Entwicklungsmech. Organ.* 122(2): 213-229. 8 fig. 1930.—Fifty *T. cristatus* were operated upon as follows: in 10, fibula and fibular region were excised (series B); in 10 the 5th toe and corresponding part of the tarsus (the fibulare, the partially or wholly fused 4th and 5th tarsals) were excised (series C); in 10, the whole fibular side, from knee-joint to 5th toe inclusive, was removed (series D); in 10, only the 5th toe (series E), and finally in 10, the fibula was excised and the 5th toe removed (series F). Series A, of normal animals, was used as a control. When the fibula with its whole surrounding region was removed, a long fibula-like bone regenerated in over 50% of the cases; a result directly opposed to that secured when the bone alone is extirpated without injury to the fleshy parts of the extremity. Such restitution excludes the possibility of super-regeneration. In the other 50% of cases the fibula is replaced by an abnormal distal regenerant of half the normal cross-section arising from the knee. A typical leg, of half diameter, may arise as a distal regenerant from the knee if only the fibula and surrounding soft parts are excised and the whole primary foot is left untouched; although development of the distal regenerant is greatly stimulated by removal of the primary foot. An otherwise complete and skeletally typical limb, growing as a distal regenerant from the knee region, shows only a reduplicated element. Whether a typical foot can result as a lateral regenerant from the tarsus and the region of the fibula remains unanswered. The results of the experiments would tend to support this assumption, especially for the tarsus; further experiments are necessary. A distal regenerant predominates over a possible proximal regenerant in all regions of the reduplicated or primary foot. Regeneration of the toes can be suppressed by the other regenerative processes. Typical triple-reduplication could be produced experimentally on the reduplicant and the tarsus by excision of the corresponding parts of the edge of the fibula.—*From author's summary (transl. by E. W. Count).*

11272. CRACIUN, E. C. Glycogénie et régénération des muscles volontaires. (Glycogenesis and the regeneration of voluntary muscles.) *Arch. Roumaines Path. Exp. et Microbiol.* 2(2/3): 313-324. 1929.—1500 gm. rabbits (1) received in thigh muscles 0.5 cc. 50% alcohol—1% formalin—India ink (controls received dist. H_2O), or (2) had thigh muscles surgically damaged. Histological examination of sections after 1, 2, 4, 9, 11, 16, 28 days showed glycogen in muscle bundles (wide variations being normal) but not in sarcoblasts or granulated tissue. The author believes the elements regenerating striated muscles do not have a positive carbohydrate balance, since they have no free glycogen reserve. A brief review of the subject is included.—*S. M. Field.*

11273. GAETANI, G. de. Innesto di tessuto pancreatico nelle ghiandole salivari. [Grafts of pancreatic tissue in salivary glands.] *Boll. Soc. Ital. Biol. Sperim.* 5(5): 773-775. 1930.—Pancreatic tissue grafted into the salivary glands of 4 dogs underwent rapid dissolution, the regressive processes being complete after 10 days, and connective tissue replacing the pancreatic tissue. In 4 other dogs, grafted with pancreases which had previously undergone atrophy of the exocrine portion through ligature, the same results were obtained.—*M. Comel.*

11274. MIDANA, ALBERTO. L'influenza dell'età sulla rigenerazione dei nervi periferici. [Influence of age on regeneration of peripheral nerves.] *Arch. Sci. Med. [Turin]* 54(11): 774-780. 2 fig. 1930.—Regeneration of peripheral nerves, especially the first stage, proceeded more rapidly in 10 rats during the period of development and growth; but regeneration occurred also in 8 mature and 10 senescent rats.—*M. Comel.*

11275. PERACCHIA, GIAN CARLO. Il "sistema-reticolo-endoteliale" nel processo di riparazione delle fratture. [The "reticulo-endothelial system" in the repair of fractures.] *Rev. Sud-Americana Endocrinol.-Immunol. Quimioter.* 11(8): 519-553. 23 fig. 1928.—From the results of his experiments on the fractured bones of the left foreleg of 12 rabbits the author concludes: at the site of fracture the osteoblastic elements replace the active macrophagic elements. The osteoblasts appear blue due to the presence of granules of trypan blue, used as a stain. These cells lose the stain when they develop definite functional and morphological characters, hence vital staining with trypan blue is a characteristic of the specific elements of transforming tissue, not of mature tissue. In healing fractures, both the intra-cartilaginous and intramembranous types of ossification are found, although at first only the latter type seems to be present. The cartilage cells appear at a later stage. The healing process starts in the resting embryonal elements of the "subperiosteal marrow" and in the Haversian Canals.—*N. Colosi.*

11276. SCIACCHITANO, IGINIO, PAUL WEISS, und HANS PRZIBRAM. Die Regeneration der am Tibialrande oder median verstümmelten Beine bei Triton cristatus Laur. und eine Heteromorphose des langen Knochens nach Ausschneidung des Fibularrandes. *Zeitschr. Wiss. Biol. Abt. D, Roux' Arch. Entwicklungsmech. Organ.* 122(2): 300-315. 37 fig. 1930.—17 series of operations were performed in all. The tibia of an adult, excised with the whole of the tibial region, was not regenerated even after 2 mos. Feet and toes arose as distal regenerants, after excision of the tibia and of the surrounding soft parts, from the transverse cut surfaces at the knee. No reduplicated element replaced the tibia. Lateral mirror-image reduplication from the fibula was not found; the lateral toes arising at the end of the fibula are in most cases not distinguishable as definite parts of the foot, the symmetry of which is uncertain. Distal regenerants from a transverse knee cut had in most cases fewer toes than the toe-groups arising laterally from the longitudinal tarsal cut after the same operation. 1 or 2 toes regenerate normally after simple transverse removal. Typical partial 3 fold growth could be experimentally produced in the reduplicant and the tarsus by excision of the corresponding tibial border. While simple transverse amputation, at its base, of the middle toe led to its regeneration without change, a reduplication of the toe occurred when the transverse cut was split even as far as the reduplicant. When deep cleavage is combined with removal of one of the longitudinal halves thus produced, lateral parts of the foot were formed at the tarsus and a distal regenerant, from the knee cut. This work, and that of Āboliņš, shows that the symmetry of partial 3-fold reduplication follows Bateson's rules if, between 2 distally growing surfaces, a proximally directed cut surface is interpolated, but not otherwise. One of Weiss' cases, in which, after the excision of the fibular side including the 5th toe, an undoubted tibia (apparently the mirror-image of the original) was formed in place of the fibula, is important in understanding the symmetry of a laterally developing limb-bud. This establishes the occurrence of such regenerative reduplication, which moreover includes the foot and toes; and the drawings of Āboliņš of long bones regenerated in place of the excised fibula point in the same direction.—*Authors' summary (transl. by G. L. Purser).*

11277. VIZIOLI, FRANCESCO. Osservazioni sulle ferite cerebrali degli animali neonati. [Cerebral wounds in new-born animals.] *Boll. Soc. Ital. Biol. Sperim.* 5(6): 1028-1031. 1930.—Cerebral wounds are followed

in new-born animals by repair processes different from those of adult animals. More phagocytic cells are described in wounds of the white than in the gray matter. In wounds of the gray matter cells with granular and fatty contents are lacking, while phagocytic elements from the blood stream are present.—*M. Comel.*

HEMATOLOGY (INCL. RETICULO-ENDOTHELIUM)

11278. **BLOUNT, W. P. Studies on comparative haematology: 1. The differential and polynuclear counts of veterinary students.** *Vet. Jour.* [*London*] 87(5): 215-222. 1931.—14 "physiologically healthy" students presented a differential count of: neutrophils, 62.23; eosinophils, 3.2; basophils, 0.72; lymphocytes, 28.75; monocytes, 5.1. The weighted mean (Arneth counts) of these students averaged 2.02. This variation from Cooke's average of 2.70 is due to: improved nuclear staining with increased definition of chromatin filaments; the adoption of a more clearly defined "standard" filament; the exclusion of "hidden lobes." Evidence is produced which shows that the weighted mean may be altered by exercise to a considerable extent; this does not concur with Ponder's statement concerning the "steady state" of the "Arneth" count.—*Author's summary.*

11279. **FERRARI, R. Sulla divisione diretta degli eritrociti circolanti della rana.** [Direct division of circulating erythrocytes in frog.] *Boll. Soc. Ital. Biol. Sperim.* 5(1): 11-14. 1930.—In the perfused frog a very active process of proliferation through amitosis may be experimentally induced in the circulating erythrocytes. The erythroblasts proliferate, however, through karyokinesis. The amitosis is not due to senescence or to cellular degeneration; in the erythrocytes the faculty of reproduction is perfectly conserved and takes place by amitotic division. It does not interfere with proliferation and maturation of the erythroblastic series as they depend on karyokinesis. The phases of amitotic reproduction of erythrocytes of perfused frogs are identical with those observed under normal conditions in erythrocytes of fishes.—*M. Comel.*

11280. **FERRARI, R. Ricerche ematologiche sulla rana salata. Eritropoiesi ed eritremia sperimentale.** [Hematological research on salined frog. Experimental erythropoiesis and erythremia.] *Haematologica* 12(1): 19-44. 2 pl., 16 fig. 1931.—By perfusing frogs with diluted (½) Ringer's solution through the abdominal vein a severe anemia was produced which lasted for several months. Red cells were reduced from 400,000 to 3-6,000 per cu. mm., the vast majority being in an immature stage. The white corpuscles showed anisocytosis with micro- and macro-leucocytosis of neutrophils. Despite a marked hyperplasia of the erythropoietic tissue in the bone marrow, spleen, liver and kidney, the red cells were unable to reach maturity—a phenomenon explained on the basis that frogs, deprived of their normal nutrition, seek to construct the hemoglobin molecule from their own tissues.—*N. A. Michels.*

11281. **GLATZEL, HANS. Der Anteil von Erbanlage und Umwelt an der Variabilität des normalen Blutbildes.** *Deutsches Arch. Klin. Med.* 170(4): 470-489. 1931.—By comparison of uniovular (U.T.) and biovular (B.T.) pairs of twins the author determined the rôle played by inheritance and environment in variability. Material consisted of 44 U.T., 37 like-sexed B.T. and 11 unlike-sexed B.T., all healthy. The Hb content, the number of erythrocytes and leucocytes and the differential count were determined under physiological conditions. For every pair of twins an average percentage deviation for each of the 3 groups was determined. This deviation of B.T. differed from that of U.T. and was greater in respect to Hb, red cells, neutrophils and monocytes. A less marked difference was found in lymphocytes; there was no difference in total white cells or in eosinophils or basophils. The variability concerning the participation of environment in the characteristics of B.T. was determined in percentage of total difference of B.T. These were: 42 Hb, 49 red cells, 92 total leucocytes, 63 neutrophils, 68 lymphocytes, 61 monocytes, 85 eosinophils and 88 basophils. From the ratio of discordant U.T. and B.T. the influence of inheritance and environment on blood picture was calculated. This environmental factor expressed in percentage difference of B.T. was 23 Hb, 43 red cells, 70 total white cells, 41 neutrophils and 37 lymphocytes. The divergence of the values mentioned above is explained by the fact that methodical errors are charged to the environmental factor. In the inheritance investigations, therefore, the Hb content is particularly serviceable but the total number of red cells and the relative number of lymphocytes and neutrophils are also of use. For this purpose the relative number of other leucocytes and the total white count are of little or no use.

11282. **KATZENSTEIN, RUTH. Untersuchungen über die Umwandlungsfähigkeit der Lymphzellen.** *Virchow's Arch. Path. Anat. u. Physiol.* 281(1): 172-190. 6 fig. 1931.—Maximow's celloidin chamber was introduced into the intermuscular abdominal connective tissue of rabbits. Development of inflammatory cells was studied in the fissures of the chamber and the surrounding tissue. Leucocytes and lymphocytes appeared very early. While later leucocytes disappeared, lymphocytes changed into polyblasts and assumed macrophagic qualities. Later on polyblasts were not to be found and only fibroblasts and histiocytes were seen on the inflammatory field. Buffy coat of the blood of adult rabbit was explanted into plasma of the same animal without addition of extract. After growth of ½ hr. to several days the explants were studied in vivo, by supravital-staining with Janus green and Neutral red or in serial sections. Leucocytes and lymphocytes moved into the plasma, leucocytes degenerated, lymphocytes and the few monocytes developed into large macrophagic cells, polyblasts, which finally became typical fibrocytes.—*R. Katzenstein.*

11283. **KINDRED, J. E., and E. L. COREY. Studies on the blood of the fetal albino rat. II. The hemoglobin content of the blood as related to the differential erythrocyte count.** *Physiol. Zool.* 4(2): 294-301. 1931.—The concentration of the hemoglobin in grams per 100 cc. of whole blood was determined in fetal albino rats ranging in crown-rump length from 15.4 mm. to 43 mm. (birth). Also total counts of the red blood corpuscles per cu. mm. and differential counts of the different types of red corpuscles were made on each rat. The total number of red blood corpuscles per cu. mm. increases from the youngest stage to birth. The hemoglobin content shows major fluctuations correlated, not with the increase in the number of corpuscles, but with the degree of polychromasia of the blood. Normoblasts and erythroblasts decrease in incidence toward the end of gestation and are numerically insignificant after the fetus is about 35 mm. long. There is no correlation between the red-blood-corpuscle count or the hemoglobin content of the blood of the pregnant albino rat and the number or size of the fetuses in utero.—*Authors* (*courtesy Wistar Bibl. Serv.*).

11285. YAMAGUCHI, M. Zytologische und histologische Untersuchungen von Milzkulturen der eben geborenen Ratte. *Arch. Exp. Zellforsch. Bes. Gewebezücht. (Explantation).* 10(1): 43-72. 16 fig. 1930.—The spleen of a newborn rat was cultivated in plasma and plasma with spleen extract and with bone marrow extract, after the method of Erdmann. Cultures were examined either fresh, stained in toto, or in celloidin serial sections stained with eosin-azure. The newborn rat spleen was not yet wholly differentiated; it consisted of dark fields, in which erythropoiesis, granulopoiesis, and lymphopoiesis were recognizable, and of light fields with thick mesenchyme cells and reticular cells near the vessels. A few fibrocytes were seen in the capsular tissue. With advance in culture life, the granulocytes and agranulocytes gradually degenerated; phagocytosis by reticular cells and transplantation gradually removed them from the explant. From the 1st day on, the reticular cells became rounded and swollen, wandered in the surrounding plasma medium and within the newbuilt tissue, where they phagocytosed many disintegrated elements in the old tissue fragments and in the zone of migration. In the old and in the newbuilt tissue the reticular cells did not assume such strongly ameboid or elongated forms, but were usually round; on the other hand, on the rim of the tissue and in the fibrin they assumed a very different aspect by extending their pseudopodia; on the upper surface of the cover glass they became hypertrophied and often formed polynuclear giant cells. The mesenchymal cells of the tissue always multiplied; at first they clothed the explant like a capsule and from there grew directly into the growth zone; on the upper surface of the medium they were extended, while in the interior of the culture or on the cover glass they were membranous, or syncytial in shape. By the 6th day the explant contained only mesenchymal and reticular cells. Throughout these experiments the mesenchymal and reticular cells remained distinct and no transitions between reticular cells and fibrocytes were observed. —*Author's summary (transl.).*

11286. ZALKA, EDMUND von. Blutkörperchenzahl und Organveränderungen nach Luftverdünnung und das reticuloendotheliale System. *Zeitschr. Ges. Exp. Med.* 76(1/2): 120-135. 6 fig. 1931.—The reticulo-endothelial system of 5 guinea pigs was blocked with 8-36 cc. 10% Fe saccharatum solution intraperitoneally; 6, with 5.5-7.5 ccm. 5% lithium carmin; 3 rarefaction controls; all but injected controls were subjected to an atmosphere of 300-320 mm. Hg (representing an elevation of 7000 m. and 8-9% O). Fe guinea pigs were killed after 3 days rarefaction, the carmin after 2-4 days, controls after 3 days. A decrease in red blood cells occurred in blocked animals after rarefaction, while the untreated showed increase; this was not caused by the block itself. Histologic examinations of liver, spleen, and medulla of femur were made of all blocked and treated animals, 4 controls treated but not blocked, and 2 which came from an elevation of 106 m. In the femurs (compared with those from 106 m.) a pronounced proliferation of the medulla was found, both in blocked and control animals; little difference was found in the spleens, nucleated red blood cells, mitoses, and megakaryocytes being present; in the liver no pathologic alterations were found in the animals injected with Fe. The author suggests that the fluids injected produced a thickening of the capillary endothelium so that the excess red blood cells, formed in the bone marrow under the influence of rarefaction, could not be carried away.

VASCULAR SYSTEM (INCL. LYMPHATICS)

11287. DENTICI, LORENZO. La struttura delle vene cave nelle varie età dell'uomo. [Structure of the human vena cava at different ages.] *Monitore Zool. Ital.* 40(11/12): 570-571. 1930.—The middle muscular layer is wanting in the new-born and in children; it is always present in adolescence and youth and then diminishes, so that it is always absent in old age. The connective tissue of the adventitia increases with age and the elastic tissue increases up to about 50 yrs., when it begins to lessen.—*E. Padoa (transl. by J. P. McMurrich).*

11288. KAHN, R. H. Die Blutdruckregler. *Zeitschr. Ges. Exp. Med.* 68(1/4): 201-215. 16 fig. 1929.—The term "pressure regulators" is suggested for those afferents arising from receptors in the walls of the aorta and carotid bulbs, the function of which is to reduce blood pressure changes in the aorta to a physiological minimum. The aortic regulators run in the vagi and the carotid regulators in the glossopharyngeals or possibly adjacent systems.—*W. J. Meek.*

11289. PATTEN, BRADLEY M. The closure of the foramen ovale. *Amer. Jour. Anat.* 48(1): 19-44. 7 fig. 1931.—Hearts of over 160 infants from birth to 2 yrs. were studied. Measurements of the functional orifice of the foramen ovale at ages from birth to 9½ mos. are given in a table. The postnatal abandonment of the foramen ovale in man is not immediate and abrupt, but is a gradual process paralleling increase in pulmonary circulation and decrease in the bore of the ductus arteriosus. While the events leading toward closure form a continuous sequence, 3 phases of the process may be distinguished: (1) Reduction of fullness of valvula with concomitant diminution in size of effective interatrial orifice. These changes are indicative of gradual cessation of compensatory interatrial blood flow, and culminate in "functional closure" of the foramen about 1 month after birth. Then follows, (2) a period from the 2nd to 8th or 9th month in which rapid connective-tissue growth (±600% increase) reflects the conversion of the formerly movable valvula into a passive septal structure. This phase merges into, (3) the period of fibrous adhesion of the valvula to the septum. There is great variability in the age at which final incorporation of the valvula as an integral part of the septum occurs. As a rule, adhesion is completed during the latter part of 1st or beginning of 2nd year. In many instances it is delayed beyond this period, and in approximately 25% of all individuals fusion is never absolutely completed. A small "probe-patency" persisting beneath a competent valvula causes no functional difficulties and should be regarded as a variant of the normal rather than as pathological.—*Author (courtesy Wistar Bibl. Serv.).*

11294. BRUHNKE, JOHANNES. Ueber den Mechanismus des Pferdehufes. [Mechanism of the horse hoof.] *Berliner Tierärztl. Wochenschr.* 47(30): 485-487. 12 fig. 1931.

11295. ERICKSON, THEODORE C. The postnatal development of the caudal integument in the rat. *Amer. Jour. Anat.* 47(1): 173-193. 2 pl. 1931.—In a macroscopic and microscopic study in a series of rats from birth to maturity 2 strains (Wistar strain of *Mus norvegicus albinus* and Long-Evans strain of hybrid (pied) rats) were used. The first hairs ("middle hairs" of Römer), which appear on the tail at about 6 days after birth, are arranged in equidistant rings around the tail. The "first collateral hairs" appear at 10 or 12 days and the "second collateral hairs," in the 3rd week. After development is complete the most common number of hairs emerging from under each scale is 5 in the proximal and 3 in the distal part of the tail. The formation of scales is secondary to that of the hairs. The total number of scales in the adult tail is about 3000. Coincident with a decrease in mitoses there is a decrease in thickness of the stratum germinativum from birth to maturity. The caudal epidermis of the newborn rat contains a very prominent stratum granulosum which later disappears. In the newborn there are no visible nuclear remnants in the stratum corneum, while in the adult there are flattened pycnotic nuclei. Arterioles and precapillaries with a lumen of not more than 8μ in diam. have a definite elastic lamina similar to that in the larger vessels. Elastic tissue is abundant in the internal and external elastic lamina in the larger arteries, but is entirely absent from the media.—*Author (courtesy Wistar Bibl. Serv.).*

11296. FRASER, DORIS A. The winter pelage of the adult albino rat. *Amer. Jour. Anat.* 47(1): 55-87. 1 pl., 7 fig. 1931.—The ratio of weight of the winter pelage of the mature albino rat to body weight is 15.7 mgm.: 1 gm., and to body surface, 9.64 mgm.: 1 sq. cm. In all hairs the ratio of breadth of shaft to medulla is 1.6-1.4: 1. The follicles are aggregated mostly into 2 types of groups, those with and those without a central follicle, the latter being more plentiful. Follicles contain 1-5 hairs. The hairs in groups with a central follicle average 13.9 on the dorsum and 17.2 on the venter, distributed in 6.05 and 7.4 follicles, respectively. Hairs in groups without a central follicle average 8.7 on the dorsum and 9.7 on the venter, distributed in 3.8 follicles in both cases. There are 7.7 groups, 35.75 follicles, and 85.65 hairs to an average sq. mm. of dorsal skin and 11.5 groups, 54.7 follicles, and 152.6 hairs to an average sq. mm. of ventral skin. It is estimated that the body hairs number 5,028,303 in the ♂ albino rat of 230 gm. of body weight. After clipping areas on the dorsum always a few hairs grew to the usual length of hairs on this surface within a month. The large hairs which could be identified day after day averaged nearly a millimeter growth per day.—*Author (courtesy Wistar Bibl. Serv.).*

11297. FUKUI, KEN-ICHI. The definite localization of the color pattern in the goldfish. *Folia Anat. Japonica* 8(3/4): 283-312. 29 fig. 1930.—The mode of spreading of pigment of the goldfish is similar in both the black and red patterns. According to their distribution they can be divided into the dorsal, lateral and ventral patterns. The dorsal pattern of the head is separated into 2 parts. The snout pattern spreads from its center on the jaw, but is restricted to the snout. The head pattern spreads from its center at the intersection of the dorsal median line and the boundary between the head and the back; it is always restricted by the junction of bones of the skull underneath. The largest covers the whole surface of the skull. The dorsal pattern of the trunk is usually limited to the dorsal side of the lateral line, and is separated into 4 definite parts. The neck pattern spreads caudally from the same center as the head pattern and covers the anterior part of the back anterior to the dorso-ventral (transverse) scale line (Dvl) 7. The back pattern accompanies usually the neck pattern; its center lies before the anterior end of the base of the dorsal fin and it covers the middle part of the back between Dvl 7 and Dvl 16-19. The tail pattern has its center behind the posterior end of the base of the dorsal fin and spreads over the posterior part of the back posterior to Dvl 16-19. The terminal pattern, produced on the dorsal margin of the base of the caudal fin, sometimes accompanies the tail pattern and sometimes does not. The extension of each dorsal pattern often corresponds to the arrangement of each part of the dorsal musculature such as D.1, D.2 and D.3. (Dorsal muscles, D.1 being the long. muscle nearest mid-dorsal line, etc.) The lateral pattern in the head is limited to the opercular pattern; it is divided into 3 parts: the dorsal, restricted to the superior part of the operculum (Sop); the lateral, on either side of the junction between middle part of the operculum (Op) and subopercular (Sbb); and the ventral, along the ventral part of both operculum and Sbb. The lateral pattern in the trunk is limited to the flank pattern. Its center lies at the point where the ventro-caudal (oblique) scale line (Vp-Obl) 7 and ventral (longitudinal) scale line next to the scale line bearing the lateral canal system (Val) or ventral (longitudinal) scale line next to Val (Vbl) cross each other. It spreads over the abdominal bulge, being limited cranially by Vp-Obl 6, caudally by the furrow behind the abdominal bulge, dorsally by the lateral line and ventrally by the line drawn through the bases of 3 fins along the ventral median line. The ventral pattern, limited to the trunk, consists of 3 different parts. The pectoral pattern has its center on the base of the pectoral fin and is limited to the surface of the pericardial cavity. The abdominal pattern has its center on the base of the ventral fin and is limited to the surface of the musculature of that fin. In its dorsal extension it covers the abdominal bulge corresponding to the surface either of the peritoneal cavity or of both the peritoneal cavity and the retroperitoneal organs. The anal pattern has its center on the base of the anal fin and spreads over the surface of the furrow behind the abdominal bulge. Thus each color pattern of the goldfish has its own center and spreads to certain restricted areas of the body. The spreading takes place always along the parts of loose subcutaneous tissues and is prevented by the close attachment of the skin to the substratum.—*Author's summary.*

11298. LI, WIN RANG. Über die Wurzelfestigkeit der Japanerhaare. [In Japanese, with German summary, p. 80-81.] *Japanese Jour. Dermatol. & Urol.* 30(7): 768-774. 3 fig. 1930.—The attachment of hairs from various parts of the body was tested in 100 Japanese (70 ♂, 30 ♀) with the Basler apparatus as modified by Sasakawa. It was strongest at the back of the head (av. 57.3 gm.), less at the crown of the head (av. 48.3), least on the lower leg (av. 41.2) and the forearm (av. 20.7). Individual variations but no sexual differences were apparent. For the hair of the head the firmness of attachment seemed about the same as in Chinese but much stronger than in Europeans (32.7 gm. according to Basler), while for the forearm and lower leg the root strength of the hairs was about equal in the Japanese and Europeans but stronger than in the Chinese (according to Basler, 13.5 gm. forearm, 28.9 gm. lower leg). —*From author's summary (transl.).*

11299. MANGANOTTI, GILBERTO. Osservazioni sulla così detta membrana basale e sul tessuto reticolare del derma nella cute normale ed in alcune dermatosi. Ricerche sui rapporti dermo-epidermici. I. [The so-called basal membrane and the reticular tissue of the corium in normal skin and in certain dermatoses. Relations between corium and epidermis.] *Gior. Ital. Derm. e Sifil.* 71(6): 1901-1916. 3 pl. 1930.—Study of the junction between epidermis and corium in 58 subjects, 12 normal and 46 affected with various dermatoses, failed to show a continuous thick stratum between the 2 tissues or any interlocking of connective fibrillae with epithelial cells. Instead, in contact with the basal stra-

tum of the epidermis was a layer of reticular tissue belonging to the dermal mesenchyme, not constituting a true membrane, but probably a particular arrangement (paralleled in many other parts of the body) of intercellular colloids with reference to the epidermis. In pathologic conditions this reticular layer sometimes ceased to be argentophil and became collagenized or hyalinized, and sometimes apparently increased in thickness by the packing on it of reticular fibrillae present in dermal infiltrates. While normally the reticular tissue (outside of the reticular layer) is limited to circumscribing the sudoriferous glands and the pilo-sebaceous and capillary follicles, in diseased conditions it is distributed abundantly among the cells of the infiltrates, giving rise to different structural types corresponding, not to particular forms of disease, but to various cytologic types of the mesenchymal cells.—*From author's summary (transl.).*

11300. NAKANISHI, K. A contribution to the histological study of fine nerve fibers in the sebaceous gland and the arrector muscle of hair of the human body. [In Japanese, with English summary, p. 119-120.] *Japanese Jour. Dermatol. and Urol.* 30(11): 1134-1137. 1 pl., 1 fig. 1930.—The author, using a modification of the impregnation method of Ramon y Cajal with the skin of the axilla (osmidrosis casea) and of the healthy scalp of patients undergoing operation, found that the sebaceous glands are served by their own nerve fibers. The ramifying nerve fiber bundle, derived from the subcutaneous gross nerve bundle nets, throws out branches partly to the hair follicles to make nets surrounding them and partly to the sebaceous glands. The fibers reaching the sebaceous glands make rough nets in the periglandular connective tissue, and their slender branches penetrate into the interlobular connective tissue. Here they break up into very fine fibers, making very complicated nets on the membrana propria glandis. These very fine nerve fibers sometimes end with a knot-like swelling, but sometimes bcome so attenuated as to be scarcely visible. No ending of the fine nerve fibers can be seen between or within the gland cells themselves. The arrector pili muscles are also cared for by their proper nerve fibers which pass through the muscle fibers spirally but nearly parallel to them and are traceable as fine spiral endings in the muscle fibers. Those nerve fibers distributed to the hair follicles, sebaceous glands and arrector pili muscles show intercommunication.—*From author's summary.*

11301. SHARPEY-SCHAFER, E. Observations on the relative rate of growth of the nails of the right and left hands respectively: on seasonal variations in the rate, and on the influence of nerve-section upon it. *Proc. Roy. Soc. Edinburgh* 51(1): 8-13. 1930/31.—In nearly every case the rate was faster in summer than in winter and faster on the right hand than on the left. But the thumb nails grew faster on the left hand than on the right both in summer and winter. The slowest rate of growth occurred in the nail of the little finger of the left side. The cutaneous nerves (ulnar) of this finger had been severed, and, with the exception of those which subserve pain, had not shown functional recovery. It is therefore probable that a trophic influence is exercised through the nerves upon the growth of the nail; the probability being supported by the fact that the little-finger nail on the left or de-nervated side not only exhibits a slower rate of growth but is distinguished from the corresponding nail on the normal side by being more flattened in form, rougher on the surface, and more brittle in texture.—*Author's summary.*

11302. SZODORAY, LEWIS. The structure of the junction of the epidermis and the corium. *Arch. Dermatol. and Syphilol.* 23(5): 920-925. 5 fig. 1931.—Observations of Ag-impregnated preparations convince the author that a complete and firm connection exists between epidermis and corium as manifested under physiologic and pathologic conditions.

11303. TANIGUCHI, TORATOSHI. Quantitative Untersuchung der Anhangsorgane der Haut bei dem japanischen Neugeborenen. *Folia Anat. Japonica* 9(3/4): 215-265. 1931.—The author determined the quantity of sweat glands, of sebaceous glands, and of mm. arrectores pilorum, and also counted the number of sweat glands in 15 regions of the body by means of the paper-weighing method, converting them into those of 1 sq. cm. of skin area. The sweat glands are most abundant on the flexor side of the leg (8.859 cu.mm. in 1 sq.cm.) and least on the abdomen (2.704 cu.mm.). The average number of sweat glands per sq. cm. varies from 2321 on the flexor side of the leg to 1018 on the chest. The average individual volume of a sweat gland is greatest in the skin of the lateral side of the thigh (0.004553 cu.mm.) and least in the abdomen (0.002589 cu.mm.). The sebaceous glands are most abundant on the vertex (2.601 cu.mm.) and least on the leg (0.084 cu.mm.). The largest individual sebaceous glands are in the skin of the vertex and the smallest in the leg. The individual volume of sebaceous glands and that of M. arrector pili vary according to the number of hairs forming a hair group. The Mm. arrectores pilorum are most abundant in the skin of the vertex (2,841 cu.mm.) and least in the abdomen (0.210 cu.mm.).—*Author (courtesy Wistar Bibl. Serv.).*

11304. TROTTER, MILDRED, and HELEN L. DAWSON. The direction of hair after rotation of skin in the guinea-pig: an experiment on hair slope. *Anat. Rec.* 50(2): 193-196. 2 fig. 1931.—In 15 guinea-pigs an area of skin in the middorsal region approximately 2 sq.cm. in size was rotated so that the cephalic and caudal poles were interchanged. Consequently, the direction of the hair on this area was reversed and in a position ideally adapted to test the hypothesis of Kidd and F. Wood-Jones. The animals were kept under as normal conditions as possible, which included both active and passive manipulations of the hair in a caudad direction. All were subjected to the experiment for 14 mos. and some are now in their 3rd year. The results are uniform; the hair has maintained its original direction, responding in no way to external, mechanical influences.—*Authors (courtesy Wistar Bibl. Serv.).*

BONES, MUSCLES, JOINTS, FASCIAE

11305. ANDRES, J. Variation der Phillips'schen Sehne. (Beitrag zu den atavistischen Aufteilungserscheinungen des Musculus extensor digitalis communis und seiner Sehne beim Pferd.) *Anat. Anz.* 72(1/3): 23-30. 1 fig. 1931.—The Philipps' tendons in a horse had a special fascial layer from the carpus which only distally or in the middle of the metacarpus is united with the abnormally developed lateral extensor tendon: on the left by taking up a fine branch of this tendon, on the right by complete fusion with it.

11306. [BALABAI, P. P.] БАЛАБАЙ, П. П. До гістологічної будови зябрових мускулів миноги. [Histologic structure of the gill muscles of the lamprey.] [German summary.] Записки Київського Товариства Природознавців (*Mém. Soc. Nat. Kiew*) 27(4): 28-45. 1 pl., 4 fig. 1929.—Gill muscles of *Lampetra planeri, L. fluviatilis,* and *Petromyzon marinus* show a high degree of differentiation, consisting of smooth and striated muscle. The latter consists of 2 types of fibers: so-called compact fibers rich in fibrils, and so-called "empty" fibers with fibrils only at the periphery. Both types of fibers of the gill muscles of *L. fluviatilis* have more fibrils than the corresponding fibers of *L. planeri.* This fact is correlated with the greater muscular activity of the gills of *L. fluviatilis* so as to supply more O_2 demanded by this larger organism. The constrictor of the gill slits of *L. planeri* and *L. fluviatilis* presents the most complicated structure. On the dorsal and ventral sides of the muscle the lateral part consists of compact fibers, the median of "empty" fibers; but at a distance from the dorsal and ventral sides of the muscle both types interlace and cross each other so that in the middle part of the muscle the position of the compact and "empty" fibers is reversed. Often a definite correlation was established between the function and histological structure of the separate muscles. The presence of so-

called empty fibers is taken as an indication of primitive traits.—*S. A. Corson.*

11307. **BAUER, C. Kann im Experiment parostaler Callus durch Einwirkung der Synovia erzeugt werden?** *Arch. Orthop. u. Unfall-Chir.* 29(2): 181-183. 2 fig. 1931.—The author perforated the joint capsule on the flexor side of 10 dogs, closed the wound, and injured the musculature of the thigh at once in 5, after the incision healed and later, in the others. In 8 others the joint capsule was opened by a cross incision and the corners sutured back to leave a window in the superior recess; 4 were injured immediately, 4 after 8 wks. At the end of 10 wks. roentgenograms revealed no callus. Necrotic muscle was then inserted through the windows into the flexor musculature in the region of the capsule; no calluses developed. Apparently a parosteal callus cannot be produced by contusion of the musculature and the action of the synovial fluid on it.

11308. **[DOLGO-SABUROV, B. A.]** ДОЛГО-САБУРОВ, Б. А. Роль мышц в морфогении скелета. (Сообщение 1-е). **[The rôle of the muscles in the morphogeny of the skeleton. (1st communication.)** [German summary.] Известия Научного Института имени П. Ф. Лесгафта (*Bull. Inst. Sci. Lesshaft*) 16(1/2): 123-159. 14 fig. 1930.—Histological examinations revealed that the morphology of the bone surface depends on the method of muscle attachment. A connection by means of tendon or fascia results in a local, concentrated pull on the point of attachment of the bone. This develops a protuberance, outgrowth, comb, or roughness of the bone. A direct attachment of the muscle on the periosteum gives a broad origin or insertion. This results in a concavity, indentation, or a smooth surface of the bone.—*S. A. Corson.*

11309. **FECI, LORENZO. Guarigione delle cavità ossee da svuotamento. (Studio sperimentale-clinico-radiologico.) [Repair of artificial bone cavities.]** *Arch. Ortopedia* 45(3): 351-408. 31 fig. 1929.—Cavities were produced in the head of the tibia in 10 rabbits, of which 1 died of infection; the others were killed 9, 18, 30, 35, 50, 60, 72, 82, and 97 days, respectively, after the operation. The bones were found to repair the cavities spontaneously, by growth of fibrous tissue derived from the medulla, the fibrous tissue later returning to a medullary structure. Growing and epiphyseal cartilage when removed from or near artificial cavities is not replaced in its original form but undergoes premature ossification. Radiographic studies in 5 clinical cases support the same conclusions.

11310. **GOFF, BYRON H. An histological study of the perivaginal fascia in a nullipara.** *Surg., Gynecol. and Obstetr.* 52(1): 32-42. 18 fig. 1931.

11311. **GRAHE, KARL. Beitrag zur Entwicklung der Nasennebenhöhlen.** *Acta Oto-Laryngol.* 15(2/4): 141-160. 16 fig. 1931.—In 6 rabbits the molars of the left side of the lower jaw were nipped off every 8 days from the 6th wk. on. The animals were killed after 4 mos., and the skulls of 3 macerated and the other 3 skulls decalcified and embedded in celloidin for histological examination. In all skulls, the left side was less developed than the right, especially in the region of the maxillary bone; histologically the bone was porous and the turbinals thickened; the right nostril of one was inflamed. In 5 other young rabbits, 1 nostril was sutured. No difference was found in the development of 4; the 5th was discarded because of suppuration. In both rabbits with inflamed nasal mucosa, the development of pneumatization was checked on the affected side.

11312. **INGALLS, N. WILLIAM. Observations on bone weights.** *Amer. Jour. Anat.* 48(1): 45-98. 1931.—The observations recorded are based on the dry weights of all the bones of the body, either individually or in functional groups, from a series of 100 adult white ♂♂ 19-78 yrs. old. Although there is much variation in the behavior of different bones, the tendency is for the weight to rise to what may be called the peak of development, decline then, and rise a second time as early age changes add to the weight, and finally subside in the atrophy of old age. Considerable differences are encountered not only in the reactions to age, but also in the variability of different bones. Upper and lower extremities are contrasted as well as the variations between right and left. Certain features may vary with race or sex and in many cases hereditary, phylogenetic influences appear to be at work.—*Author (courtesy Wistar Bibl. Serv.).*

11313. **JAZUTA, KONSTANTIN. M. glutaeus medius accessorius.** *Anat. Anz.* 72(1/3): 10-11. 1 fig. 1931.—In an adult man a true accessory median gluteal muscle was found, its base directed upward and forward, extending for 5.5 cm. along the outer surface of the ilium below the origin of Mm. tens. fasc. latae and glut. med.; backward and downward it extended to the trochanter major. The tendons divided, one fusing with that of the glut. med., the other attaching itself directly to the trochanter major. The muscle was about 10 cm. long, 1 cm. thick.

11314. **[KOTIKOVA, E. A.]** КОТИКОВА, Е. А. О деятельности M. serratus posticus inferior. **[Function of M. serratus posticus inferior.]** [German summary.] Известия Научного Института имени П. Ф. Лесгафта (*Bull. Inst. Sci. Lesshaft* 16(1/2): 111-121. 3 pl., 2 fig. 1930.—Twelve human cadavers of both sexes and various ages were studied. Contraction of the muscle dilated the lower part of the thoracic cavity in 3 directions simultaneously, thus assisting inspiration.—*S. A. Corson.*

11315. **[LEBEDEVA, M. V.]** ЛЕБЕДЕВА, М. В. Соотношение между окраской и строением поперечнополосатых мышц в связи с их деятельностью и возрастом животного. **[Correlation between color and structure in striated muscle in connection with muscular activity and the age of the animal.]** [German summary.] Известия Научного Института имени П. Ф. Лесгафта (*Bull. Inst. Sci. Lesshaft*) 16(1/2): 213-236. 13 fig. 1930.—In the cat and rabbit striated muscles of different color and structure develop from the pale muscle which forms all the musculature of the newborn but which is structurally very different from white muscle of the adult. The color change does not begin simultaneously in all the muscles; but the intensity of the color increases with age at a rate directly proportional with the activity of the muscle. Often in dynamic and static muscles the color does not coincide with the structure, "red" muscle having the structure of "white" muscle and vice versa. All dynamic muscles consisting of long parallel fibers in adult animals have the typical structure of white muscle regardless of the color, while static muscle, consisting of short fibers, exhibits mostly a typical structure of red muscle. Identical muscles of different animals of the same species in most cases have the same color and structure. Identical muscles of animals of different species often exhibit different color and structure.—*S. A. Corson.*

11316. **MEYER, A. W. Our inadequate terminology concerning the anterior palatine region.** *Anat. Rec.* 49(1): 19-30. 1931.—A study of the incidence, structure, and origin of cysts in the anterior palatine region of the maxilla and of the region itself revealed the inadequacy of our present terminology. Most of the difficulty will be obviated if we speak of major and minor anterior palatine canals; of a common anterior palatine canal; of an anterior palatine fossa and foramen, and of superior and inferior foramina of the major and minor anterior palatine canals. Excerpts from current and past anatomical literature are included in the discussion.—*Author (courtesy Wistar Bibl. Serv.).*

11317. **ODGERS, P. N. B. Two details about the neck of the femur: (1) the eminentia, (2) the empreinte.** *Jour. Anat.* 65(3): 352-362. 2 pl. 1931.—The material studied consists of 52 prs. of fresh femurs of known age and sex. The eminentia articularis colli femoris is a ridge of bone, which runs from the superior tubercle of the intertrochanteric line to the head of the femur; it is much better marked in ♂ than in ♀ bones and is not seen in the anthropoids. In over ¼ of ♂ femurs its medial portion is covered by fibrocartilage, which extends onto it from the articular margin. The eminence

acts as a pulley bar for the anterior portion of the capsule in extension of the hip joint. The empreinte of Poirier or the cervical fossa of Allen commences as a depression on the medial end of this eminentia: as this deepens, the fibrocartilage is destroyed and the bone is eroded. It is more often seen in ♂ than in ♀ bones, and, with some exceptions, the older the individual, the deeper will be the empreinte. The circular fibers of the hip-joint capsule—the zona orbicularis—are well marked anteriorly. These are in contact with the medial end of the eminence and are responsible for the appearance of a depression or an erosion in this situation.—*Author's summary.*

11318. **SACERDOTE, G., e G. OSELLADORE. Modificazioni circolatorie provocate nelle epifisi dall'impianto di caviglie ossee. [Circulatory changes produced in the epiphyses by implantation of bone pegs.]** *Arch. Ital. Chir.* 28(6): 648-655. 4 fig. 1931.—In dogs, implantation of bone pegs in the femoral and tibial epiphyses produced an increase in the vascular web (often an increase also in the caliber of the vessels) which attained its maximum 2-3 weeks after the operation, but was still manifest after 3 mos.

11319. **YAMASHITA, KENJI. Über die Schläfenbeinzellen. I. Die Porosität des mazerierten Schläfenbeins.** *Folia Anat. Japonica* 9(3/4): 311-314. 1 fig. 1931. —The author has studied the porosity of macerated temporal bone by a method of estimation of specific gravity, 23.24%-46.88%. The porosity in various parts of the temporal bone is: in the apex of petrous bone, 56.05%; the inner ear and its surrounding, 23.96%; the antrum mastoideum and its surrounding, 50.29%; the outer side of the mastoid process, 38.31%; the zygomatic arch, 24.28%; the posterior portion of the sinus sigmoideus, 20.53%; and the squamous portion, 10.24%. —*Author (courtesy Wistar Bibl. Serv.).*

ADENOID TISSUE

11320. **FÉRESTER, M. Sur la greffe des ganglions lymphatiques.** *Compt. Rend. Soc. Biol.* 106(10): 789-791. 1931.—In 48 guinea pigs 1½-3 mos. old, the small lymph nodes from the hyoid region were transplanted, either wholly or in fragments, under the skin of the thigh or between the muscles of the abdominal wall; 100 grafts were examined. After a phase of necrosis during which the lymphocytes suffer especially, the graft, whether a whole node or a fragment, tends to reconstruct itself. Lymphocytes are formed in situ; the marginal sinus is rebuilt, and often the germinal centers, exactly like those found in the normal node, are formed.—*E. Weiner.*

11321. **KELEMEN, GEORG. Explantationsversuche mit Tonsillengewebe. IV. Beeinflussung des in vitro-Wachstums von Embryonalgeweben durch Tonsillensubstanz. [Effect of tonsil substance on the growth in vitro of embryonic tissue.]** *Acta Oto-Laryngol.* 15 (2/4): 199-209. 6 fig. 1931.—The tissues used (from 8-day chick embryos) were heart muscle and iris, the first because viability is verifiable through pulsation, the second because the migrating chromatophore cells are easily observed. The 4 series were: (1) heart + autogenous plasma: (2) heart + plasma + tonsil extract; (3) iris + plasma; (4) iris + plasma + tonsil extract. Each series comprised 60 cultures, and the whole group of experiments was carried out 4 times; altogether more than 1,100 cultures were used. The tonsil extract either prevented the growth of fibrocytes or reduced it to a minimum, an action coinciding with that of another organ belonging to the reticulo-endothelial system, the liver, and contrasting with that of leucocyte extract. Addition of embryonic extract often decreased this growth-inhibiting action but did not neutralize it.

11322. **SHIMIZU, SADAO. Sur le ganglion cystique.** *Folia Anat. Japonica* 9(2): 79-80. 1931.—The author made statistical observations on the lymph node on the cystic duct which is reported to swell and indurate in acute or chronic diseases of the bile tract. The afferentia of this gland were also studied. Observations made on 50 cadavers of Japanese (37 fetuses, 2 infants, 3 children, and 8 adults) showed: (1) The gland is situated on the first section of the cystic duct. (2) There is never more than 1 gland and its length in adults is about 1 cm. (3) No gland was found in 3 out of the 50 cases examined (6%). (4) The gland collects most of the lymph from the gall bladder.—*Author (courtesy Wistar Bibl. Serv.).*

11323. **TEITEL-BERNARD, ALFRED. Über die Blutzirkulation in der Hundemilz.** *Zeitschr. Wiss. Biol. Abt. B, Zeitschr. Zellforsch. u. Mikrosk. Anat.* 12(3): 544-558. 13 fig. 1931.—Specimens were removed from spleens (in various conditions of filling or emptying according to the action of epinephrine, choline, pilocarpine, atropine, and insulin) of anesthetized dogs and from an anesthetized control, fixed, and stained (Regaud's Fe hematoxylin, Azan, Giemsa, hematoxylin-eosin-orange, or Perl's Fe reaction) in 3, 4, and 6μ serial sections; intra-arterial injections with ink were also made. Schweigger-Seidel's cortex had a spongy structure and was intimately related to the venous capillaries. The red blood cells left the arterial route through the spaces and canals of this cortex and passed into the pulp, mainly into the venous capillaries. At the point of passage the red blood cells lost a part of their body in the interior of the arteries as "hematic granules" which remained attached to the arterial wall. By special staining methods numerous erythrocytes which had passed from the pulp into the venous capillaries were found, most frequently in the contracted spleen. At these points of passage, too, the erythrocytes deposited hematic granules, this time outside the vessel. The club shaped ends of the pulp arteries, designated as end chambers, are only the cortex itself impregnated by the injection.

PHYSICAL ANTHROPOLOGY

11324. **ADACHI, SH. Über die Form Parotis der Wilden in Formosa.** *Taiwan Igakki Zasshi [Jour. Med. Assoc. Formosa]* 30(1) (no. 310): 1-3. 1931.—In 21 parotids from 12 individuals, the shape did not differ from that of other races, but the capacity (av. 17.5 cc.) was greater than that of Europeans and Japanese. Detailed measurements are given for the several topographic and anatomic parts of the organ and its duct.—*E. C. Faust.*

11325. **ALLIOT, H. Présentation de deux jumeaux bivitellins.** *Bull. Soc. Étude Formes Hum.* 6(1/2): 188-191. 1928.—The author presents description and photographs (front, back, profile) of a boy and girl of 16 yrs., twins but apparently 4 or 5 yrs. apart. Measurements: for the girl, height 153.5 cm., chest circumference 73-76 cm., weight 51 kilos; for the boy, height 136.5 cm., chest 66-68.5 cm., weight 30 kilos. The girl conformed to the usual muscular type. The boy (less than half his sister's weight at birth) had feeble musculature, was physically underdeveloped in every way, and was mentally much below his age. Several cases of twin pregnancy had previously occurred in their mother's family. —*H. Alliot (transl. by J. B. Bullitt).*

11326. **ARNOLD, A. Ein Beitrag zur Anthropologie der deutschen Frau und zur Frage der Einwirkung planmässiger Leibesübungen auf den weiblichen Körper.** *Zeitschr. Ges. Anat. Abt. 2, Zeitschr. Konstitutionsl.* 15(5): 651-663. 1930.—Detailed measurements on 25 women, aged 21, before and after a course of gymnastic training showed that a portion of the subcutaneous fatty tissue was lost; the musculature of the extremities was not greatly affected. Thus the rounded form frequently designated as sexual differentiation can be changed into the more slender type.

11327. **ASHLEY-MONTAGU, FRANCIS M. On the primate thumb.** *Amer. Jour. Phys. Anthrop.* 15(2): 291-314. 1931.—185 hands of 185 *Primates* were measured to determine the relative length of the thumb in the various groups. This number was insufficient to provide a reliable index of the average relative length of the thumb in the groups examined. The figures obtained, however, were sufficient to indicate that the functionally

tailless lorises possess the highest pollical index, man the next highest, then the lemurs, New-World monkeys, Old-World monkeys, and, finally, the anthropoids. Differences in the index were found to exist between the races of man. The evolution of the opposable thumb seems to be correlated with the decline in the functions of the tail. The short thumb seems to be produced by an overspecialized arboreal life. The terrestrial *Primates* possess long thumbs. The thumb of the anthropoids would appear to have undergone a reduction since their divergence with man from the common ancestral stocks; that of man, an elongation. In the terrestrial gorilla the thumb has undergone a secondary elongation consequent upon its adaptation to the demands of terrestrial life. With few exceptions, the tendency of the thumb is to increase in length with age.—*Author (courtesy Wistar Bibl. Serv.).*

11328. **BAEYER, H. von. Der lebendige Arm.** [The living arm.] 46p. 15 pl. Gustav Fischer: Jena, 1930.

11329. **BARBOSA SUEIRO, M. B. Anotações anatômicas. VII. Segunda nota sôbre a apôfise supra-epitroclear (processus supracondyloideus, BNA).** [VII. Second note on the supra-epitrochlear apophysis (processus supracondyloideus, BNA.).] *Arquivo Anat. e Antrop* [*Lisboa*] 13(1/2): 143-156. 2 fig. 1929(1930).—A report of 3 cases of the occurrence of the apophysis. In 1 case, a ♀, the apophysis was unilateral, in the left arm, and there was an anastomotic vas aberrans extending from the brachial to the ulnar artery and passing through the osteo-fibrous arch together with the median nerve. In a living man, 47 yrs. of age, the apophysis was bilateral and was demonstrated both by palpation and by radiography. A diagnosis of the apophysis may be important in ligation of the brachial artery and it may be mistaken for an enlarged supra-epitrochlear node. It may be recognized with certainty by radiography. The records are at present insufficient for determining whether it is more frequent in the insane and criminal than in normal persons. It is a congenital structure, inheritable and atavistic.—*M. B. Barbosa Sueiro (transl. by J. P. McMurrich).*

11330. **BASLER, ADOLF. Der Schwerpunkt der lebenden Menschen. Schwerpunktwage und Schwerpunktpendel.** 100p. 45 fig. Sun Yatsen-Universitaet: Canton, 1931.—A treatise of the history and technique of the determination of the center of gravity of the human body. The historical part is followed by an extensive consideration of the gravity line in the standing, horizontal, and squatting positions. This center of gravity is constantly changing in the living, breathing and pulsating body. Variations in the activity of different muscle groups affect the curve of horizontal movements of the gravity point. Further are discussed the results of measuring precisely the vertical distance of the center of gravity from the sole of the foot. The author suggests new and more delicate apparatus for getting the height of the point of gravity. Chiefly Chinese subjects have been used.—*C. B. Davenport.*

11331. **BLOCH, ADOLPHE. Sur le physique des indigènes de Taiti, lors de la découverte de l'île, et ce que nous croyons de leur origine.** *Bull. Soc. Anthrop. Paris* 8(4/6): 211-216. 1927.—The author gives a brief verbatim account from the works of the first explorers of Tahiti, of the physical characteristics of the natives (Wallis 1767, Bougainville 1768, Cook 1769, Forster 1772, Lesson 1822, and the resident physician Gros). These accounts concur in the observation of characteristics ascribable to the Melanesian and Caucasian races with the probable priority of the former, the latter being distinguished by blond and even red hairs and a lighter pigmentation, while nose, lips and mouth are large. They also differ in stature, although representing on the whole tall human varieties with individuals attaining even 194 cm.—*B. Oetteking.*

11332. **BONIN, GERHARDT von. Der Koeffizient der Rassenähnlichkeit und seine Anwendung am Lebenden.** *Anthrop. Anz.* 7(1/2): 82-102. Map. 1930.—Explains the mathematical deduction leading up to the usual form of the "Coefficient of Racial Likeness" (C. R. L.) given by Karl Pearson. The method is applied to the material provided by Alette Schreiner from Northern Norway, by Roth-Lutra from the Palatinate, and by Hannesson from Iceland. The biometric constants of these series are discussed and their racial affinities determined by the C. R. L. They agree closely with those arrived at by other methods.—*G. v. Bonin.*

11333. **BOYD, EDITH, RICHARD E. SCAMMON, and DONOVAN LAWRENCE. The determination of surface area of living children.** *Proc. Soc. Exp. Biol. & Med.* 27(5): 445-449. 2 fig. 1930.—A plaster of Paris cast of the body is made and covered with adhesive tape. The tape is stripped off, cut into flat pieces and the outline of each piece was traced with a knife on "Kodaloid No. 3"; the area of the pieces of Kodaloid was determined by weighing. This process gives body surface area with an error of only about 2%.

11334. **BRINK, VERNON H. A comparative study on the sacrum of the Griqua.** *Trans. Roy. Soc. So. Africa* 18(4): 287-293. 1930.—The Griqua were a people, now virtually become extinct by further intermarriage, whose ancestors were of widely divergent anthropological character. Certain features of the sacra here reported seem to illustrate this fact. There is considerable numerical variation in the sacral segments, and sacra grouped on this basis showed features closely comparable with those already found by Wetzel in Australian sacra similarly classified. On the whole no one type of numerical abnormality could be said to accompany other sacral characteristics which were clearly of more primitive type than those of normal Griqua sacra. On empirical measurements, the Griqua sacrum approximated fairly closely to the European and more particularly to the Bantu (especially the Griqua ♀)—yet in proportions the sacrum of the Griqua was reminiscent far more of sacra of Bush and Hottentot. As only 14 sacra in all were reported upon, conclusions are unjustifiable, but the following suggestions emerge:—(1) The high numerical variability in Griqua sacra is eloquent of the hybrid parentage of the people. (2) Certain features, e.g., length and breadth of the sacra, can be interpreted as being marks of Bantu and European blood—others which obviously are not, but which Bushman blood would conveniently explain, e.g., shallowness of the sacrum. (3) Classification of the sacra according to numerical variations in the vertebral column as a whole seems logical and suitable.—*V. H. Brink.*

11335. **BRYN, HALFDAN. Der nordische Mensch. Die Merkmale der nordischen Rasse mit besonderer Berücksichtigung der rassischen Verhältnisse Norwegens.** 166p. 10 maps. 126 fig. J. F. Lehmann: München, 1929. Pr. 9 M.—A summary of the developmental characters of Nordic man—blondness and tall stature. An account of Scandinavia and its relation to the ice age, the retreat of the glacier and immigration into it as source of Nordic people. The percentage of blue eyes is given in different sections of Norway and of Europe. The distribution of body size and head index throughout Norway is given and the relation of these features to pigmentation is discussed. A chapter is devoted to individual characters in the Nordic race, including form of nose, bridge and tip from frontal, lateral and caudal aspects. The pinna and other characters are also treated. Sections are devoted to the intellectual characters of the Nordic race and to Nordic women. The presence of brachycephalic blondes is also discussed and the osteological characters of Nordic men are considered. A bibliography of 112 items is added, the books cited being largely in the Norwegian language. The book is abundantly illustrated with maps and portraits.—*C. B. Davenport.*

11336. **BRYN, HALFDAN. Die blonden Brachykephalen in Norwegen.** *Anthrop. Anz.* 6(3): 231-248. 1 fig. 1930.—Author discusses the various opinions regarding the status of blond brachycephals. These are to be found everywhere in Norway. Where few in number they are homogeneous and may be taken for a variety of Nordic.

But in some regions they are quite unlike the Nordics. The author investigated the population of Jaeren, southwest Norway, where a relatively dark-haired, dark-eyed and dark-skinned type prevails which has been called the "Jaeren type." He notes a high correlation between darker hair and brachycephaly which bespeaks interdependence of the two. The evidence indicates a crossing between a blond dolichocephalic and a dark brachycephalic race. They have the general features of the Alpine race as Ripley first suggested. They do not, however, represent an independent race but a mixture of Alpine and Nordic. They are dark only in a relative sense, when compared to the other elements of Norway. They may be classified as blonds; hence the designation blond brachycephals.—*C. J. Connolly.*

11337. [BUNAK, V. V.] БУНАК, В. В. Черепа железного века из севанского района Армении. [Iron age skulls from the Sevan District (Armenia).] [English summary.] Русский Антропологический Журнал (*Jour. Russe Anthrop.*) 17(3/4): 64-87. 1929.—The skulls described are dolichocranic, chame-orthocranic, leptoprosopic, leptorhinic and mesoconchic. Their type is definitely European. They show much closer resemblance to Swedish Iron age skulls than to Minoan age skulls of Crete. This fact furnished a craniological confirmation for the theory of the migration of the North European type to the south during prehistoric times.—*V. V. Bunak.*

11338. **CAVE, A. J. E. The craniopharyngeal canal in man and anthropoids.** *Jour. Anat.* 65(3): 363-367. 4 fig. 1931.—Report of a case in man and of findings in 56 chimpanzees (found 36 times), 57 gorillas (20), 44 orangs (6), and 26 lower primates (6). The author concludes that neither age nor sex has any direct bearing upon the incidence or the features of the canal, which is much commoner in the orang than in man, 3 times more common in the gorilla, and commoner still in the chimpanzee.

11339. [CHISTĬAKOV, G. A.] ЧИСТЯКОВ, Г. А. К вопросу о корреляциях размеров тела. [Correlations between bodily dimensions.] [French résumé.] Материалы по Антропологии Украины (*Anthrop. Ukraine*) 3: 98-111. 1927.—The author presents measurements of 504 Ukrainian peasants, aged 23, from Kharkov and Soumy. Tables show coefficients of correlation between stature and various dimensions and indices; these are arranged according to Pearson's classification (1-.75 high, .75-.50 considerable, .50-.25 moderate, .25-0 low). Some of these correlations are as follows: Stature to sitting height = .73, to length of trunk = .57, to spread of arms = .77, to length of upper extremity = .68, to length of lower extremity = .84, to size of pelvis = .52. Length of upper extremity to length of arm = .76, to length of forearm = .65, to length of hand = .60. Length of upper extremity to length of lower extremity = .75. Length of lower extremity to length of thigh = .78, to length of leg = .72, to length of foot = .62. Height of forehead to length of face = .70. Only moderate correlation exists between stature and head dimensions (.25-.35), between length and diameters of the trunk (.25-.45), and between length of trunk and length of extremities. Practically no correlation exists between stature and cephalic index, between length of trunk and thoracic index, between length and circumference of extremities, length and breadth of face, length of face and breadth of nose or mouth. The author believes that study of the degree of interdependence of bodily dimensions in various ethnic groups may reveal anthropological differences. —*J. B. Bullitt.*

11340. **CLARK, GRACE. A method of computing the cross-section of the chest for children at seven, eight, and nine years.** *Human Biol.* 2(4): 539-546. 1930.—An empirical formula for finding the area of a transverse segment of the chest was derived from 3 measurements: width, depth, and circumference. By means of lead taps the shape of the chest in 7-, 8-, and 9-yr.-old children was found to resemble a parallel octagon. The measurements of the chest were then substituted in the empirical formula for this figure, and the results were compared with the true area derived by measuring the area of the traced shape with a Coradi disc planimeter. —*G. Clark.*

11341. **CLEMENTS, FORREST. Racial differences in color-blindness.** *Amer. Jour. Physical Anthrop.* 14(3): 417-432. 1930.—A review of the conclusions reached by the philological researches of Geiger, Magnus, and Rivers indicates that differences in color terminology may be connected with differences in color vision. Inspection of earlier work on color-blindness among primitive peoples shows that, even when these results are discounted on the basis of faulty technique, imperfect tests, and errors of sampling, there remains enough evidence to lend weight to the assumption of racial differences. It is believed that the Ishihara test for color-blindness is a good diagnostic instrument for most practical work. This test gave an incidence of 8.0% among 3734 white ♂♂ and 0.43% among 3000 white ♀♀. The percentage among 624 American Indian ♂♂ was 1.9%, and no case occurred among 200 Indian ♀♀. The same test gave an occurrence of 3.7% among 323 American negro ♂♂. Taken in connection with the earlier work, these results leave little doubt that racial differences in color-blindness do exist.—*Author (courtesy Wistar Bibl. Serv.).*

11342. **COLE, FAY-COOPER. Recent trends in anthropology.** *Proc. Amer. Philosoph. Soc.* 69(6): 385-390. 1930.

11343. **COUPIN, F. La croissance chez les anthropoides et chez l'homme.** *Rev. Scientifique* 66(23): 726-732. 6 fig. 1928.—After having reviewed classical conceptions of growth of stature and weight in man, and having expounded some new ideas (level of curves for weight and height, interruption of growth, difference in growth of the various parts of the body), the author gives hitherto unpublished figures, especially of a new-born chimpanzee and 2 young gorillas the age of which is known almost exactly (♀ 2 yrs. and 5 mos.; ♂ 3 yrs. and 1 mo.). Two provisional conclusions are to be drawn: (1) man is born relatively heavier than chimpanzee (1/22 instead of 1/45); (2) during early infancy man grows more rapidly than the anthropoids, except for the brain, which attains its ultimate weight sooner in anthropoids than in man. The adult proportions do not seem to be gained at corresponding stages by anthropoids and man; the former reach their final proportions much sooner. In the fetus of gibbon, for instance, the arms are relatively as long as those of the adult gibbon (Schultz). The brain also is an exception, as in man it reaches its final form earlier. These few facts do not permit confirmation of the thesis put forth by Bolk, of fetalization of human morphogenesis, or that of Reicher, who considers the anthropoids older than man, since they reach their final proportions earlier. The author indicates the importance of a large number of figures for anthropoids and appeals for the collaboration of all who are studying them. —*F. Coupin (transl. by B. Bickel).*

11344. **CUMMINS, HAROLD. Dermatoglyphics in Indians of southern Mexico and Central America.** *Amer. Jour. Physical Anthrop.* 15(1): 123-136. 1930.—Palmar main lines, palmar patterns, apical finger patterns, and the configurations of the 4 distal plantar areas are analyzed in 37 Indians of southern Mexico (Chiapas) and Central America (Guatemala, San Andres Peten). Racially significant trends of variation are as follows, the figures being percentile and stating the averages of the occurrences in right and left members: proximal terminations of line A (positions 1 and 2) are frequent (25); line B terminates commonly (88) in the ulnar border positions, 4, 5′, and 5″; line D terminates most frequently in position 9 (56) and in position 7 (28); the most common main-line formulae are 9.7.5—(49) and 7.5.5—(29); palmar hypothenar patterns very rare (5); thenar/first interdigital patterns exceptionally common (49); second interdigital patterns wanting; third interdigital patterns infrequent (16); fourth interdigital patterns very abundant (77); among apical patterns

whorls are abundant (42), and on digit I they are approximately equally represented in right and left hands; digit II reverses the typical bimanual distribution of radial loops, these patterns being here more abundant in left hands (possibly of no significance, in view of the rarity of the pattern and the small size of the collection); the A type of hallucal pattern is most common (74), and in the plantar interdigital areas the characteristic configurations (in tibiofibular order) are O (76), U (70), O (84).—*Author (courtesy Wistar Bibl. Serv.)*.

11345. **DAVENPORT, C. B., and BLANCHE M. MINOGUE. The intelligence quotient and the physical quotient; their fluctuation and intercorrelation.** *Human Biol.* 2(4): 473-507. 1930.—After a lengthy historical review indicating present state of our knowledge of the subject, the authors present the results of their study of physical and intellectual changes of 78 boys (5-20 yrs. old) at Letchworth Village for the Feeble-Minded, measured repeatedly during 5 or 6 yrs. The mental measurement was by the Terman revision of the Binet-Simon test. The physical measurement was based on a combination of departures from standards, for age, of tooth dehiscence, tooth eruption, development of permanent pubic and axillary hair, vertex height, relative span, relative sitting height, increments in total body weight. The physical quotient is that derived by dividing average physical age of the boy by his chronological age. The correlation between mental age and physical age thus determined increases from 0.24 at 9th yr. to 0.48 at 13th yr. The coefficient of correlation between the physical quotient and intelligence quotient also increases from 0.29 in 1924 to 0.49 (for about the same boys) in 1928. It appears, then, that the correlation between physical and mental development is about the same as correlation in stature between 2 brothers, namely, under the best of conditions about 0.50. The IQ tends in these feeble-minded boys to decrease with age. The physical quotient also decreases with age, but less than the IQ.—*C. B. Davenport.*

11346. **DONICI, ALEX. Note sur quelques crânes Scythes.** *Rev. Anthrop.* [*Paris*] 40(7/9): 233-236. 1930.—7 skulls found in Bessarabia show 2 entirely different human types. The 5 ♂ skulls are dolichocephalic and leptoprosopic, and the 2 ♀ skulls are brachycephalic and chamaeprosopic. Like the neolithic skulls of the same region they are extremely different from those of the actual inhabitants.—*A. Donici.*

11347. **DUNCAN, GEORGE S. Prehistoric man. An introduction to anthropology.** 143p. Stratford Co.: Boston, 1931. Pr. $1.50.—The book gives a brief description of the universe and earth; remains, origin and birthplace of man; the condition and religion of prehistoric man. —*K. S. Chouke.*

11348. **FISCHER, MAX. Die Formung der menschlichen Nase in der Pubertät.** *Arch. Frauenkrankh.* 16(2): 113-117. 1930.—General observation indicates that during puberty the soft parts of the nose undergo changes in size and shape which are not proportional to those elsewhere in the body. Systematic investigations may show this to be a secondary sex characteristic.

11349. **FRASSETTO, FABIO. Standardisation des méthodes anthropologiques. I. Nouveau procédé d'ajustement pour sériations binomiales symétriques.** *Rev. Anthrop.* [*Paris*] 40(7/9): 221-228. 3 fig. 1930.—The author explains elsewhere (See B. A. 4(4): Entry 10859) his procedure for the standardization of data which follows the binomial curve in distribution, and proposes here a new type of apt adjustment to render comparable all symmetrical or nearly symmetrical binomial curves, obtained without regard to the method of assembling the data, when the total area is equal to 100 cm.^{2} This new type of adjustment, which reduces to a minimum the use of calculations, consists essentially in replacing the empiric curve by a more regular curve, of which the frequency is calculated in a table. The same adjustment permits the easy classification (senary and trinary) and the bisexual deviation of characters without the aid of calculations.—*F. Frassetto (transl. by R. B. Bean).*

11350. **GEORGE, RUGGLES. Human finger types.** *Anat. Rec.* 46(2): 199-204. 1 fig. 1930.—An examination of 620 hands of white adults shows that in ♂♂ the ring finger is generally longer than the index finger. In ♀♀ the reverse is found. This is so both for the right hand and for the left hand.—*Author (courtesy Wistar Bibl. Serv.).*

11351. **GEYER, EBERHARD. Das frühbronzezeitliche Reihengräberfeld bei Mainburg-Teichtal. IV. Die anthropologischen Funde.** *Mitteil. Anthrop. Ges. Wien* 60(2/3): 98-140. 22 fig. 1930.—Skeletons of individuals of the Wieselburg culture are as yet almost unknown. Among the 13 reported in this paper 4 are definitely short headed. Of these 2 are hyperbrachycranial with high, sharp profiles, and 2 are brachycranial with lower and flat profiles. The first 2 may be identified as beaker-makers of the late stone or early bronze age, the second as related to East European or mongoloid skulls. The remaining, meso- and dolichocranial skulls are varied, but different from those of the neighboring station in Stillfried.—*E. Geyer (transl. by C. H. Danforth).*

11352. **GREGORY, WILLIAM K. Reply to Professor Wood-Jones's note: "Man and the anthropoids."** *Amer. Jour. Phys. Anthrop.* 12(2): 253-256. 2 fig. 1928.—The author reaffirms his acceptance of Wood-Jones's view that the alisphenoidparietal articulation at the pterion and the mesethmoid-presphenoid articulation in the anterior fossa are characteristic of adult modern man and that the opposite conditions are frequently found in adult apes. He continues, however, to dissent from Wood-Jones's evaluations of these facts in their bearing on the phylogeny of man. He calls attention to the variability of these contacts in the anthropoids as a whole and reaffirms that young gorilla and chimpanzee skulls examined by him retain the mesethmoid-presphenoid articulation as a narrow isthmus underneath the down-growing and overlapping processes from the frontal. Wood-Jones objects that the skull of the human child figured by Gregory does not represent the normal conditions of the presphenoid-mesethmoid articulation, since it shows small descending processes from the frontals which appear to meet in the midline. He therefore reproaches Gregory for not warning the reader that this is not a normal condition. The author's answer to this is that the illustration abundantly shows all that was claimed for it in the text, namely, the fundamental identity in plan between young gorilla and human skulls, in the aspect figured by him, in spite of admitted differences in details.—*Author (courtesy Wistar Bibl. Serv.).*

11353. **HESCH, M. Die Photographie in der Anthropologie. In: Photographisches Praktikum für Mediziner und Naturwissenschaftler,** edited by **A. HAY.** pp. 114-147. Springer: Wien, 1930.

11354. **HRDLIČKA, ALEŠ. Anthropological work on the Kuskokwim River, Alaska.** *Smithsonian Inst., Explorations and Field Work of the Smithsonian Inst. in 1930.* Publ. 3111. 123-134. 6 pl. 1931.—Studies on skeletons of Eskimos of the period before the Russian occupation showed a body form and cranial dimensions about the same as those today. Fractures were rare, indicating scarcity of warfare and violent sports; traces of tuberculosis, cancer, tumors, inflammation, syphilis, rachitis, and scurvy were not found. Various types of arthritis were found.

11355. [IVANOV, K. N.] ИВАНОВ, К. Н. **Размеры головы и рост студентов в зависимости от их социального происхождения и в связи с вопросом о корреляции величины мозгового отдела и интеллектуальных способностей. [Dimensions of head and growth of students in relation to their social descent and in connection with correlation of the size of the brain and intellectual abilities.]** [French résumé.] Материалы по Антропологии Украины (*Anthrop. Ukraine*) 3: 163-186. 1927.—The author completes the findings of his

preceding article by a study of the measurements of 1745 Kharkov students from 1887-1904, whose social origin differed considerably from that of the present day students. These include 259 Ukrainians, 380 Russians, 129 mixed Ukrainian-Russian, 770 Jews, 57 Georgians, 79 Armenians, 71 Poles. Social classification: peasants, artisans, merchants, priests, intellectuals. Tables give length, breadth, circumference of head, cephalic index and stature. Ukrainians show greater head length and circumference than Jews, but less than Russians. Ukrainians had the broadest heads, Armenians the shortest. Ukrainians were the tallest, Jews the shortest. Students were taller than peasants and artisans of the same nationality. Differences in relation to the social status of their parents were insignificant and uncorrelated, perhaps because most individuals examined came from the leisure classes. In spite of the difference in social distribution of students of the past and of the present, the measurements of the 2 groups are nearly the same.—*J. B. Bullitt.*

11356. [IVANOV, K. N.] ИВАНОВ, К. Н. Некоторые данные о размерах головы и о росте студентов медицинского факультета Харьковского университета, исследованных в периоде 1887-1904 г. г. [**Size of head and growth of students in the Medical Faculty of the Kharkov University, in the period of 1887-1904.**] [French résumé.] Материалы по Антропологии Украины (*Anthrop. Ukraine*) 3: 187-197. 1927.—In a recent study Nicolaeff finds that the dimensions of the heads of 507 Russian, Ukrainian and Jewish students exceed those of other individuals of corresponding age, race and social status. This points to a correlation between head size and intellectual capacity, but it might be questioned whether the real relation is merely a larger head on a larger body. The present author studies Nicolaeff's material and adds data on 534 similar students, a total of 1041, of whom 80.97% were 21-25 yrs. old. Social classification: peasants, artisans, intellectuals. In each of the social classes students show higher averages for general stature, for circumference, height and breadth of head and for height of forehead than do other persons of the same class and age. The differences, which are beyond the range of probable error, are most marked among peasants, least marked among intellectuals. Russians have larger heads, with lower cephalic index, than Ukrainians, but among both the index diminishes with social elevation. Extensive tables and graphs show detailed comparisons. Careful calculations show that in each social class of each racial group the larger head dimensions of students as compared with others of the same class is proportionately greater than their increased stature. The reverse should be true if the larger heads were merely accompaniments of larger bodies. This indicates a real correlation between cranial size and intellectual ability.—*J. B. Bullitt.*

11357. **KLEIN, ALBERT D., and RICHARD E. SCAMMON. Relations between surface area, weight and length of the human body in prenatal life.** *Proc. Soc. Exp. Biol. & Med.* 27(5): 456-461. 1930.—Surface area of the body was determined in 12 fetuses ranging from 2.68 to 31.98 cm. C. R. length and from 1.26 to 2463. gm. in weight, using, with slight modifications, the technique described by Boyd, Scammon, and Lawrence (Proc. Soc. Exp. Biol. & Med. 27(5): 445-449. 1930), and substituting the data into the formula which expresses the relation of surface area (S), to length (L), $S=aL^b$, or $\log S=\log a+\log L\cdot b$ where a and b are constants, b being close to 2; to determine the value of these constants. The following values were obtained: with data for crown-heel length, the values of a and b are, respectively: for crown-heel length, 0.2808 and 2.278; and for crown-rump length, 0.4545 and 2.401. The theoretical relationship of surface to weight is: $S=aW^b$, or $\log S=\log a+\log W\cdot B$. [$W$ being in gms.] The values of a and b, from the data obtained, are: $a=5.188$; $b=0.55$.

11358. **SCAMMON, RICHARD E., and ALBERT D. KLEIN. Surface area and age in prenatal life.** *Proc. Soc. Exp. Biol. & Med.* 27(5): 461-463. 1930.—For 12 fetuses [reported on by Klein and Scammon, see preceding abstract] ranging from 2.68 to 31.98 cm. in C. R. length and from 1.26 to 2463 gm. in weight, the surface area was related to the age of the fetus (expressed in lunar months after the last menstruation). Data are given.

11359. **KLIMEK, STANISŁAW. Przyczynek do kranjologji Indjan amerykańskich. [Craniology of the American Indians.]** [German summary.] *Kosmos [Lwów]* 53(4): 809-829. 1928(1929).—After a review of Siemiradzki's summary of the anthropological affinities of American aborigines, the results of an analysis of the 22 skulls of Virchow's publication are presented. In spite of the paucity of material the series should give a fair view of the typical craniological forms of the primitive American peoples since the skulls were selected by Virchow from a large amount of material. Special methods devised by Czekanowski were used, involving differential diagnoses and a method for determining similarity. The statistical analysis substantiates perfectly the views of Siemiradzki. The following 4 elements were distinguished: (1) the Lapponoid type, a variant of the central Asiatic race which is identical with the Tupi-Guarini types; (2) Paleo-American type, identical with the Mongoloid type; (3) the arctic type, identical with the Eskimoid type; and (4) the Pacific type, identical with the Caribbean type. The Mountain type could not be distinguished. This is not surprising since this type is similar to the Caribbean race in head and facial features. All of the above types are of Asiatic origin. The Lapponoid type forms the anthropological basis for the central Asiatic Mongolian and Turkish races; the Pacific type forms the basis for the inhabitants of North China, Manchuria, and Korea; the Arctic type is recognizable in numerous traces in North and Middle Asia; the Paleo-American type, however, has not yet been discovered in Asiatic material. It may undoubtedly be considered as a branch of the yellow race. The above classification approaches the Cuvierian system. Whether other Asiatic elements may be present in the American primitive populations can be answered only after a more comprehensive study of further material.—*From author's summary (transl. by P. Okkelberg).*

11360. **KROGMAN, W. M. Studies in growth changes in the skull and face of anthropoids. I. The eruption of the teeth in anthropoids and Old World apes. II. Ectocranial and endocranial suture closure in anthropoids and Old World apes.** *Amer. Jour. Anat.* 46(2): 303-313; 315-353. 1930.—I. The sequence and rate of the eruption of the teeth have been studied in the skulls of 707 anthropoids and Old-World apes. The deciduous teeth, completely erupted, according to Keith, by the end of the 2nd year in the anthropoids, erupt, variably, in the order of central and lateral incisors, 1st and 2nd molars, and canine. The 1st molar is the first permanent tooth to erupt, presumably at or shortly before the age of 4 yrs. There follows a period of even growth followed by eruption (possibly at 5 or 6 yrs.) of central and lateral incisors, premolars, and 2nd molars in rapid succession. The premolars and 2nd molars tend to erupt together, premolars first in *Gorilla* and *Pithecus;* 2nd molars first in *Pan, Pongo, Hylobates,* and *Papio.* After an interval, the 3rd molar and canine erupt. The canine has the longest eruptive period of the permanent teeth. There is a tendency, in ♂ anthropoids, for the 3rd molar to compete its eruption first. This constitutes the sole observed sex difference in tooth eruption. A study, in both anthropoids and man, of the relation of epiphyseal union to the eruption of the teeth demonstrates fundamental similarity in growth pattern, with a tendency for the entire growth process in the anthropoids to be consummated in a much shorter period.—II. Ectocranial and endocranial suture closure was studied in detail in 707 skulls of anthropoids and Old-World apes. The sutures of the vault close first, with a tendency, except in *Pongo* and *Pan,* for the lamb-

doid to close earlier. The circummeatal sutures and the spheno-occipital close soon after the vault sutures. By the time of the eruption of the 3rd molar the cranium is almost completely united, the masto-occipital remaining patent until adult life. The sutures of the face close after an interval. The craniofacial sutures close last, exhibiting an instability in keeping with their function as "buffer" sutures between skull and face. There seems to be no sex difference in the closure pattern. The sequence and rate of endocranial suture closure are the same as those of ectocranial closure. There is a tendency, best exemplified in the coronal suture, for a reversal in direction of closure. A correlation of the unpublished Western Reserve University data upon epiphyseal union with the pattern of suture closure emphasizes the early and rapid closure of the sutures as contrasted with the human pattern. There is a transition from early complete cranial closure in the Old-World ape, through early vault closure in the Gibbon, and selective regional vault closure in the great anthropoids, culminating in relatively long-enduring patency of the lambdoid region in man.—*Author (courtesy Wistar Bibl. Serv.)*.

11361. **LAUENER, P. Normale Körperformen und einige Beziehungen zu den Leibesübungen.** *Körpererziehung [Bern]* 8(2): 33-38; (3): 72-75. 1930.—The forms of the body, which, of course, are not yet definitely marked in children, however strongly marked in the juvenile, are of importance in athletics. The qualification for the athletic activity differs according to the type of the body form (athletic, asthenic, pyknic and a medium type). Often the desire of a child for a certain sport already indicates the future form of his body. The choice of sports by a nation is influenced by its particular body form. Thus the differences in kinds and desires of sport in the various states.—*P. Lauener.*

11362. **LEIPOLD, HERMANN (foreword by Eugen Matthias). Körperbaustudien an den Wettkämpfern des bayrischen Turnfestes (Bamberg).** 53p. Otto Gmelin: München, 1928. Pr. 3.25 M.—The following measurements were recorded: body height and weight; length of trunk, leg and arm; girth of chest during ex- and inhalation, of leg and arm. The measurements furthermore occasioned proportional and correlational calculations, the results of which are condensed in special diagrams. It has been shown that the skeleton is functionally reactive, in such a way, however, that uninterrupted pressure causes retardation of osseous growth and even resorption of osseous matter, while pressure and relaxation in some sort of an alternating order increase osseous growth. Besides the general phenotypical effects of athletic practices it appears that the more genotypically selective qualities of body size and weight are, at least to some extent, likewise influenced by such practices, so that the differentiation into athletic types seems to be phenotypically and genotypically conditioned.—*B. Oetteking.*

11363. **LESTER, P. Contribution à l'anthropologie des Somalis.** *Bull. et Mém. Soc. Anthrop. Paris* 8(4/6): 175-188. 2 pl., 4 fig. 1927.—Quite in contrast with the more numerous somatological investigations upon the Somalis, the osteological and particularly the craniological investigations lag far behind. The number of crania recorded in literature, according to the author, is 28, of which 18 are ♂, 4 ♀ and 6 juvenile. This number is augmented by 5 adult ♂ crania recorded in the present paper. The study from the point of average revealed rather large capacities, dolichocrany, hypsicrany, a large forehead, meseny and prognathy, equal amounts of chamae- and hypsikonchy, and chamaerrhiny and mesorrhiny. The facial morphology suggested to the author the mixed racial conditions obtaining in the Somalis which, as previously Puccioni has done, could be distinguished as dolichohypsicranial, dolichochamaecranial and brachyhypsicranial, each, with their specific characteristics. The measurements of the 5 crania are collected in table 1, while table 2 contains the proportional measurements of 22 Somali crania from different authors including the 5 studied by the author.—*B. Oetteking.*

11364. **LI, JU-CHI. A study of variation and correlation in the physical measurements of Tsing Hua and Yenching students.** *Bull. Dept. Biol. Yenching Univ. [Peping]* 93-104. (Frequency and correlation tables p. 105-117). 1930.—It was found by the variation studies that the northerner is decidedly taller, thicker in chest capacity and heavier. On the other hand, the southern Chinese has a slightly longer leg in relation to the total height and has proportionally slightly wider shoulders. But on the whole, the northern type blends so imperceptibly with that of the south that it is hardly justifiable to separate them on geographical grounds except for the purpose of comparison as herein used. The results of the correlation studies show that there are varying degrees of interdependence between the different parts of the body, as for instance width is dependent upon height and girth upon width, etc.—*From author's summary.*

11365. **LORENTZ, F. H. Die Konstitutionsindices des wachsenden Menschenkörpers.** *Zeitschr. Ges. Anat. Abt. 2. Zeitschr. Konstitutionsl.* 14(6): 648-661. 1929.—Indices are based upon study of the average values of weight and height of 1,000,000 investigations taken from literature. The 4 new body indices (height expressed in cm., weight in kg. are: (1) Infantile index: birth-2½ yrs., height − weight + 65 − (height − 34) · 0.75 = 100. (2) Pre-school index: 2½-6 yrs., height − weight − (height − 123) · 0.7 = 100. (3) High school index: 6-14 yrs., height − weight − (height − 125) · 0.5 = 100. (4) Post-school index: 14-18 yrs., height − (weight − 10) = 100. Normal index is 100, index over 100 expresses underweight, under 100 expresses overwight. It is possible to compare children from birth to adult life and to study the effect of social differences, differences in feeding, occupation and body exercise, as well as racial differences. —*L. M. Hejinian.*

11366. **LOTH, EDWARD. C. I. R. P. Comité international des recherches sur les parties non osseuses (molles).** [In Polish and French.] *Folia Morphologica* 1(1): 9. 1929; [in German] *Zeitschr. Morph. u. Anthrop* 28(3): 360-374. 1930; the same in English by A. KEITH in *Jour. Anat.* 64: 99-103. 1929.—At the joint Congress of the Association des Anatomistes and the Anatomical Society of Great Britain and Ireland in 1927 there was established the "Comité international des recherches sur les parties non osseuses (molles)" for short called C. I. R. P. After some years this Committee has been organized as follows: president: Sir Arthur Keith (London); vice presidents; Anthony (Paris), E. Fischer (Berlin), Livini (Milano), Pires de Lima (Porto); secretary general: E. Loth (Warsaw). The Committee unites about 50 scientists from different parts of the world, with representatives of all medical schools of exotic countries. The Committee has published 3 questionnaires concerning the researches on living men, on cadavers, and on the methods of preservation and sending material to scientific laboratories. In addition, attempts are made to assure the collaboration of the Institut International de la Cooperation Intellectuelle, which is an institution of the Society of Nations. The first 4 works of the Committee have been already published. Other works are in preparation.—*E. Loth.*

11367. **MAHALANOBIS, P. C. A statistical study of certain anthropometric measurements from Sweden.** *Biometrika* 22(1/2): 94-108. 1930.—An analysis, by the coefficient of racial likeness, of measurements of 46,983 soldiers and sailors of 20-22 yrs., classified according to birthplace on 2 bases: (a) geographical, (b) occupational. Some characters—cephalic index, stature, suprasternal height—show markedly significant territorial differences but no occupational sequence within the territories; others—morphological, face height, bi-acromial index—show no territorial differences but a markedly significant occupational sequence within the territories; others are intermediate or unrelated to either variable. The Swedes are markedly homogeneous, but there has

been some mixture—strongest in the North—of East Baltic stock with the predominant Nordic type.—*J. R. Miner.*

11368. **MARINESCO, G., (with the collaboration of A. BRUCH, et G. BUTTU).** Recherches sur l'architecture des capillaires en rapport avec la constitution somato-psychique. *Bull. Acad. Méd.* [*Paris*] 103(22): 596-601. 1930.—Using Kretschmer's classification of constitutional types and the terminology of Jaensch and Hoepfner for the classification of capillary types, the author and his associates found, in 45 asthenics, 65.8% neocapillaries, 3.2% hypoplastic capillaries, 31.6% mesocapillaries; in 30 pyknics, 77.8% neocapillaries, 5.5% hypoplastic capillaries, 16.7% mesocapillaries; in 20 dysplastics, 11.1% hypoplastic capillaries, 11.1% mesocapillaries, and 77.8% archicapillaries; i.e., neocapillaries predominate in asthenics and pyknics, archicapillaries in dysplastics.

11369. **MOMMSEN, F.** Statischer Ausgleich von Fehlformen nach Untersuchungen am Biesalskischen Drei-Ebenen-Körpermessapparat. *Zeitschr. Orthrop. Chir.* 53(3): 344-366. 11 fig. 1930.—Description of an apparatus for measurement of the human body in 3 dimensions.

11370. **NAÑAGAS, JUAN C.** Contribution to the craniology of the Filipinos. II. On the cranial dimensions and indices. *Philippine Jour. Sci.* 42(3): 347-409. 1 pl. 1930.—This study is based on 461 crania of the low social and intellectual stratum of the Filipino race. Of these 438 are ♂♂ and 23 are ♀♀; 30% are within the ages of 26 and 35, and 35% are between 21 and 40 yrs. The mean antero-posterior diameter of the crania in the ♂ is 175.5 mm. and in the ♀ is 167 mm. The range of variation in this diameter is very limited. The mean transverse diameter is 146 mm. in the ♂ and 138 mm. in the ♀. This diameter is slightly more variable, absolutely and relatively, in the ♀ than in the ♂. The range of variation of this diameter is twice that found for the antero-posterior diameter. The mean length-breadth index is 84.8 in the ♂ and 82.5 in the ♀. This index shows more variability in ♂♂ than in ♀♀ of the race, absolutely and relatively. The greatest frequency of this index falls under the brachycephalic type. The mean basilo-bregmatic diameter is 140.5 mm. for the ♂ and 132 mm. for the ♀. The length-height index of this series of crania is 79.9 in the ♂ and 78.9 in the ♀. This index is more variable in the ♂ than in the ♀; its greatest frequency is found under the hypsicephalic type. The mean breadth-height indices for the ♂ and ♀ groups are 94.8 and 95.8 respectively. The highest frequency of this index is found under the metriocephalic classification. The mean sagittal arc of the Filipino crania in the ♂ is 370.2 mm. and in the ♀ is 369 mm. The mean transverse arc is 320.5 for the ♂ and 308.6 mm. for the ♀. The latter arc is more variable, absolutely and relatively, in the ♀ than in the ♂, a condition quite the reverse of that for the sagittal arc. The mean horizontal circumference of the crania is 505.3 mm. for the ♂ and 486.1 for the ♀; it is more variable in the ♀ than in the ♂ in this series. The mean auriculo-bregmatic heights in these skulls for the ♂ and ♀ cases are 115.5 mm. and 113.1 mm. respectively. The mean minimum frontal diameter is 95.4 mm. in the ♂ and 90.8 mm. in the ♀. The mean bimastoid diameters are respectively 122.5 mm. and 119.4 mm. Comparisons are made of these different diameters, circumferences and indices of the Filipino crania with those reported for the other Asiatic and Pacific Islands races. Some interesting findings were observed. Similar comparisons were followed between the findings and those of several European cranial measurements and the results are also presented in this paper.—*J. C. Nañagas.*

11371. **[NEDRIGAÎLOVA, O. V.]** НЕДРИГАЙЛОВА, О. В. Изменения физических признаков украинок при старении. **[Changes of physical characteristics in ageing Ukrainian women.]** [French résumé.] Материалы по Антропологии Украины (*Anthrop. Ukraine*) 3: 112-154. 9 fig. 1927.—The following indicators of age were studied in 198 Ukrainian working women 56-98 yrs. old.: white hair, abundance of hair, moustache and beard, eyes, mastication, skin, climacteric and menstruation, stature, thorax, size, cephalic index, and perimeters. Abundance of hair is a better index of age than whiteness; moustache occurred in 16.3%, and moustache and beard in 18.2%, with indications of masculinity in some. Eyes were deep in orbit, with arcus senilis, and yellow sclera. There was atrophy of the mechanism of mastication. Teeth were absent in 10.7% between 55-65 yrs., in 25.0% over 85. There was increased wear of teeth with age. Changes in skin were progressive: (1), fine lines at angle of eyes, transverse on forehead and vertical over glabella; (2) oculo-malar and mento-malar lines and lines at the root of nose; (3) naso-labial and vertical lines on neck; (4) radial lines about eyes, mouth, deep across back of neck; (5) fine meshes all over face. In 44% of the lines were equal in all parts of face, in the remainder 16.4% were frontal, 8.2% mandibular, 4.6% nasal. The cachectic type is more frequent in the old than gross or plump, and lines differ. The cachectic type looks older because lines are more numerous with pigmented plaques on face and hands. In the plump or gross type lines are deeper but less numerous, with few pigmented plaques. Menstruation disappears in 14.2% before the age of 40, 55.3% survive 41-50, 26.3% survive 51-60, 4.2% later. The duration of the period which separates nubility from the climacterium is 21-40 yrs., in 11.4% it goes beyond 40. There was a feeble correlation between beginning and end of menstruation. Stature decreases in 2.1% between the ages of 56-65, in 3% from 66-75, in 3.4% after 75. The index of spinal curvature was 93.5 at 56-65 yrs., 92.1 at 66-75; and 89.6 after 75. The curve has less value in the cachectic type than in the plump. Antero-posterior diameter of thorax increases 23 mm. between 56-65, 36 mm. from 66-75; transverse diameter decreases; thoracic index in the young is 135.7 at 56-65 yrs. it is 117.7, at 66-75 yrs. 109.2, and at 76 is 106.2. The curve of spinal column and thoracic index are closely correlated. The perimeter of thorax decreases 21 mm. from 60-75 yrs. There is a decrease in size of shoulders, arms, legs, and weight. Curves of deviation are greater for other characters than for perimeters. Size decreases more in the cachectic than in the plump or gross type in relation to stature. These facts are only approximate and errors are possible.—*R. B. Bean.*

11372. **[NEDRIGAÎLOVA, O. V.]** НЕДРИГАЙЛОВА, О. В. Национальные и социальные различия в мышечной силе и в процентных отношениях право- лево- и обоеруких. **[National and social differences in muscular strength and in division into right-handed, left-handed and ambidextrous.]** [French résumé.] Материалы по Антропологии Украины (*Anthrop. Ukraine*) 2: 66-76. 1926.—Measurement was made by means of dynamometer of Collin of muscular strength of pressure of right and left arms of 5740 recruits (3652 Ukrainian, 1380 Great Russian and 708 Jewish) classed according to social status and profession into 5 groups; peasants, day laborers, specialized laborers, technical workers, and intellectuals. The Jews have been divided into 3 groups only: laborers, technical workers, intellectuals. Very clear national differences are noticeable between mean values of muscular strength of Ukrainians and Great Russians and that of Jews. Jews possess in all social groups a mean strength less than that of the two other nationalities. Considerable differences exist in muscular strength of representatives of diverse social groups. Mean muscular strength of the 2 arms increases with rise in social status. Faculty of coordination of muscular contractions and capacity for realizing greater psychometric impulse are relatively greater with intellectuals. From this can be explained, in the opinion of the author, social differences in muscular strength. Difference between mean values of muscular strength of right arm and of left arm increases as social status rises.

Very clear national differences are noticeable with regard to right and left-handedness, the percentage of left-handed persons being more than twice as large with Jews than with Ukrainians and Great Russians. Number of left-handed persons decreases as social status rises. —*H. M. Allyn.*

11373. [NEDRIGAILOVA, O. V.] НЕДРИГАЙЛОВА, О. В. Социальные различия в росте, весе и некоторых размерах таза у женщин в связи с вопросом о корреляции между размерами матери и новорожденного. [Social differences in growth, weight and measurements of the pelvis in women in relation to the dimensions of the mother and new-born.] [French résumé.] Материалы по Антропологии Украины (*Anthrop. Ukraine*) 3: 198-210. 1927.—Differences are found for the following classes of Ukrainian and Russian women: peasants, houseworkers, skilled workers, technical workers, and intellectual women. The stature increases from the first to the last group: 152.9, 154.6, 155.2, and 157.0 cm., omitting intellectual women. The weight likewise increases. The pelvic dimensions change from 19.6 to 19.3 cm. for the conjugata externa from the peasant to the intellectual woman. The relation of the conjugata vera to the pelvic width at the iliac crests changes from 72.3 in the peasants to 71.7 in the intellectual women. The breadth of the iliac crests increases as the social status rises. Adipose tissue increases around the pelvis with age. The coefficient of correlation between mother and newborn is greater in stature between the mothers and sons, and in weight between the mothers and daughters. The correlation is greater in weight than in stature. The coefficient of correlation between height of mother and that of child is $+0.159 \pm 0.031$ for sons and $+0.096 \pm 0.032$ for daughters; for body length of mother and weight of child $+0.156 \pm 0.029$ for boys and $+0.139 \pm 0.029$ for girls; for body weight of mother and child the correlation is $+0.333 \pm 0.028$ for boys and $+0.345 \pm 0.028$ for girls.—*R. B. Bean.*

11374. **NOBACK, CHARLES V. Growth of infant male gorilla.** *Amer. Jour. Phys. Anthrop.* 14(2): 165-176. 7 fig. 1930.—An infant ♂ gorilla, estimated to be 20 mos. old, was received by the New York Zoological Society on October 31, 1928. Its weight was recorded at intervals of from 2 weeks to 1 mo. October 31, 1928, 7.84 kg.; April 15, 1930, 20.45 kg. At approximately 24 mos. of age, a full set of milk teeth was found. First permanent molars appeared at approximately 3 yrs. of age. 5 carpal bones present on radiographic examination at the time of arrival—multangular minor (trapezoid), capitatum (magnum), hamatum (unciform), triquetrum (cuneiform) and naviculare (scaphoid). The capitatum and hamatum were very definite, the naviculare very faint. On March 10, 1929, at 24 mos., the same bones were present, but all were much more definite, especially the naviculare. One year later, the multangular major (trapezium), pisiforme, and lunatum (lunar) were present in addition to the above. Centrale was present distal to the naviculare, in process of fusion with it. From observations on dentition and appearance of carpal bones, the rate of growth and development of the dental and osseous systems during the first 2½-3 yrs. of a ♂ gorilla's life seems to be 2-3 times as rapid as that of a ♂ human infant.—*Author (courtesy Wistar Bibl. Serv.).*

11375. **NOBACK, CHARLES V. Digital epiphyses and carpal bones in the growing infant female gorilla with sitting height, weight and estimated age.** *Zoologica [New York]* 11(5): 117-151. 16 pl. 1930.—9 carpal bones in each wrist of "Janet Penserosa," a living ♀ gorilla at the New York Zoological Park, were present before the 4th yr. One other ♀ gorilla, about 5 yrs. old, has been radiographed and all of its 8 carpal bones were present. The appearance and development of the carpals in the gorilla is very rapid in comparison with the human hand where the carpal bones are not normally present until about the 10th-12th yr. The epiphyses of the bones of the hand appeared very early. Fusion had apparently begun to take place between the metacarpal bones and their distal epiphyses at about the 3rd yr., the same time that the 1st permanent molars appeared. The order of appearance of the epiphyses, etc. appears to be the same as in the human subject, but the development is much more rapid. The 1st permanent molar teeth (6-yr. molars of man) appeared at about the 3rd yr. The total body weight of the living infant ♀ gorilla increased steadily from 7.84 kg. on October 31, 1928, to 24.09 kg. on October 20, 1930. Its weight on arrival was less than the average weight of a 1-yr. old human ♀ but after 2 yrs., the weight was greater than the average weight of an 8-yr. old child.—*C. V. Noback.*

11376. **NYESSEN, D. J. H. The races of Java. A few remarks towards the acquisition of some preliminary knowledge concerning the influence of geographic environment on the physical structure of the Javanese. (Indisch Comité voor Wetenschlappelijke Onderzoekingen IV.)** 122p. 28 fig. 1929.

11377. **OETTEKING, BRUNO. Primitive traits in the American aboriginal population.** *Inst. Internat. Anthrop. Ses. Amsterdam* 1928: (1-4): 1928.—A small selection of primitive traits serves to illustrate and justify a much more extended future investigation of the entire skeleton. Certain primitive features can be listed as follows: Exceptionally low cranial capacity is found not rarely, particularly in ♀♀; with this goes smallness of absolute dimensions. Low forehead occurs occasionally. Postorbital constriction is sometimes found, but usually not combined with strong supraorbital development except in Fuegians. Prognathism, especially of the alveolar region, and frequent occurrence of the torus occipitalis are noteworthy. The most primitive racial residua have been recovered in South America, as represented by the Lagoa Santa and Botocudo varieties, to which the Fuegians seem to be related. Excepting the archaic forms of South America it may be stated tentatively that in spite of the primitive characters the American Indian represents a more refined variety of the recent species of man, not only in the general sense but also within the Mongolid family.—*H. M. Allyn.*

11378. **OETTEKING, BRUNO. Some points in the morphologic evaluation of the American Indian.** *Proc. 23rd Internat. Congress Americanists (New York)* 1928: 853-855. 1930.—Morphological evaluation of human anatomical traits carried on from comparative angles must refer either to ancestral forms, or to variations of the same race, or to other races altogether, i.e., must deal either with the vertical or horizontal aspects of physical research, or both. As regards the American Indian, there are in his anatomy a number of morphologically and somatologically primitive features in spite of which he represents on the whole a more refined variety of the recent species of man, not only in a general sense but also in his racial domain, the mongoloid group of mankind.—*B. Oetteking.*

11379. **PARIN, B. W. Die Blutgruppen bei den Ostfinnen.** *Zeitschr. Rassenphysiol.* 2(4): 179-183. 1930.—In general the people of East Finland are characterized by a high incidence of group B, varying in different localities from 24.0 to 35.7. Groups O and A varied from 32.6 to 44.4 and 25.3 to 32, respectively. In contrast to these results the inhabitants of other parts of Finland have a lower incidence of B, about 17%.—*B. Levine.*

11380. **PICKERING, S. PRYOR. Correlation of brain and head measurements, and relation of brain shape and size to shape and size of the head.** *Amer. Jour. Physical Anthrop.* 15(1): 1-52. 2 fig. 1930.—29 crania of dissecting-room cadavers were measured, and corresponding measurements were taken on the brain of each specimen. Arc measurements were used on the brains between points which separate lobes that are functionally different. Points were chosen on the external vault which are known to lie closely superficial to the brain points, and like measurements recorded from the crania as from the brains. Volumes were taken and calculated. The cranial fossae were measured. The cranial measurements were then correlated with the brain mea-

surements and showed a positive relation between brain and cranial form. The correlation between the horizontal lengths of the lobes of the brain and the lengths of the cranial fossae gave an average figure of +.56. The correlation of cranial and brain volumes indicated that the brain was the major factor in influencing head size. Correlation of simple measurements showed that the brain exercised a controlling influence of 28 ± 10% on head form, the remaining percentage being controlled by other factors, such as size of face, muscular development, air sinuses, and ossification of the cranial base. Cranial capacity was greatest in brachycephalic heads. Dolichocephalic heads have longer but narrower brain lobes. A table is included from which the size of the brain parts can be calculated from head size.—*Author (courtesy Wistar Bibl. Serv.).*

11382. PRIESEL, RICHARD, und RICHARD WAGNER. Gesetzmässigkeiten im Auftreten der extragenitalen secundären Geschlechtsmerkmale bei Mädchen. *Zeitschr. Ges. Anat. Abt. II, Zeitschr. Konstitutionsl.* 15(3): 333-352. 32 fig. 1930.—Studies of 113 girls for a period of yrs. showed that the extragenital sexual characteristics appear in the following overlapping order: rounding of the hips, development of breasts, pubic hair, axillary hair. The variant was the precipitate appearance of the last. Apparently the succession is related to the varying response of the recipient organ to the sexual hormone, whether one or several. The menarche is not the end of pubertal development but, under physiological conditions, it is never an early sign.

11383. RISAK, ERWIN. Über die verschiedenen Arten der männlichen Genitalbehaarung. *Zeitschr. Ges. Anat. Abt. 2, Zeitschr. Konstitutionsl.* 15(2): 164-176. 4 fig. 1929.

11384. RITT, ESTELLE FINE, and RUTH OTIS SAWTELL. Growth studies by Roentgen ray. *Amer. Jour. Phys. Anthrop.* 14(1): 1-8. 1 fig. 1930.—The amount of distortion constant in every film of a given part of the body made at a standard distance from the tube was calculated, and comparison was made between the measurement on the film minus this error and the measurement on the child. 700 records of the forearm of young children measured at the same time on individuals and on their roentgenograms showed that although theoretically the small constant elongation on the film represented the difference by which it exceeded the diameter on the living, actually measurements on the living were slightly greater, due to the thickness of the skin. In practice, then, measurements of long bones from roentgenograms can be substituted for analogous measurements on the living, and, because of greater accuracy, should be preferred.—*Author (courtesy Wistar Bibl. Serv.).*

11385. ROSENSTERN, J. Über die körperliche Entwicklung in der Pubertät (auf Grund von Individualuntersuchungen). *Zeitschr. Kinderheilk.* 50(1): 1-25. 11 fig. 1930.—Examinations were made on about 250 children, aged 9-15 yrs., 34 boys and 32 girls under observation for more than 1 yr. Measurements of height; wt.; circumference of neck and chest; width of shoulder and hips; sitting height; conjugata externa; length of arms, legs, and hands; and fatty deposits on cheek, abdomen, hips, and thigh were determined. Distribution of hair, size of thyroid, mammary glands, respiratory type, pulse, and blood pressure were noted. Martin's technic was used. This 1st report deals with the lengthening and coarsening of the face during puberty, attributable to the hypophysis.

11386. [RUBASHKIN, V. IA., and L. I. LEIZERMAN.] РУБАШКИН, В. Я., і Л. Э. ЛЕЙЗЕРМАН. Изогемоагглютинаційні групи и показники конституцийй у червоно армійців родом з Украіни. [Isohemoagglutination groups and constitution indexes in Ukrainian Red Army Soldiers.] [German translation.] *Ukrainisches Zentralbl. Blutgruppenforsch.* 4(3): 144-155. 17 pl. 1930.—Investigation embraced 2438, of whom 2075 were aborigines of Ukrainia. Aim was to determine distribution of blood groups among the Ukrainian population, and the possible correlation between blood group and constitutional type. Blood groups were distributed as follows: O—31%; A—39.4%; B—22%; AB—7.6%. The following correlations were observed: Group O: predominantly persons of "strong" constitution, normal chested and narrow chested, well nourished, brachycephalic, broadshouldered, "weak" and "wide chested"—in smaller numbers, likewise mesocephalics. Group A: strong, broad chested, with normal shoulder measurement; also, dolicho- and mesocephals in a somewhat larger percentage than on the average. Group B: "Strong" constitutions are met here in smaller number than on the average; "weak," in larger number. Somewhat more frequent are persons less well nourished, predominantly hyperbrachycephals. Narrow shouldered are twice as rare as on the average. Group AB: the constitutional types are considerably less "strong," "weak" types predominate. Here are more meso- and brachycephals, fewer hyperbrachycephals; broadshouldered types are twice as rare as on the average.

11387. SALLER, K. Die Grundlagen und die Ordnung der menschlichen Konstitutionen. *Endokrinologie* 6(4): 241-248. 1930.—The author concludes that a constitution type as related to species, race, family, sex or age, is based upon a natural scientific foundation, but that the idea of a "constitution type" as related to the norm is unscientific and based only on conventional agreement. Incidentally, he believes that hormones may effect the individual but not the species.—*B. Cunningham.*

11390. SANKAS, S. H. Relation of cranial module to capacity. *Amer. Jour. Phys. Anthrop.* 14(2): 305-315. 1930.—The object of the research was to test further the difference in the module-capacity relation in the 2 sexes which Hrdlička reported in Science of February 4, 1927. The work was carried on on 400 undeformed adult Peruvian skulls, ♂ and ♀, in the U. S. National Museum. These skulls are from Pachacamac, Chicama, and Chilca. The utmost effort was made to assure the proper sexing of the specimens. The measurements made were: the standard length, breadth, and basiobregmatic height, the mean of which gives the cranial module, and the capacity (Hrdlička's method). The capacity was taken twice on each skull, the mean being recorded. The percental relation of the module to capacity was then ascertained. The results, while showing some group peculiarities, corroborate Hrdlička's findings; besides which there are interesting individual conditions.—*Author (courtesy Wistar Bibl. Serv.).*

11391. SCAMMON, RICHARD E. The ponderal growth of the extremities of the human fetus. *Amer. Jour. Physical Anthrop.* 15(1): 111-121. 1930.—An analytic study of the ponderal growth of the extremities of the human fetus based on a series of determinations made by Corrado some 30 yrs. ago. The study shows that the growth of each of the extremities and each segment thereof may be approximated by an expression representing a coefficient of the total or crown-heel length of the body raised to a power ranging, in the series, from about 3.6 to 3.8. The absolute velocities of growth of these parts of the body increase in the order of 100-fold during the fetal period. The relative velocities of growth decline markedly during the same interval. The weight of the upper extremity increases with respect to that of the lower extremity, and the weight of the hand increases with respect to the weight of the entire upper extremity, in the fetal period. But the weight of the foot decreases both with respect to the weight of the entire lower ex-

tremity and with respect to the weight of the hand.—*Author (courtesy Wistar Bibl. Serv.).*

11392. SHAPIRO, H. L. Old New Yorkers. A series of crania from the Nagel Burying Ground, New York City. *Amer. Jour. Physical Anthrop.* 14(3): 379-404. 2 fig. 1930.—A small series of 15 ♂ crania from the Nagel Burial Ground in New York City and dating approximately from the 18th century were studied. A comparison of this group with various English and Scotch crania revealed the fact that this series of Old New Yorkers appears to be a sampling from a population typified by 3 17th-century London groups and one from the Lowlands of Scotland. The evidence, although insufficient for a final interpretation, warrants the tentative hypothesis that the generalized colonial type to be found in New York in the epoch just prior to the Revolution was essentially similar to the average Englishman of the period. Furthermore, in all probability, it may be assumed until more data are forthcoming that the English immigrants to this country were not a selected group. In addition, the stature of the Nagel series, reconstructed from measurements on the femur, furnishes subsidiary confirmation to the general belief that stature has been increasing in the Old American stock. Finally, by estimating cephalic means from the cranial averages of the Nagel series, a cursory comparison with living Old Americans was possible. Recognizing the error inherent in such a procedure, it is interesting to note that, even after a century, apparently the Old Americans have remained similar to their Colonial ancestors of New York.—*Author (courtesy Wistar Bibl. Serv.).*

11393. SIDHOM, GIRGIS, and D. E. DERRY. The dates of union of some epiphyses in Egyptians from x-ray photographs. *Jour. Anat.* 65(2): 196-211. 1 pl., 2 fig. 1931.—Examination of over 400 Egyptians aged 14-22 yrs. was undertaken to learn whether the alleged earlier maturity of Egyptians as compared with Europeans is corroborated by earlier union of the epiphyses. The results appear to show that Egyptian ♂♂ are definitely earlier than English in the union of at least some of the epiphyses of the upper limb. At the same time the wide divergence in results as between the authors and the observers they have quoted, as well as between those observers themselves, seems to illustrate the unreliability of results obtained even from x-ray photographs.

11394. SILVA CORREIA, ALBERTO GERMANO. Les Lusos—Descendants de l'Inde Portugaise. (Étude anthropologique.) *Arquiv. Escola Méd.-Cirurg. Nova Gôa. Sér. A, Fasc.* 2: 87-216. 1928.

11395. SITSEN, A. E. The scapula of the Malay. *Mededeel. Dienst Volksgezondheid Nederlandsch-Indie* 19(1): 1-22. 1930.—The ♂ scapula is smaller in Malay than in European. The difference in length amounts to 7% and is principally, perhaps entirely, explained by the shorter build of the Malay, as is true also for width. The difference in width is 14%. The scapular index (Martin) is larger in Malay than in European; the scapula therefore is relatively wider in Europeans. When reducing the width of the scapula to its 2 components, a difference in the supraspinal groove seems doubtful. The supraspinal index (Frey) is 40.2 in European, 41 in Malay. Infraspinal index (Frey) shows a distinct difference, amounting to 117 in European and 109 in Malay. The upper groove is therefore the same in both, whereas the lower groove is relatively narrower in Malay. This is clearly apparent in the spinal groove index (Frey), which is 34 for European, 38 for Malay. In comparing the variation-range of the infraspinal index of European and Malay, there seems to be little difference (99-136 in European, 93-139 in Malay). This shows that there is not an innate difference, but that it is due to some external influence. The higher indices so often occurring in Europeans are rare in the Malay. If the higher values are considered as due to heavy labor, it is reasonable to attribute the narrower scapula of the Malay to less muscular labor. The number of straight and scaphoid scapulae is small in the Malay; this also may be due to less heavy labor. The scapula of the ♀ Malay is smaller than that of the ♂ in all directions. The difference in width is 12%. Since the Malay ♀ is 6% shorter than the Malay ♂, the ♀ bone is 4% shorter and 6% narrower than the ♂. This difference is also seen in the supra- and infraspinal grooves, with sexual differences of 7% and 5%. The minima of the variation-range in both sexes are the same for both ♂ and ♀, although the maxima of the ♂ exceed those of the ♀. The infraspinal index in ♀♀ is 91-120, in ♂♂ 93-137. The supraspinal index is 32-45 in ♀♀, 31-52 in ♂♂. The same is found in a comparison between European and Malay. This phenomenon leads us to ascribe this difference to the lighter labor performed by woman. The scapular width-length angle (Martin) was 85° (75-95) in Malay ♂♂, 85° (73-93) in Malay ♀♀. For the Papuan, Van den Broek also obtains 85° (82-89). In the European the value is almost the same. The build of the bone is more sharply defined by the size of the supra- and infraspinal angles. These appeared to have about the same average for both sexes: the variation-range however shows that the wider spinal grooves also change the whole shape of the scapula.—*Author's summary.*

11396. ŠKERLJ, B. Beiträge zur Anthropologie der Slowenen. I. Farbenkomplexionen an 416 Schulkindern der achtklassigen Volksschule in Ljubljana-Moste. *Zeitschr. Morph. u. Anthrop.* 28(3): 213-237. 1930.—In this investigation it was found that the correlation between eye- and hair-color is not high (about ½). The Slavonians belong to the light-colored peoples of Europe and are clearly distinguished in this regard from Croatians and Serbians, while they approximate more closely the Northern Slavs (especially Czechs, cf. Škerlj, '27 and '28). The author has established the fact that the hair darkens but little, the eyes not at all, but rather become somewhat lighter. Red hair is regarded as anomalous. It is apt to appear in combination with freckles. The author can not at present express exactly by an index a correlation between erythrism and ephelides although it is more than probable, in fact almost certain, that such exists. Most clearly are revealed sex differences in complexion which appear in relatively small children. In this respect the differences in the correlation indices are especially noteworthy and, to the knowledge of the author, have not hitherto been established.—*B. Škerlj. (transl. by C. J. Connolly).*

11397. SLOBOSIANO, HORIA, et P. HERSCOVICI. Étude sur le poids, la taille et le buste des foetus et des nouveau-nés à terme. *Nourrisson* 17(3): 133-144. 7 fig. 1929.—The author studied 125 newborn children (78 of premature birth), and a number of fetuses of 6-9 mos. The latter had to be calculated by their lengths as the most reliable factor to which different weights corresponded, giving rise to hypo- and hypertrophical fetal weight conditions. Further investigations were carried on according to Quetelet's, Manouvrier's and Pirquet's proportional calculations of weight, trunk length and length of the lower extremity in their various combinations.—*B. Oetteking.*

11398. SMITH, G. ELLIOT. The significance of Peking man. *Nature [London]* 127(3197): 202-204. 2 fig. 1931.—A discussion of *Sinanthropus** and its relationships to *Eoanthropus* and *Pithecanthropus*. The bones of the skull are exceptionally thick as in the Piltdown skull, and both belong to the Lower Pleistocene; but the skull has great projecting eyebrow ridges as in *Pithecanthropus*, which it resembles in other ways. *Sinanthropus* occupies a position between the other 2 genera.

11399. SNYDER, LAURENCE H. The "Laws" of serologic race-classification. Studies in human inheritance IV. *Human Biol.* 2(1): 128-133. 1930.—In order to bring the anthropologic applications of the blood groups to a definite status, the following laws of serologic race classification are offered, with evidence for each: (1) Any people whose blood group distribution is being studied may be expected to show blood group frequencies similar to those of other peoples known to be related to it. (2) If any people shows blood group frequencies different from those to be expected based on the frequencies

of other peoples known to be related to it, the conclusion may be drawn that the former has undergone racial crossing of some sort which the latter have not undergone, or vice versa. (3) If any people shows blood group frequencies similar to a group of peoples not known to be related to it, the conclusion may be drawn that the former traces back to the latter somewhere in its ancestry, or else that the former has undergone crossing with the latter group or some similar people. (4) If any people lacks one or both of the blood group mutations, as evidenced by an extremely low value of p or q, it may be assumed that this people became isolated from the rest of mankind before the respective mutations took place, or before they spread very far.—*L. H. Snyder.*

11400. STEVENSON, PAUL H. Anthropometry in China: an extended outline of research. *China Med. Jour.* 40(2): (1-33). 11 fig. 1926.—Emphasizes necessity of equipment, program of investigation and cooperation for racial anthropometric study. Anthropometric plane, spreading caliper, sliding compass, tape, and weighing scale are described. 15 measurements constitute a minimum requirement: Stature, sitting height, span, chest girth, weight, maximum head length and breadth, head height, face length (from gnathion below to nasion above), full face length (including forehead), minimum frontal breadth, maximum bizygomatic breadth, bigonial breadth, nose length and breadth. 10 optional measurements: Hand length and breadth, foot length and breadth, girth biceps, maximum and minimum girth forearm, girth thigh, maximum and minimum girth leg. Visual observations: Skin color, hair, form, color and distribution, eye color, form and direction palpebral fissure, direction eye slit, epicanthic fold, teeth. Team work and special prepared record blanks necessary.—*S. A. Weisman.*

11401. STEVENSON, PAUL HUSTON. Adaptation of Hrdlička's compass for direct head-height measurements. *Amer. Jour. Phys. Anthrop.* 13(3): 469-475. 2 fig. 1930.—This describes a simple attachment to the Hrdlička compass, which eliminates intermediate steps in taking the head-height measurement. The device consists of a vertical graduated rod; it is attached to the scale bar of the Hrdlička compass and reaches from the scale bar to the compass tips; it can move horizontally and up and down on the scale bar. The head-height measurement is read on this graduated vertical rod.—*Author (courtesy Wistar Bibl. Serv.).*

11402. SULLIVAN, LOUIS R. (prepared for publication by CLARK WISSLER). Observations on Hawaiian somatology. *Bayard Dominick Expedition Publ.* 13. 76p. 5 pl. 1927. Pr. $2.—Anthropometric measurements and quantitative somatic observations were made upon adults of Hawaiian descent, living in Hawaii; approximately 200 ♂♂ and 175 ♀♀ regarded as pure Hawaiian, and varying numbers of Hawaiian-White and Hawaiian-Chinese mixtures. Almost the entire paper is taken up with the data, given by individuals in full. The averages and deviations for each measurement have been calculated first in 5-yr. age-groups, revealing progressive age changes in the proportions of the head and face, as: the width of nose increases to the age of 60, the minimum frontal diam. of the head decreases between 30 and 60. The gross tabulations for the Hawaiian adults are under 2 age-groups, 20-59 and 60 plus. The other groupings are Hawaiian-Chinese, Hawaiian-S. European and Hawaiian-N. European. Comparisons between mixed and pure Hawaiians place the former in an intermediate position to the respective parent stocks. Comparisons are made with other Polynesian peoples, suggesting that the Hawaiians are nearer to the Tongans and Marquesans than to the Samoans and other Polynesians.—*L. R. Sullivan.*

11403. TODD, T. WINGATE. Age changes in the pubic bone. VIII. Roentgenographic differentiation. *Amer. Jour. Phys. Anthrop.* 14(2): 255-271. 3 pl. 1930.—Roentgenographic examination can give general information regarding the stage of differentiation of the symphysial face, but the method of observation precludes exactitude in diagnosis sufficient to identify age with that precision attainable on examination of the bone itself. No sex- or stock-linked features are discernible in the differentiation by roentgenographic methods. Distinctions in differentiation ascertainable from the bones themselves are slight and, it may be, equivocal. Gross estimation of age as a check upon evidence from other skeletal observations may be extremely helpful, and specific data are given in the text.—*Author (courtesy Wistar Bibl. Serv.).*

11404. TODD, T. WINGATE, and BARBARA TRACY. Racial features in the American negro cranium. *Amer. Jour. Physical Anthrop.* 15(1): 53-110. 22 fig. 1930.—A detailed study of the American negro ♂ skull and a comparison of it with both African and white series demonstrates but a single type of negro cranium of characteristic features, some of which are more readily modifiable than others by hybridization. There is nothing characteristic of stock in suture pattern, but the cranium, in its growth, passes through certain definite successive phases, and the interruption of growth at one or other of these stages gives the clue to a particular adult form.—*Authors (courtesy Wistar Bibl. Serv.).*

11405. TORII, RYŪZO. Fossil species of man and their culture. [In Japanese.] *Jour. Geogr. [Tokyo]* 42 (500): (592)-(598). 1930.

11406. TROTTER, MILDRED. The form, size, and color of head hair in American whites. *Amer. Jour. Physical Anthrop.* 4(3): 433-445. 1930.—Sex and age comparisons for hair-index measurements, cross-section area of the hair shaft, and color of hair samples were made in order to determine possible changes in the form, size, and color of the hair with increasing age. Measurements consisting of the greatest and the least diameters of the shaft at a given point were obtained on 10 hairs from each sample of 340 individuals. The color determinations were made with the "Haarfarbentafel nach Fischer-Saller." The difference in hair index between ♂ and ♀ groups as a whole was so slight that it is probably insignificant, although there was some variation between the subdivisions—the most conspicuous of these existing between the youngest groups. In the ♀ group the youngest individuals presented the lowest index, while in the ♂ group the youngest individuals presented the highest index. No difference was found between adult ♂ and ♀ groups in the areas of cross-sections of the hair shaft (obtained by the following formula: greatest diameter/2 $\times$ least diameter/2 $\times \pi$). However, young ♂♂ present areas equal to those of the adult at a slightly earlier age than do ♀♀. The incidence of the darker tones increased with the increasing age periods. Gray hairs exceeded in area their largest pigmented neighbors in about ¼ of the cases.—*Author (courtesy Wistar Bibl. Serv.).*

11407. TROTTER, WILFRED. The functions of the human skull. *Nature [London]* 123(3101): 533-537. 1929.—Report of a lecture giving anthropological and general evolutionary conclusions based on the study of the physiology and pathology of the brain and skull. The brain is an encapsuled organ, its capsule being the skull. Organs may be classified in 3 groups according to the rigidity of their capsules; in (1) the capsule is freely extensible, in (2) the capsule is only slightly extensible, in (3) (including only the brain) the capsule is inextensible to all physiological forces. These conditions have important effects on the mechanics of the circulation. In any tissue the flow of blood must be continuous; in organs of the first 2 groups this is made possible by the extensibility and elastic recoil of the capsule. In the case of the brain the mechanism is different; it expands with each pulse, but as the skull is unyielding, room must be made at each pulsation by the expulsion of a corresponding volume of the low pressure intra-cranial fluids. The low pressure outflow that must accompany each arterial pulsation is chiefly in the form of venous blood. Therefore flow of blood in the veins must be quite free. But the venous pressure is low so that any abnormal swelling of the brain causes collapse and obstruction of a greater or less venous territory. The

rigidity of the skull is therefore the reason why, apart from purely destructive processes, all cerebral symptoms are of circulatory origin. The brain, when bruised, must return to its normal size or its circulation will be permanently disturbed. This it does very slowly, one of the most important functional effects of its rigid encapsulation. The protective function of the modern European skull is very imperfect. Under external violence it readily sustains disortion which frequently leads to bruising of the brain. The liability of the skull to distortion under violence is greatest in the modern European. In other races, e.g., the negro, external violence less easily produces contusion of the brain. The European therefore has lost some of the protective strength of skull that other races possess. However much more of its protective massiveness it may lose, the skull must always maintain enough rigidity to preserve its form, since one of its most important functions is to support the brain. If the low strength of the European skull produces a high susceptibility to disabling minor injuries it may be expected to have some corresponding advantage. This probably lies in freeing the cranium as far as possible from any functions but those of skeleton and capsule of the brain. If the cranium has other functions than these to fulfil, its freedom to vary exactly with the brain must be, in however slight degree, limited. Since free variability of the brain through a small range is probably of value in fitting man for civilization it is possible that the freeing of the cranium from accessory functions has been a factor in human evolution. The anterior end of the segmental animal was the natural site for the chief nucleus of a centralized nervous system. The same region was inevitably annexed for the entry to the respiratory and digestive tracts. The consequent crowding of function into 1 extremity reveals 2 tendencies in conflict—the tendency on the one hand for the brain skeleton to be made use of for functions connected with other systems, and the tendency of the brain to struggle for freedom from such burdens. When for example the cranium has been involved in the apparatus of defence and attack such as horns, antlers, fangs and tusks, the progress of the brain has been checked. The ancestors of man with the steady avoidance of specialization to which he so largely owes his zoological position, kept their crania free from such encumbrances and made possible the progressive evolution of the brain. The apparent tendency now visible towards a continued reduction of the strength of the skull seems to be a manifestation of the same process.—*W. Trotter.*

11408. TSUKAHARA, Y. Schädelmessungen am Lebenden, mit besonderer Berücksichtigung der Augengegend, angestellt an Formosa-Chinesen und Japanern in Formosa. *Taiwan Igakki Zasshi* [*Jour. Med. Assoc. Formosa*] 309. 83-84. 1930.—About 30,000 persons were studied craniologically. At birth all of the measurements were greater in the Chinese. Around the 10-15-yr. period the Japanese index surpasses that of the Chinese. In both races the figures for the ♂ generally exceed those for the ♀, but at adolescence the ♀ index equals or even exceeds that of the ♂. These values parallel weight and body size.—*E. C. Faust.*

11411. BRICE, ARTHUR T., Jr. Notes on a combined peroxidase Wright's stain for blood films. *Stain Tech.* 5 (3) : 101-102. 1930.—Oxydase reagent. Dissolve 0.3 gram of benzedine base in 100 cc. ethyl alcohol. Add 1 cc. of a saturated aqueous solution of Na nitroprusside. This reagent should keep from 8 mos. to a year. Thin films should be made and dried in air. The slide or cover-slip is first flooded with the oxydase reagent, which is allowed to act for 1-1½ min. An approximately equal portion of a freshly made 1/1200 hydrogen-peroxide solution is then poured on the slide and allowed to act for 3 min. The slide is then washed thoroughly under the tap and dried. The film is then stained by Wright's method according to the usual technic.—*Author* (*courtesy Wistar Bibl. Serv.*).

11412. CALHOUN, M. LOIS. Technic for the isolation of epithelium. *Stain Technol.* 6 (2) : 65. 1931.—The tissue is washed in saline and then in 1.5% aqueous Na bicarbonate. It is then put in Muller's fluid dissociator for 36 hrs. When the tissue is removed from the fluid, lightly brush the surface of the epithelium with a small brush. Transfer the cells to a microscopic slide and dry slightly. Fix in methyl alcohol, rinse in distilled water, and stain with Harris's hematoxylin and eosin. Mount in balsam.—*Author* (*courtesy Wistar Bibl. Serv.*).

11413. CLARK, E. R., H. T. KIRBY-SMITH, R. O. REX, and R. G. WILLIAMS. Recent modifications in the method of studying living cells and tissues in transparent chambers inserted in the rabbit's ear. *Anat. Rec.* 47 (2) : 187-211. 8 fig. 1930.—The method of introducing transparent chambers into the rabbit's ear has reached a stage in which approximately standardized types of chambers are available for most investigations in which the use of the method is desirable. Four types of chambers are described in this article and directions given for making them and inserting them in the ear. The "bay type" chamber is suitable for long-continued observations of newly growing capillaries and of blood cells which are free from the motion attendant on variations in the tissue tension. It may be adapted for studies concerning the effect of chemical solutions, gases, etc., on living tissues. The round-table chamber is used for general studies of newly formed blood vessels and lymphatic vessels and for detailed cytological studies. This type may be adapted for transplanting tissues and foreign substances into the vascularized area. The "preformed-tissue" chamber enables one to study the vessels already present in the ear and is suitable for physiological and pharmacological studies on such vessels. By making slight changes in this last type, the so-called combination chamber is formed which enables the investigator to study the original ear vessels and new-growing vessels in the same specimen. A brief résumé is given of the types of problems being investigated in this laboratory by this means.—*Authors* (*courtesy Wistar Bibl. Serv.*).

11414. CONN, H. J. The history of staining. The staining of blood and parasitic protozoa. *Stain Tech.* 5 (4) : 127-134. 1930.—This paper, the 7th of the series on the history of staining, takes up the stains used primarily for blood and blood parasites. Chief attention is given to compound stains of the Romanovsky type; but other kinds of blood stains, especially the vital stains for blood, are also discussed.—*Author* (*courtesy Wistar Bibl. Serv.*).

11415. DAVENPORT, H. A. Block staining of nervous tissue with silver. Studies of fixatives, lipid solvents, and reducing solutions. *Stain Tech.* 5 (4) : 139-147. 1930.—Silver stains of the Cajal type, made on spinal cord of cats, were studied to determine the limits of favorable ammonia concentration in alcohol as a fixative and the comparison of ammoniated alcohol with alcohol-chloroform and alcohol-pyridine mixtures. Such material subsequently extracted with various lipid solvents showed staining of a generally similar character. More intense staining was seen after the alkaline fixatives, and best penetration of stain into the blocks after the most thorough extraction of lipids. Experiments with reducing solutions which contained various proportions of pyrogallic acid and formalin indicated that pyrogallic acid is the essential ingredient. Postmortem autolysis up

to 5 hrs. caused no change in fiber staining.—*Author (courtesy Wistar Bibl. Serv.)*.

11416. DAVENPORT, H. A. Block staining of nervous tissue with silver. II. Trichloracetic acid, sulfosalicylic acid, Hofker's and Carnoy's fluids as fixatives. *Stain Technol.* 6(2): 37-40. 1931.—Alcoholic solutions of sulphosalicylic acid, trichloracetic acid, and Hofker's solution fixed mammalian spinal cord with less shrinkage than ammoniated alcohol, but during the necessary alkalinization, washing, and silvering, the acid-fixed specimens shrunk more than those fixed in the alkaline alcohol. Specimens fixed in Carnoy's fluid shrunk most. Successful silver stains were obtained after all these fixatives.—*Author (courtesy Wistar Bibl. Serv.)*.

[A method for decoloration of preparations impregnated with Cajal's photographic method.] *Boll. Soc. Ital. Biol. Sperim.* 5(5): 780-781. 1930.—The decoloration of preparations impregnated with Ag proceeds quickly and completely by means of Lugol's solution.—*M. Comel.*

11420. GESCHICKTER, CHARLES F. Fresh tissue diagnosis in the operating room. *Stain Tech.* 5(3): 81-86. 1930.—A polychromatic stain giving color reactions closely simulating hematoxylin and eosin, without overstaining and obscuring the finer detail of the cell, is as follows: To 4 parts of 1% aqueous azure A (azure I) which has been filtered, add very rapidly 1 part of filtered 0.5% aqueous Erie garnet B. The mixture is immediately filtered to prevent precipitation. Occasional refiltering may be necessary if the mixture has been standing a month or more. Float tissue slices from a freezing microtome directly into distilled water; pick them up with a glass rod and immerse into the stain in a small section dish. Staining time varies with different tissues, but 10-15 seconds usually gives the most satisfactory results. Lift sections from the stain, still on the glass rod, float through 2 changes of distilled water, and transfer to a clean glass slide. Place a large drop of 40% glucose on a clean cover-slip and immediately invert over the section. Allow ½-1 min. for it to clear. It is best to employ an intense artificial light for illumination (an ordinary 40- or 60-watt bulb is sufficient).—*Author (courtesy Wistar Bibl. Serv.)*.

11421. GOUGH, J. Acetaldehyde as a fixative for neuroglia. *Jour. Path. and Bact.* 34(4): 419-421. 1931.—A 20% aqueous solution of acetaldehyde used as a fixative for nervous tissue, is a selective agent for the demonstration of fibrous astrocytes in animal and human material. After 6-24 hrs. fixation, frozen sections are cut and stained by means of ammoniacal silver carbonate or Cajal's gold-sublimate solution. The method has the advantage of requiring only a short period of fixation.—*J. Gough.*

11423. HEARD, OSBORNE O. A photographic method of orienting serial sections for reconstruction. *Anat. Rec.* 49(1): 59-70. 5 fig. 1931.—The orientation of paraffin serial sections is obtained by the use of photography during the process of cutting. A special camera carrying standard moving-picture films is mounted over the microtome and vertical illumination is provided. Each undisturbed potential section is photographed in relation to the camera aperture before the knife cuts it from the block. The finished orientation film is projected into a fixed master frame coinciding with the enlargement of the reconstruction, to reestablish the original relationship of the specimen and camera aperture. Serial photomicrographic records made on bromide paper at the required magnification are superimposed on the projected film image, and right-angle orientation lines are transferred to the records.—*Author (courtesy Wistar Bibl. Serv.)*.

11424. LANDAU, E. Saulėžolin-nauji dažai histologijos technikoje. [Saulezolin, a new dye for histologic use.] [In Lithuanian, with German summary.] *Medicina [Kaunas, Lithuania]* 11(1): 30-31. 1930.—The black husks of sunflower seeds yielded on boiling a brownish violet dye similar in appearance to hematein and changed by mixture with alum or $Al_2(SO_4)_3$ to dark violet (while hematein is changed by alum to blue violet). Since "helianthin" has already been given to another dye, Landau calls this dye by the Lithuanian equivalent, "saulezolin."—*From author's summary.*

11425. LARSON, EDITH E. Further experimentation with a new differential staining method for connective tissue combined with the ordinary hematoxylin-eosin stain. *Stain Tech.* 5(2): 73-74. 1930.—Tissues fixed in any of the more common fixing fluids and embedded in either paraffin or celloidin may be used. Sections are stained in a solution made up like Delafield's hematoxylin except that hematein is used and ripening is omitted. After treating with tap-water the sections are stained with eosin B (0.5% in 25% alcohol) for 1 min. or longer; then run up to 95% alcohol and treated with orange G (0.5% in 95% alcohol) for 15 sec. or less; finally dehydrated with absolute alcohol, cleared, and mounted.—*Author (courtesy Wistar Bibl. Serv.)*.

11426. MAINLAND, DONALD. A study of the sizes of nuclei in ovarian stroma. *Anat. Rec.* 48(2): 323-340. 1931.—Measurements have been made of the longitudinal and transverse axes of 1000 nuclei in the projected, magnified image of the cortical stroma of a paraffin section from a formalin-fixed human ovary. At the magnification used (1824) the mean longitudinal axis is 14.028 mm.; standard deviation of series: ±5.42. The mean transverse axis is 4.812 mm.; standard deviation of series: ±2.45. Coefficient of correlation of these 2 axes: +0.27. An index, viz.: transverse axis/longitudinal axis, has been calculated for each nucleus. Regression equations and analysis of variance show that the mean index increases proportionately to the transverse axis as this axis increases from 0.1 to 6 mm.; but as the axis increases from 6.1 mm. to 16 mm., the mean index remains unchanged. These 2 classes correspond, respectively, to: (1) cylindrical or fusiform, "fibroblastic" nuclei and, (2) flat, pale, mottled "lamellar connective tissue" nuclei. The nuclei of over 6 mm. transverse axis occur irregularly in clumps at varying intervals.—*Author (courtesy Wistar Bibl. Serv.)*.

11427. MILLER, WILLIAM SNOW. The use of blotting-paper for reconstructions. *Anat. Rec.* 48(1): 191-196. 4 fig. 1931.—Some of the advantages and disadvantages of wax and blotting-paper for reconstruction purposes are considered and new mechanical aids for use with blotting-paper are described.—*Author (courtesy Wistar Bibl. Serv.)*.

11434. TURNBULL, H. M. A Jenner stain for sections. *Jour. Path. and Bact.* 34(2): 277-279. 1931.—Particulars are given for staining paraffin sections of tissue fixed in formaldehyde, preferably buffered isotonic formaldehyde, with a solution of Jenner's stain in methyl alcohol, differentiating with ethyl alcohol and mounting in Gurr's medium. The resulting colors are comparatively simple and clean. Increasing degrees of basophilia of cytoplasm are indicated by deepening shades of blue. Nucleoli are stained pink. Neutrophil granules are pink. Eosinophil granules are brick-red in leucocytes and ripe myelocytes, but have a more carmine tinge in pro-myelocytes. Basophil granules are blue-purple metachromatic to red in tissue mast cells, but a purple that is less blue in leucocytes and particularly myelocytes. Azurophil granules are not stained. As the cytoplasm becomes hemoglobinated in ripening erythroblasts it passes from blue through shades of purple to pink.—*H. M. Turnbull.*

11435. ZIFFERBLATT, ARNOLD H., and HENRY K. SEELAUS. Improved method of refrigeration of whole blood for centrifugation. *Anat. Rec.* 47(2): 229-238. 3 fig. 1930.—The improved method for refrigeration of whole blood during the process of centrifugation entails but a slight change in the standard centrifuge accessories. The unit method of refrigeration insures a degree of frigidity impossible of attainment with the system heretofore employed. When the individual unit is once assembled, it requires no further attention, except the replacement of paraffined centrifuge tubes and refilling of the trunnion cup with water. Under conditions necessitating the recentrifugation of a quantity of blood, a replacement unit is employed from which the brass tube used in its preparation is withdrawn, leaving a cylindrical channel in the ice jacket for the insertion of the centrifuge tube containing blood. The refrigeration obtained by use of the improved unit is lower and better conserved.—*Authors (courtesy Wistar Bibl. Serv.).*

11436. ZIFFERBLATT, ARNOLD H., and HENRY K. SEELAUS. Embryo-chick plasma. The introduction of a growth-activating medium for the cultivation of embryonic-chick tissue in vitro. *Anat. Rec.* 48(2): 367-377. 4 fig. 1931.—The observed rapidity of the embryonic development of the chick has led to the conclusion that the growth-stimulating substances contained in embryo blood must be present in far greater quantity than in the blood of the adult fowl, particularly in advanced age. Hence embryonic plasma, when employed for the cultivation of embryonic tissue in vitro, should furnish a medium both nutritive and isotonic to the explant. Embryo blood is collected from the extra-embryonic circulatory apparatus of the chick in the following manner: An egg of the proper incubated age (16 days) is opened and the vitelline vessels or sinus terminalis are located. A modified aneurysm needle is passed beneath the selected blood vessel to a point calculated to carry the vessel across the grooved director of the instrument. The blood flow is diverted from its customary channel by partially opening the vessel at a point coinciding with the center of the wide end of the V-shaped groove. Through this opening in the vessel wall the escaping blood flows down the groove in the director to the collecting vessel. Care of the embryonic blood to preclude premature coagulation is in all respects identical with that employed in the care of adult chicken blood. —*Authors (courtesy Wistar Bibl. Serv.).*

(See also in this issue Entries 9346, 9413, 9452, 9770, 9859, 10008, 10009; 10620, 11584)

11438. CRABB, EDWARD D. The origin of independent and of conjoined twins in fresh-water snails. *Zeitschr. Wiss. Biol. Abt. D, Roux' Arch. Entwicklungsmech. Organ.* 124(2): 332-356. 14 fig. 1931.—Polyvitelline eggs were found in *Viviparus malleatus, V. contectoides, Campeloma decisum, Lymnaea palustris, L. stagnalis appressa, Physa ancillaria, P. sayii, P. gyrina* and *Planorbis (Gyraulus) umbilicatellus.* The development of eggs having naturally fused or experimentally fused vitelli, and the vitelli fragmented, or otherwise injured by ultraviolet rays, centrifugal force or glass needles, was studied in *P. gyrina, P. ancillaria, L. s. appressa* and *L. palustris.* In one case 2 naturally fused *L. palustris* trochophores were cultured 71 hrs. until they developed into definitely fused embryos of heart-beat stage. In another *L. palustris* egg having 2 separate vitelli, the migratory movements of these vitelli were recorded, by projection, from the 2-cell stage through fusion to death, at 70 hrs. In *P. gyrina* eggs one primary blastomere survived destruction of the other by a glass needle, 167 hrs. Minute injury with the glass needle to a primary blastomere in another egg was followed by formation of only 3 micromeres, characteristic double segmentation cavity and death. Following injury or complete destruction of one primary blastomere, the other commonly survives 40-70 hrs. in *Lymnaea* and

Physa. Injury to a blastomere of 4-cell eggs resulted in death without further cleavage. Since the normally or experimentally fused, injured, or fragmented vitelli all died before reaching the hatching stage, and usually before the control egg, the writer concludes that the chances for monozygotic twinning to occur in these snails are very nearly nil.—*E. D. Crabb.*

11441. **GEORGE, W. C. The histology of the blood of some Bermuda ascidians.** *Jour. Morph. and Physiol.* 49(2): 385-413. 5 pl. 1930.—On the basis of studies with both the supravital technique and the section method, the structure of the blood cells is described for the following species of ascidians: *Phallusia nigra, Ecteinascidia turbinata, Clavelina oblongata*, and *Symplegma viride*. Subject to considerable variation in cytological detail, the following types of cells were found in all these species: (a) green cells, (b) orange cells (except in *C. oblongata*), (c) coarsely granular amoebocytes, (d) amoeboid compartment cells with or without colored or colorless granules in the vacuoles, (e) vesicular cells with or without colored or colorless granules, (f) small finely granular amoebocytes. Other evidence and the presence of what appear to be intermediate stages between the finely granular amoebocyte and the more specialized types of cells suggest that the finely granular amoebocyte is the parent cell or the cell most closely related to the common-stem cell.—*W. C. George.*

11442. **GRANDORI, R. Studi embriologici sulle razze polivoltine del bombice del gelso. [Embryological study on the polyvoltine race of silk-worms.]** *Atti R. Accad. Naz. Lincei Rend. Cl. Sci. Fis. Mat. e Nat.* 8(12): 717-722. 1 fig. 1928.—The embryonal streak (Keimstreifen) is much longer than in eggs of annual races. The yolk cells are less individualized than in the annual eggs. The bivoltine eggs are full of symbiotic organisms which are more numerous than in the annual eggs.—*M. Tirelli.*

11443. **KANAJEW, J. Zur Frage über die Wiederbildung der Fussscheibe bei Hydra.** *Zool. Anz.* 81(1/4): 89-93. 4 fig. 1929.—Regeneration of the basal disk of *Pelmatohydra oligactis* was studied in both apical and basal pieces that lacked interstitial cells. Normal and complete basal disks were formed. It is concluded that interstitial cells are not necessary for the regeneration of the basal disk, that both endodermal and ectodermal cells are involved in the process, and that the gland cells are derived from the ectoderm.—*J. W. Buchanan.*

11444. **KOCIAN, VOJ. Un cas d'hétéromorphose chez Argulus foliaceus L.** *Arch. Zool. Exp. et Gén. Notes et Rev.* 70(1): 23-27. 2 fig. 1930.—The regeneration of the amputated abdomen in a parasitic type took the form of "plurimorphosis," i.e., the appearance of supplementary organs which, while typical as to morphological structure, size, and physiological function, occupy an abnormal position. The portion regenerated bore 2 prs. of appendages, of which the 2nd pair, with numerous joints in the exopodite and the endopodite, shows an analogy with the furca of copepods from the functional viewpoint and even by its topographical position. Between the 2 prs. of regenerated appendages there developed a spherical organ which, from its topographical position and its chitinization, must be regarded as the regenerated ovary.—*W. M. Tattersall.*

11445. **KORSCHELT, E. Zur Frage der morphogenetischen Induktion nach Transplantation.** *Zeitschr. Wiss. Biol. Abt. D, Wilhelm Roux' Arch. Entwicklungsmech. Organ.* 117: 1-20. 6 fig. 1929.—The author states that the conception of the kind of influence active in transplantation experiments has undergone (especially in the last decade) an essential change since he considered the influence of the components in transplantations (1908). He reviews the results and interpretations recorded for transplantation experiments and cites the results of the experiments of Rutloff (1908) and of Leypoldt (1910) on several species of earthworm as entirely free from objections. In one a piece composed of segments 5-8 was reversed and segment 5 was attached to segment 5 of an anal portion; in the other a piece composed of segments 4-7 was reversed and segment 4 attached to segment 27 of an anal piece. A typical head developed at each end. "These results show that a practically normal head was developed at the anal end of the transplant and formed a unit both morphologically and physiologically with the reversed transplant and the recipient. It is noteworthy that the result is the same whether the union takes place near the head end or far behind it. Undoubtedly the host portion of the body had an especially effective influence in the completion of the body by overcoming the polarity in the regeneration of the head. The morphodynamic field, the action of which Mutschellor accepts, can at present be of little service in explaining these cases. An induction is observable but its nature is obscure. In this respect the results of these experiments on invertebrates coincide with the more thorough experiments on vertebrates."—*H. F. Nachtrieb.*

11446. **LUCAS, ALFRED M. The distribution of the branchial nerve in Mytilus edulis and its relation to the problem of nervous control of ciliary activity.** *Jour. Morph. and Physiol.* 51(1): 195-206. 1 pl. 1931.—The branchial nerve of *M. edulis*, traced by means of serial sections, is limited entirely to the epithelial and connective tissues bordering the axis of the gills. Most of its numerous branches extend posteriorly and lie close to the interfibrillar matrix of the connective tissue which supports the epithelium of this region. Fibers of these nerves have been traced to this epithelium. The chitinous supporting structures of the gills lie in close proximity to these nerves, yet neither nerves nor nerve fibers have been observed to penetrate them. Moreover, a careful study of the gill tissues fails to reveal the presence of structures which might be interpreted as nerves or nerve fibers. Since no innervation of the gills has been demonstrated, it seems probable that the ciliary activity of the gill epithelium is not regulated by means of fibers connected with the central nervous system.—*Author (courtesy Wistar Bibl. Serv.).*

11447. **MALOWITSCHKO, EUGENIE. Über entzündliche Entstehung des Bindegewebes bei Actinien.** *Virchow's Arch. Path. Anat. u. Physiol.* 280(2): 476-486. 8 fig. (4 col.) 1931.—Observations from ½ hr. to 70 days were made on actinians through which silk thread had been passed. The development of inflammatory connective tissue followed the same course as in higher animals. Migratory cells (at first eosinophils) capable of phagocytosis collected about the foreign body; blood is lacking in actinians, being replaced by intracellular fluid which was probably the source of most of the migratory cells which flow from the fissures between the epithelial cells toward the trauma. The eosinophils were engulfed at the injury and disintegrated. Later amebocytes surrounded the injury by a syncytium, intermingled with the silk thread, and gave rise to fibrous connective tissue. The process was slow and not ended in 70 days, for large numbers of amebocytes, united to uninterrupted symplasts, were present from which, by

analogy with other animals, collagen fibers and permanent connective tissue cells would be formed. The delay can be explained by continuous infection, among other things, since microorganisms (e.g., unicellular algae) were often found entering on the silk threads from the water.

11448. MASSAL, LOUIS-PIERRE. Recherches sur la formation du calcaire dans les glandes de Morren des Lombriciens. *Bull. Soc. Zool. France* 54: 46-61. 4 fig. 1929.—The author studied *Eisenia foetida, Allolobophora caliginosa*, and *Lumbricus herculeus*. The secretory epithelium of the glands consists of 3 regions: an anterior, transmissive only, containing mucous cells; a middle, secretory, the epithelial layer disintegrated at its free border, the interlamellar cavities filled with calcareous particles; and a posterior, where the epithelial layer is normally intact and there are no calcareous particles in the cavities. The nuclei of the secretory region are some basal, smaller, with denser chromatin, capable of amitotic division; and some near the free edge of the cells, which may be detached and thrown off along with a thin coating of cytoplasm. This is a normal process, the layer being renewed by the division of the deeper nuclei. There is no passage of nuclei from the interior of the blood-sinus into the secretory layer, as stated by Harrington. The chondriome is abundant, resistant, in the form of elongated rodlike chondrioconts disposed obliquely to the basal membrane. The protoplasmic layer near the free border of the cells is hyaline, without chondriome, and contains calcareous granules of various sizes, which appear in situ and have no relation to chondriome or nucleus. The vacuome consists of isolated vacuoles, fairly regularly distributed in the basal third of the layer, near the basal membrane. Golgi bodies were not discovered. The calcareous corpuscles, 5-8 μ in maximum diameter, are refringent spheroliths, consisting of a stroma probably derived from the protoplasm of the cells, in which are needles of calcium carbonate radially arranged; the form of the carbonate, known as vaterite, changes into calcite on exposure to water vapor at 50°; some transformation into calcite takes place in the gland, before the expulsion of the corpuscles into the oesophagus. The corpuscles are evacuated by antiperistaltic contractions of the muscular coat of the oesophagus, which envelops the glands. —*J. Stephenson.*

11449. MEYER, A. Urhautzelle, Hautbahn und plasmodiale Entwicklung der Larve von Neoechinorhynchus rutili (Acanthocephala). (Ein Beitrag zur Entwicklungsmechanik gebahnten Organbildung.) *Zool. Jahrb. Abt. Anat. u. Ontog. Tiere* 53(1): 103-126. 1 pl., 29 fig. 1931.—The polarity of the egg with the polar bodies on the vegetative pole coincides with the polarity of the egg of *Macracanthorhynchus hirudinaceus* (= *Gigantorhynchus gigas*), with the exception of a slight concentration of the protoplasm in the animal region in *N. rutili*. In the course of the cleavage, which follows in general the quadrant- and quartet-type, the posterior cell D differs from the other quadrants A, B and C owing to its protoplasmic density and proves to be a primary skin cell, i.e., the mother-cell of the whole skin of the trunk. Later on the descendants of the A, B and C-quadrant become plasmodial and give rise to the "embryonic nucleus"; the descendants of the primary skin cell, the skin-bahn, divide up to 6 nuclei and, after having become plasmodial, envelop the "embryonic nucleus" (plasmodial gastrulation). The development is traced up to a stage of 50 normal and 6 skin "cells" (nuclei) with the subsequent histological differentiation of the larva and the larval shells. This is, so far as is known, the first case of a cellular organ-bahn of a somatic organ. The difference from the eggs with organ-forming substances, e.g., *Styela*, is given in the fact, that in *N. rutili* the skin-forming plasma of the egg separates as an individual cell (D) from the remaining part of the embryo and takes its course separately. —*H. Heath.*

11450. PIERANTONI, UMBERTO. Origine e sviluppo degli organi simbiotici di Orizaephilus (Silvanus) surinamensis L. [Origin and development of the symbiotic organ of O. surinamensis.] *Rend. Accad. Sci. Fis. e Mat. Cl. Soc. R. Napoli* 36(7/12): 141. 1930(1931).—Abstract.

11451. PORTMANN, ADOLF. Dedifferenzierung bei Seeanemonen und ihre Bedeutung für das Problem der Axialgradienten. *Rev. Suisse Zool.* 34(2): 161-164. 1927. —In 1/10,000 to 1/30,000 KCN the sea anemone *Aiptasia carnea* disintegrates beginning at the tips of the tentacles, proceeding to their bases, and then involving the oral disk, until only body wall and pedal disk remain. If returned to sea-water in this condition, complete regeneration occurs. Histological study shows that disintegration begins in the ectoderm; the gland cells and supporting cells become amoeboid and phagocytic. The ectoderm is more susceptible than the entoderm everywhere, in respect to both epithelial and muscular elements. Similar histological changes occur in the pedal disk although these are not evident by gross inspection. The effect aborally is therefore much greater as shown by histological inspection than would be suspected from macroscopic examination. The esophagus is very resistant although it is an oral structure. In the septa the walls are more susceptible than the mesenterial filament. Thus while macroscopically there appears to be a regular antero-posterior disintegration, histologically the KCN is seen to affect certain tissues and organs, no matter where they occur with reference to the axis, more than others. The author suggests that disintegration studies should be accompanied by histological examination.—*L. H. Hyman.*

11452. WINTREBERT, P. Les courants plasmiques corticaux décelés par les figurations pigmentaires à la surface de l'oeuf fécondé indivis de Discoglossus pictus Otth. *Compt. Rend. Soc. Biol.* [*Paris*] 106(10): 784-788. 6 fig. 1931.—One to 3 hrs. after fertilization the dorsal surface of the egg shows pigmented striations radiating outwards from the animal pole, chiefly toward the dorsal side. These rays result from currents of cortical plasm which flow toward the animal pole and carry grains of pigment with them. The flow ventrally and laterally is checked in part by the sperm aster. The resulting pattern is complicated by an accompanying rotation of the egg downward on the ventral side.—*F. G. Gilchrist.*

11453. SHULL, A. FRANKLIN. Order of embryonic segregation in intermediate aphids not reversed by low temperature. *Amer. Naturalist* 65(700): 469-473. 1931. —Previous experiments have shown that aphids (*Macrosiphum solanifolii*), intermediate between parthenogenetic and gamic, possess the same characteristics regardless of the direction of the change in which the intermediates were produced. If the intermediates owe their composition to the order in which their differential structures are embryonically determined, that composition should be different for the 2 directions of approach to the intermediate condition. One of 3 suggested explanations of the identity of the 2 classes of intermediates, referred to above, was that the high and low temperatures used to induce opposite changes had also caused reversed orders of embryonic determination. Now, however, a considerable number of intermediates demonstrate a close correlation between the time of determination of wings and the time of determination of hind tibiae. Wings had been previously shown to be determined late, hence tibiae must also be determined late. Since these intermediates were obtained at low temp., the hind tibiae should, if low temp. reversed the order of determination, have been determined early. Apparently, therefore, low temp. did not reverse the order of determination.—*A. F. Shull.*

11454. UBISCH, L. von. Über die Determination der larvalen Organe und der Imaginalanlage bei Seeigeln. *Zeitschr. Wiss. Biol. Abt. D, Wilhelm Roux' Arch. Entwicklungsmech. Organ.* 117: 80-122. 40 fig. 1929.—"(1) Germs of *Echinocyamus pusillus* in the 8-cell stage were divided equatorially. The animal half developed

into a blastula only, but the vegetative half gastrulated and developed into a small pluteus. (2) Germs placed in a Li solution after fertilization, divided equatorially at the 8-cell stage and were left in the solution to the blastula stage: (a) Animal half: After the addition of 2% of a 3.7% solution of Li to the water the animal half did not develop beyond the blastula; after addition of 3% of the solution there was typical formation of entoderm but no invagination; after addition of 3.5% typical gastrulae were formed; after addition of 4% the animal halves died at or before the blastula stage. (b) Vegetative halves: After addition of 2% of a 3% sol. of Li these halves gastrulated but were much more perishable than those developed in normal sea water or those that had been separated in the blastula stage; after addition of 3.5% of the sol. these halves at best reached only the stage of the mesenchyme blastula; after addition of 4% of Li sol. only the blastula stage was reached. (3) Embryos of 8 cells were divided equatorially and then placed in the Li sol. up to the blastula stage: (a) After addition of 3% of the Li sol. about ¼ of the animal halves gastrulated and after the addition of 3.5% of the sol. about ⅔; these gastrulae could develop into plutei with larval processes, mouth, and skeleton. (b) The vegetative halves could reach the blastula stage. In general they developed better than those halves which had been in the Li sol. before the operation. (4) The facts of 3a show that the formation of entoderm and gastrulation may occur without the influence of a possible local organization center in the vegetative half of the complete germ. (5) In Ca-free sea water the 8 mesomeres of the 16-cell stage arranged in 2 rings of 4 each. Vital staining shows that the 4 near the animal pole develop the zone of the ciliary tuft. If this zone is removed in the 16-cell stage the remaining ¾ develops into an harmonious pluteus. Evidently part of the presumptive entomesoderm becomes differentiated into ectoderm. (6) Runnström's hypothesis that the ciliated-tuftzone contains an entoderm-limiting center is not confirmed. (7) Amphibian and sea urchin germs agree in that morphologically and physiologically distinguishable zones can be determined in the unsegmented egg. Germ layer determination is a result of self-differentiation. (8) The observations of Hörstadius can not be used in support of the view that the determination of germ layers, of gastrulation and of the larval organs in the sea urchins is influenced by an organization center in the vegetative half. (9) Organizer and wholefactor (Ganzfaktor) are not identical, rather operate antagonistically. Organization center and regulation center are not identical concepts. Regulation by the "whole-factor" can be restricted through the counteraction of organizers, the absolute or relative want of an organ-forming germ substance of specific nature. (10) There is no reason for the hypothesis that the formerly most vegetative portion of the sea urchin germ acts as an organization center after the division of the germ. (11) After the conclusion of gastrulation in the sea urchins: (a) The foregut in all probability has an inducing influence on the formation of the mouth. (b) Primary mesenchyme and ectoderm influence each other in their formation. (c) The hydrocoele induces the formation of the neural anlage, in the proper or wrong position. (12) After gastrulation the development of amphibia and sea urchins is similar in that:—The entomesoderm underlies the ectoderm. The median portion of the entomesoderm particularly induces formation of the neural system. The development and relative position of the gut, coelom, chorda, neural tube, epidermis are decidedly similar. The hydrocoele of the sea urchin fills out the place of the chorda."—*Author's summary (transl. by H. F. Nachtrieb).*

Exp. et Gén.* 71(3): 317-331. 9 fig. 1931.—**SPHALLOPLANA** (p. 321), based on *S.* percaeca* (*Dendrocoelum percaecum* Packard) (p. 321), redescribed, anatomically and histologically, from specimens from Mammoth Cave, Kentucky.

11456. CARTER, J. S. Observations on Rhabdocoeles of Albemarle County, Virginia. *Trans. Amer. Microsc. Soc.* 48(4): 431-437. 1929.—A list of 15 genera of rhabdocoeles found in the neighborhood of the Univ. of Virginia, is given. Detailed observations have been made upon 5 representative spp. *Stenostomum leucops* was fond to survive egg-laying, contrary to the observations of previous workers. Observations upon *Microstomum* led to agreement with Gamble that this genus is dioecious. The presence of gonads retards but does not inhibit fission. *Prorhynchus applanatus* may be either protandrous or protogenous. This form also displays polyembryony. It displays a regeneration-power, but not that of fission. *Rhynchomesostoma rostratum* appears in cycles and the members of each cycle vary greatly depending upon the food supply. *Phaenocora agassizi* is capable of either self-fertilization or of parthenogenetic development. It produces summer and winter eggs.—*W. A. Kepner.*

Thirty-six species are reported, and notes on their morphology and distribution are given.

11470. **BENNETTS, H. W.** The helminths of Western Australian stock. Recorded and unrecorded species. *Jour. Roy. Soc. Western Australia* 13: 49-60. 4 fig. 1926-1927 (1928).—Previous lists were given by Sweet (1908) and by Filmer (1926). The author gives the following additional records: *Choanotaenia infundibuliformis* and *Davainea* sp. from fowl; *Dipylidium caninum* from dog; *Trichuris suis* from pig; *Strongylus equinus*, *S. edentatus*, *S. vulgaris*, *Trichonema longibursatum**, and *T. tetracanthum** from horse; *Ostertagia ostertagi* from heifer; *Ostertagia* sp. from sheep; *Oxyuris equi* from horse; *Toxocara canis* from dog; *Ascaridia lineata** and *Heterakis vesicularis* from fowl; *Habronema microstoma*, *H. muscae*, and *Onchocerca** sp., from horse.

11471. **BENNETTS, H. W.** Further contributions to the helminths of Western Australian stock. *Jour. Roy. Soc. Western Australia* 14: 57-59. 1927-1928 (1928).—The author records *Davainea echinobothridia* from fowl; *Anoplocephala perfoliata*, *Triodontophorus brevicauda*, *T. minor*, *Trichonema poculatum*, and *Gyalocephalus* sp. from horse; *Oesophagostomum venulosum* from sheep; and *Onchocerca cervicalis* from horse. Most of these appear to be new records for Australia.

11472. **BOULENGER, C. L.** Report on a collection of parasitic nematodes, mainly from Egypt. Part IV. Trichostrongylidae and Strongylidae. *Parasitology* 18 (1): 86-100. 28 fig. 1926.—Parts I-III of the reports on the Molteno Inst. coll. dealt with Ascaridae, Heterakidae, Oxyuridae, Camallanidae, etc. The present installment gives descriptions of new spp., notes on other forms, and a list of determinations of material. *Histiostrongylus* **spinosus*** (p. 88) from intestine of *Taphozous perforatus*; note on *H. paradoxus* from the small intestine of bat; *Epomidiostomum* **querquetulae*** (p. 91) from stomach-wall of *Querquetula crecca*; *Amidostomum* **skrjabini*** (p. 94) from *Vanellus cristatus*; **PSEUDAMIDOSTOMUM** (p. 95), erected for *P.* **loossi*** (p. 96) from stomach-wall of *Fulica atra*.

11473. **BRUG, S. L.** Filaria malayi n. sp., parasitic in man in the Malay Archipelago. *Far East. Assoc. Trop. Med. Trans. 7th Cong. Brit. India* 3: 279-298. 1 pl., 7 fig. 1927 [1928].—*Filaria* **malayi*** (p. 281), microfilaria from blood; adults not described.

11474. **COBB, N. A.** Ungella secta n. gen., n. sp.; a nemic parasite of the Burmese oligochaete (earthworm),

Eutyphoeus rarus. *Jour. Washington Acad. Sci.* 18(7): 197-200. 4 fig. 1928.—**UNGELLA** (p. 197), resembling *Diplogaster,* type *U.* secta* (p. 197).

11475. **COBB, N. A., and G. STEINER.** [Need for a more careful and intensive study of certain Aphelenchi.] *Jour. Parasitol.* 14(1): 68. 1927.

11476. **[KULAGIN, N. M.]** КУЛАГИН, Н. М. К биологии пшеничной угрицы (Tylenchus scandens Schn.). [A note on the biology of T. scandens.] Доклады Академии Наук СССР. (*Compt. Rend. Acad. Sci. URSS.*) A. No. 2: 35-36. 1928.—*T. scandens* lives only in the galls which it produces in the pistils of wheat. Galls placed in the earth in the fall gave rise to young worms in the spring, the temperature of the soil being at that time 10° C. Galls covered with water and kept at room temp. gave off young worms in 2½ months; placed in moist soil, under the same conditions, they produced young worms in 3½ months. There is no change in the anatomy of dried-up worms, save for some shrinkage of tissue. The worms, dried by degrees, are able to survive 88° C., but wet, they die at 50° C. in 15-20 min. Successive drying and reviving 6 to 8 times during 6 days, kills the worms. Worms from dried-up galls live longer than those from the watered galls. The worms reach the leaves by way of the stem of the plant or directly from the air.—*D. Sinitsin.*

11477. **LIEBERMANN, ANTONIA.** Die freilebenden Nematoden der Flussbingen der Moldau bei Bráník. *Internat. Rev. Ges. Hydrobiol. u. Hydrograph.* 20(5/6): 409-429. 6 fig. 1928.—Studies of the nematode fauna and its annual cycle, are reported for the region. An annotated descriptive list of the spp. taken is presented. *Dorylaimus* corii* (p. 420), is new.

11478. **MAN, J. G. de.** Das Männchen der Rhabditis monhystera Bütschli. *Zool. Anz.* 70(1/2): 51-57. 5 fig. 1927.—Diseased spots on potato roots from Wijkbij Duurstede, were found to contain *Tylenchus dipsaci* (Kühn) in great numbers and, in addition, numerous individuals of a sp. of *Cephalobus* (probably *C. rigidus* A. Schneider) and of *Rhabditis monhystera* Bütschli. The last named consisted of both ♂♂ and ♀♀. That these are the true ♂♂ of *R. monhystera* is shown by the fact that no other sp. of *Rhabditis* was present, and by the close morphological resemblance of these ♂♂ to the ♀♀. It is concluded that *R. monohystera* as used by Cobb, A. Tysowski, and A. Schneider, and *R. simplex* of Cobb, are not the same as *R. monhystera* Bütschli. *R. monohystera* of A. Schneider is believed to be *R. teres* (A. Schneider).—*J. R. Christie.*

11479. **MAN, J. G. de.** Sur quatre espèces de Nématodes libres observées aux environs de Caen dans un canal d'eau saumâtre à Quistreham. *Bull. Soc. Zool. France* 53: 96-103. 1 pl. 1928.—*Theristus acer, Axonolaimus** sp., *Adoncholaimus thalassophygas,* and *Chromadora viridis* are recorded, with morphological notes.

11480. **MÜLLER, JUSTUS F.** The cuticula of the Nemathelminthes. *Jour. Parasitol.* 14(2): 131. 1927.—Abstract.

11481. **PETROW, A. M.** Addition to the explanation of systematics of nematodes parasitic in the frontal sinus and lungs of Mustelidae. *Ann. Trop. Med. and Parasitol.* [*Liverpool*] 22(2): 259-264. 2 fig. 1928.—Descriptive and historical notes are given, to permit the differentiation of *Filaroides bronchialis** and *Skrjabingylus nasicola**.

11482. **STEINER, G.** The nemic population of the soil. *Proc. First Int. Congress Soil Science* 3: 360-366. [1927] 1928.—A general discussion.

11483. **ŠVÁBENÍK, JAN.** Aus dem Leben der Paramermis contorta (v. Linstow). *Zool. Anz.* 77(9/10): 259-267. 4 fig. 1928.—During winter and spring about 30% of the larvae of *Chironomus thummi* were found infected with *Paramermis contorta.* When fully grown the parasites force their way out near the posterior end of the host, usually through the anal foot. Molting, copulation, and egg laying follow immediately. Eggs hatch after a developmental period of 4-30 days, depending on the temperature. When placed in cultures of mud and water, larvae will live 18-20 days after hatching. They bore their way into young *Chironomus* larvae, the anal foot being a favored point of entrance. They rarely enter old *Chironomus* larvae. Should the host die 2 days after the parasites enter, the latter will emerge from the dead body and are capable of infecting a second host. In one case a *P. contorta* larva was observed to molt simultaneously with its entrance, leaving the shed cuticle attached to the outside of the host. A molt takes place about 10 days after entering. The parasitic development is completed before the host pupates; in only 2 cases were *Chironomus* pupae found infected.—*J. R. Christie.*

11484. **THIEL, P. H. van.** On some Filariae parasitic in Surinam mammals, with description of Filariopsis asper n. g., n. sp. *Parasitology* 18(1): 128-136. 17 fig. 1926.—In the present paper the term Filaria is used in its widest sense. Descriptions are given of forms parasitic in monkey, tiger-cat, and "pakira," collected by C. Bonne in Surinam. **FILARIOPSIS** (p. 129), type *F.* asper* (p. 129), from the lungs of a "roaring-monkey," *Mycetes seniculus.* Also *Filaria gracilis** Rud. from the peritoneal cavity of a sp. of *Cebus, F. acutiuscula** Molin from the subcutaneous tissue of the "pakira," *Dicotyles torquatus,* and *F. striata** Molin from the subcutaneous tissue of *Felis pardalis,* are redescribed.

11485. **VOGEL, H.** Beiträge zur Anatomie der Gattungen Dirofilaria und Loa. *Centralbl. Bakt. etc. Abt. 1. Originale* 102(1/3): 81-89. 2 pl. 1927.—A morphological study of *Dirofilaria immitis* and *D. repens.* The only distinguishing differences found between these 2 spp. are the structure of the spicula and the form, number, and arrangement of the ♂ papillae. Filarids from a South American monkey, *Ateles paniscus,* proved to be a South American variety of the African *Loa papionis,* here designated as *L. p.* var. st. pauli*.—*J. R. Christie.*

11487. **ANNENKOVA, N.** Beiträge zur Kenntnis der Polychaeten-Fauna der USSR. [Contributions to a knowledge of the polychaete fauna of the USSR. I. Pectinariidae and Ampharetidae.] Ежегодник Зоологического Музея Академии Наук Ленинград (*Ann. Mus. Zool. Acad. Sci. Leningrad URSS.*) 30(3): 477-500. 1929.—This paper is based upon extensive material in the Zool. Mus. Acad. Sciences, Leningrad, including

the collections of various expeditions to the Arctic and Pacific Oceans and the Caspian, Black, and Azov Seas. There is an account of 26 forms, with synonymy, locality records, and taxonomic discussion. *Pectinaria* (*Amphictene*) moorei* (p. 482), east coast of Siberia, 132-159. 7 m.; *P.* (*Cistenides*) soldatovi* (p. 486), Japan and Ochotsk Seas, 26-62 m.; *Ampharete goësi* ssp. bražnikovi* (p. 492), Ochotsk Sea, 21.3-25.5 m.; *A.* crassiseta* (p. 493), Ochotsk Sea, 17.6-21.3 m.; **ASABELLIDES** (p. 494) erected for *A.* orientalis* (p. 494), Ochotsk and Japan Seas, 32-55 m.; *Amphicteis* mederi* (p. 499), Ochotsk Sea, 372.7 m.

11488. **BERE, RUBY.** Leeches from the lakes of northeastern Wisconsin. *Trans. Wisconsin Acad. Sci. Arts and Lett.* 26: 437-440. 1931.—A list of 11 Glossiphonidae, 2 Ichthyobdellidae, 2 Hirudinidae, 4 Erpobdellidae. *Placobdella rugosa* was taken on human beings, and on the blue gill sunfish; *P. montifera* on yellow perch and rock bass; *P. pediculata* on the sucker; *Piscicola punctata* on yellow perch, small-mouthed black bass, and blue gill.

11490. **ČERNOSVITOV, L.** Note sur les Oligochètes des grottes de Sante-Reine près de Toul. *Arch. Zool. Exp. et Gén., Notes et Rev.* 71(2): 62-66. 6 fig. 1931.—A record of *Eiseniella tetraedra* and a detailed study of *Enchytraeus buchholzi**.

11491. **ČERNOSVITOV, L.** Eine neue Lumbricus-Art aus der Umgebung von Prag. *Zool. Anz.* 96(7/8): 201-204. 2 fig. 1931.—*Lumbricus* bohemicus* (p. 201), Bohemia, is compared in tabulation with 9 other spp.

11492. **HARDING, W. A.** Hirudinea. Part 21 of Results of an expedition to Korinchi Peak, 12,400 ft., Sumatra. *Jour. Fed. Malay States Mus.* 8(3): 221-225. 2 fig. 1931.—**ACRABDELLA** (p. 222) (Erpobdellidae), type *A.* sumatrensis* (p. 222).

11493. **MONRO, C. C. A.** On a collection of Polychaeta in the Raffles Museum, Singapore. *Bull. Raffles Mus.*, 5. [33]-[46]. 12 fig. 1931.—A report on 16 spp., chiefly from the vicinity of Singapore; a few are from the Malay Arch. and the China Sea. The systematic account includes references to the literature, distributional records, and descriptive and taxonomic notes. The heteronereids of *Perinereis singaporiensis**, *P. nancaurica**, and *P. cultrifera* v. perspicillata* (*P. p.* Grube) (p. 41) are described for the first time. The range of *Pseudonereis variegata* is extended from the Atlantic Ocean to the China Sea.

11494. **MOSZYŃSKI, A.** Répartition quantitative des Enchytraeidae dans différents milieux. *Ann. Mus. Zool. Polonici* 9(7): 65-125. 1930.—The depth at which Enchytraeidae are found depends upon soil properties and, to a certain degree, on the size of the worms. Their distribution is very unequal and varies even within the space of a dm. The density of population varies from 0 to 1000 and their volume from 0 to 600 mm.^{3} per dm.^{3}; the relation of total volume of animals to soil volume may be as high as 1: 1000 under optimum conditions, with a mean of 1: 5000-1: 20000. Most species have the ability of adapting themselves to widely varying conditions, a change from one medium to another being characterized by a quantitative rather than a qualitative change in fauna. In brackish media not directly influenced by the sea the population is generally the same as in ordinary environments, but in brackish soils directly influenced by sea water the population is greater and its qualitative composition quite different. *Pachydrilus* is found only in brackish media. *Enchytraeus albidus* is ubiquitous.—*A. Moszyński* (*transl. by A. O. Weese*).

11495. **TREADWELL, A. L.** New species of polychaetous annelids from California, Mexico, Porto Rico and Jamaica. *Amer. Mus. Novitates* 482. 1-17. 22 fig. 1931.—*Lumbrinereis* singularisetis* (p. 1), California; *Oenone* brevimaxillata* (p. 1), Mexico; *Hipponoe* elongata* (p. 3), Porto Rico; *Nainereis* mutilata* (p. 5) and *Goniada* teres* (p. 6), Jamaica. Types in Amer. Mus. Nat. Hist. *Nereis* largoensis (*N. brevicirrata* Treadwell, preocc.) (p. 3); *Scoloplos* cirrata (*Aricia c.* Treadwell) (p. 4).—*A. L. Treadwell.*

11496. **UDE, H.** Oligochaeta. In: **Friedrich Dahl's** Die Tierwelt Deutschlands Teil 15. 1-132. 165 fig. Gustav Fischer: Jena, 1929.—A brief account of the morphology, propagation, mode of life and nutrition, with keys to the families, genera, and species of German Oligochaeta; synonymy, diagnostic descriptions and geographical distribution of species. Supplement gives descriptions of foreign species occurring in Germany. Systematic index and bibliography are included.—*G. E. Pickford.*

ECHINODERMATA

HUBERT LYMAN CLARK, *Editor*

(See also in this issue Entries 11243, 11244, 11248, 11251, 11255, 11258, 11261, 11526)

11497. **DAVIES, L. M.** Remarks on the known Indian species of Conoclypeus, with descriptions of two new species from the Eocene of North-West India. *Rec. Geol. Surv. India* 59(3): 358-368. 2 pl. 1926.—*C.* pilgrimi* (p. 359), Alveolina Limestone level of the Indian Laki series, and *C.* warthi* (p. 363), probably from the same horizon. Types in Geol. Surv. India.

11498. **HEROUARD, EDGARD.** Holothuries de la côte Atlantique du Maroc et de Mauritanie. *Bull. Soc. Sci. Nat. Maroc* 9(1/6): 36-70. 1 pl., 5 fig. 1929.—Notes on 21 spp., including *Cucumaria* mauritanica* (p. 38), Mauritania; *C. koellikeri**; *C. elongata**; **HEMIOEDEMA** (p. 45), (Cucumariidae), near *Thyone,* type *H.* gruveli* (p. 45); *Holothuria arguensis**; *Mesothuria verrilli**; and *Epitomapta roseola**. The bibliography contains 61 references.

11499. **JAKOVLEV, N.** Notes sur les Crinoïdes paléozoïques. Известия Академии Наук СССР., Отделение Физико-Математических Наук (*Bull. Acad. Sci. URSS., Cl. Sci. Phys.-Math.*) 1930(9): 907-912. 1 pl., 1 fig. 1930.—*Hexacrinus,* new diagnosis; *H. patereformis**, additional description; *Monobrachiocrinus* siciliensis* (p. 909) and *Agassizocrinus* (?) striatiferus* (p. 909), both Sicily, Permian, and types in Univ. of Padua; *Allagecrinus* donetzensis* (p. 910), Ukrainia.

11500. **JOHNSON, MARTIN W.** Notes on the larval development of Strongylocentrotus franciscanus. *Publ. Puget Sound Biol. Sta.* 7: 401-411. 2 pl. 1930.—Eggs were fertilized and cultured in dishes kept cool by running water in the laboratory. The larvae were kept alive and studied for 62 days. In structure the larvae were characteristic of those of the family Echinidae. The body rods were club shaped, recurrent rods were present, but no posterior transverse rods appeared. Both anterior and posterior ciliated epaulettes were developed. Metamorphosis was begun in about 28 days, and was not complete at 62 days. Diatoms were utilized as food for the larvae.—*M. W. Johnson.*

11501. **LAMBERT, JULES, y MARIO SÁNCHEZ ROIG.** Nuevas especies de equinodermos fosiles Cubanos. [New spp. of Cuban fossil echinoderms.] *Mem. Trab. Realiz. Inst. Nacion. Invest. Cien. y Mus. Hist. Nat.* [*Habana*] 1: 141-150. 2 pl. 1929(1930).—*Leiocidaris* cojimarensis* (p. 144), Miocene; *Amblypygus* douvillei* (p. 145), Lower Oligocene; *Progonolampas* sanchezi* Lambert (p. 148), Miocene; *Brissoides* stefaninii* (p. 148), Oligocene; *Echinodiscus* crustuloides (*Scutella c.* Morton) (p. 144). The genera *Amblypygus, Progonolampas,* and *Echinodiscus* are new to Cuba.

11502. **MERCIER, JEAN.** Note sur un radiole de Cidaris calloviensis Cot. parasité. *Bull. Soc. Linn. Normandie* 1: 16-17. 1928(1929).—A radial was found in the Callovian in a quarry in Orne, France. It was deformed by a gall caused by a sp. of myzostomous worm.

11503. MERCIER, JEAN. Notes échinologiques. III. *Bull. Soc. Linn. Normandie* 1: 76-77. 1928 (1929).—Data on *Polycyphus normannus, P. jauberti,* and *P. corallinus.*

11504. MERCIER, JEAN. Notes échinologiques. VII. Sur quelques Echinides rares du Bathonien de Normandie. *Bull. Soc. Linn. Normandie* 3: 46-48. 1930 (1931).—The following are recorded as new to the Bathonian of the western Paris Basin: *Plegiocidaris briconensis, Paracidaris babeaui, Pseudocidaris drogiaca, Acrosalenia pulchella, A. berthelini, Pseudopedina bakeri, Polycyphus textilis,* and *Pygaster peroni.*

11505. MERCIER, JEAN. Notes échinologiques. VIII. Rhabdocidaris bigoti (Cidaridae, Stereocidaridae, Rhabdocidarinae), espèce nouvelle du Bathonien supérieur de la Sarthe. *Bull. Soc. Linn. Normandie* 3: Trav. Orig. 94-97. 1 fig. 1930 (1931).—*Rhabdocidaris* bigoti* (p. 94), from ferrugineous oolith of Upper Bathonian at Saint-Benoît (Sarthe), France.

11506. MORTENSEN, TH. On the postlarval development of some cidarids. *Kgl. Danske Vidensk. Selsk. Skrifter Naturvidensk. og Math. Afd. Scr. 8.* 11(5): 367-387. 21 fig. 1927.—A series of very young specimens of *Eucidaris metularia**, living in clusters of *Acanthogorgia* sp. in association with small crustaceans, worms, mollusks, and echinoderms, was obtained from Banda Is., East Indies, by a diver. The author considers that a study of the corona and peristome proves definitely "that the interradial plates of the peristome in cidarids have nothing to do with the interambulacral plates of the corona, but represent a new element, corresponding to the irregular plates occurring in varying number on the peristome of most regular echinoids." Indication of a supposed bothriocidarid ancestry is not clear. Curiously, the pore of the madreporite is not discernible in the younger stages. The supposed existence of a single, primary, large anal plate covering the whole periproct is disproved. Both primary and secondary spines are quite different in appearance from those of the adult. They do not develop into the adult form, but are either lost or resorbed as the plates bearing them are resorbed at the peristomal edge or pass into the peristome. The plates that develop later bear spines of the more advanced type. The pedicellariae are of the adult type, and suggest that transformation in their shape probably never takes place, any change being in the nature of a replacement. An embryonic stage of *Goniocidaris umbraculum** from New Zealand is described, as well as a young stage of *Aporocidaris milleri* from the "Panamic Deep Sea Expedition, 1891" of the "Albatross."

11507. RAVN, J. P. J. De irregulaere Echinider i Danmarks kridtaflejringer. [Irregular Echini of Denmark's chalk beds.] *Kgl. Danske Videnskab. Selsk. Skrifter, Naturvidensk. og Math. Afd. Ser. 8.* 11(4): 307-355. 5 pl., 5 fig. 1927.—A list, with descriptions of the 29 spp. (13 genera), including: *Pseudopyrina* subovalis* (p. 319), *P.* subcircularis* (p. 321), *Cassidulus* faberi* (p. 327), *Galeaster* carinatus* (p. 342), and *Cyclaster* brünnichi* (p. 345), all from the Danian series. Keys are given to genera and spp.

MOLLUSCA

H. B. BAKER, *Associate Editor*

J. B. REESIDE, *Associate Editor,* Mesozoic and Paleozoic Mollusca

(See also in this issue Entries 9074, 9181, 9385, 9386, 9453, 9702, 11222, 11243, 11244, 11245, 11246, 11247, 11250, 11251, 11252, 11253, 11255, 11256, 11257, 11258, 11259, 11260, 11262, 11438, 11446, 11581, 11599)

11508. ABRARD, RENÉ. L'equivalent de la zone à Streblites tenuilobatus dans l'est du bassin de Paris. *Bull. Mus. Nation. Hist. Nat.* [*Paris*] 1(2): 166-170. 1929.—The author remarks on 2 zones of the Kimeridgian (Jurassic), the lower characterized by *Streblites tenuilobatus* and the upper by *Aulacostephanus pseudomutabilis.* Characteristic species found in these beds in Haute-Marne, Meuse, and Ardennes are listed. The *Streblites* zone is associated with the Pterocerian, and the presence of *Pterocera* dates this deposit.

11509. BARTSCH, PAUL. A new shipworm from Venezuela. *Proc. U. S. Nation. Mus.* 79(8): 1-3. 1 pl. 1931.—Description of *Teredo* (*Neoteredo*) healdi* (p. 2) which becomes the 3rd species in this subgenus; type in U. S. Nat. Mus. Emended description is given of *T.* (*N.*) *miroflora* Bartsch.

11510. BARTSCH, PAUL. A new pearl oyster from the Hawaiian Islands. *Proc. U. S. Nation. Mus.* 79(12): 1-2. 2 pl. 1931.—*Pinctada* galtsoffi* (p. 1), type in U. S. Nat. Mus.

11511. BARTSCH, PAUL. Further explorations for mollusks in the West Indies. *Smithsonian Inst., Explorations and Field-Work of the Smithsonian Inst. in 1930. Publ.* 3111. 91-102. 4 pl. 1931.—Account of a cruise among the southern Bahamas and the islands off the south coast of Cuba, with general notes on mollusks and other forms of animal life met with.

11512. CORSIN, PAUL. Découverte d'une goniatite dans les schistes rouges de Fiennes (Boulonnais). *Ann. Soc. Geol. du Nord* 53: 283-286. 2 fig. 1928.—Discusses the finding of *Gephyroceras intumescens* Beyrich in the Devonian of Boulonnais, northern France.—*W. Berry.*

11513. COX, L. R. New lamellibranch genera from the Tethyan Eocene. *Proc. Malac. Soc. London* 19(4): 177-187. 2 pl. 2 fig. 1931.—Vulsellidae: **EUPHENAX** (p. 177), type *E.* jamaicensis* (*Pseudoheligmus* (?) *j.* Trechmann) (p. 178), from Jamaica. Veneridae?: **BLAGRAVEIA** (p. 183), type *B.* corrugata* (p. 184), from Sind, India.—*H. B. Baker.*

11514. DAUTZENBERG, PH., et **G. DOLLFUS.** Les planches de coquilles du R. P. Barrelier. *Jour. de Conch.* 74(4): 297-307. 6 pl. 1931.—These reproduced plates were prepared by the French naturalist, Jacques Barrelier (1606-1675) and were first published in 1714 by Jussieu. The authors discuss the species represented in the figures, many of which were cited by Linné.—*H. B. Baker.*

11515. DEHÉE, RENÉ. Observations sur les rudistes des terrains crétacés du nord de la France. *Ann. Soc. Geol. du Nord* 52: 36-50. 1 pl. 2 fig. 1927.—Five rudistids are described including *Durania cornupastoris* v. godoni* (p. 44), from the Turonian. A table shows the stratigraphic position of the rudistids in the region.—*W. Berry.*

11516. GASCHOTT, OTTO. Bemerkungen über einige Mollusken der Südalpenseen. *Arch. Molluskenk.* 63(1): 28-39. 1931.—A topical list of mollusks from lakes in south Alps.

11517. GEYER, D. Kurze Mitteilung. *Arch. Molluskenk.* 63(2): 92. 1931.—Winter-killed *Helix aspersa.*—*H. B. Baker.*

11518. GEYER, DAVID. Schnecken in Not. *Arch. Molluskenk.* 63(3): 129-131. 1931.—*Limnaea stagnalis* in ponds choked by vegetation becomes amphibious.—*H. B. Baker.*

11519. I[REDALE], T. The Waterhouse collections. Shells. *Australian Mus. Mag.* 4(4): 113-114. 1930.—An account of a fine collection of Mollusca presented by Mrs. M. J. Waterhouse to the Australian Mus.

11520. JOLEAUD, L. Transport par le vent de coquilles de Céphalopodes (Spirules) sur les côtes du Maroc. *Compt. Rend. Som. Soc. Biogéogr.* 61. 3-4. 1931.—The author reports shells of *Spirula* transported by wind for 100 meters from the shore, and cautions

geologists as to drawing conclusions from the association of such shells with those of terrestrial mollusks.

11521. **KIMAKOWICZ, RICHARD von. Alopia-Sammelreise 1930.** *Arch. Molluskenk.* 63(1): 39-42. 1 pl. 1931.—*Alopia* **mariae*** (p. 40), *A.* **hildegardae*** (p. 41), *A.* **occulta*** (p. 41), and *A.* **fortunata*** (p. 42), are described from Rumania.—*H. B. Baker.*

11522. **KINOSHITA, T., and S. KINOSHITA. On some muricid shells as enemies to the oyster.** [In Japanese.] *The Venus [Japan]* 2(4): 190-198. 19 fig. 1931.

11523. **LAIDLAW, F. F. On a new sub-family** Dyakiinae of the Zonitidae. *Proc. Malac. Soc. London* 19(4): 190-201. 6 fig. 1931.—**DYAKIINAE** is proposed for the following genera: *Dyakia,* including *D.* **godwinausteni** (p. 191), founded on Godwin-Austen's *D. striata* (Gray) var. from Siam, and *D. hugonis* (anatomical notes); *Staffordia;* **KALAMANTANIA** (p. 193), type *K.* **whiteheadi*** (*Helicarion* (?) *w.* Godwin-Austen), from Borneo (anatomical notes); and *Everettia,* including *E. subconsul** (anatomical notes).—*H. B. Baker.*

11524. **McLELLAN, ROY DAVIDSON. The geology of the San Juan Islands.** *Univ. Washington Publ. Geology* 2: 1-185. Map. 22 pl., 10 fig. 1927.—Lists the existing species of plants of these Pacific coast islands; describes the ammonoids, *Holcodiscus??* **stantoni*** (p. 115), and *Phylloceras* **spiedenensis*** (p. 116), and the pelecypods *Pleuromya* **thor*** (p. 116), *P.* **typa*** (p. 117), and *Lima* **spiedenensis*** (p. 117) from Lr. Cretaceous beds of Spieden Is.; the new gastropods, **CONDONELLA** (p. 131) resembling the fresh water *Planorbis,* with *C.* **suciensis*** (p. 131), type in U. S. Nation. Mus., and the pelecypods *Glycimeris* **suciensis*** (p. 131) and *Cucullaea* **suciensis*** (p. 132) from Up. Cretaceous beds of Sucia Isl. Types in Univ. Washington Paleontological Coll., unless otherwise stated. Tabulates, in a complete faunal list of the Nanaimo series of each island, 1 fish, 9 crustaceans, 28 cephalopods, 46 gastropods, 68 pelecypods, 3 brachiopods, and 1 anthozoan. Bibliography.—*F. Anderegg.*

11525. **MATHEWS, ASA A. L. The lower Triassic cephalopod fauna of the Fort Douglas area, Utah.** *Walker Mus. Mem.* 1(1): 1-46. 11 pl., 1 fig. Univ. of Chicago: Chicago, 1929.—Lists 19 cephalopods and describes the following species: *Pseudosageceras intermontanum**, *Cordillerites* **compressus*** (p. 3), *Ophiceras* **matheri*** (p. 4), *Xenodiscus* **hannai*** (p. 5), *X.* **douglasensis*** (p. 5), *Meekoceras* **davisi*** (p. 6), *M.* **hertleini*** (p. 6), *Anasibirites* **kingianus*** (*Sibirites k.* Waagen) (p. 8), *A.* **discoides** (*Sibirites d.* Waagen) (p. 9), *A.* **ceratitoides** (*Sibirites c.* Waagen) (p. 9), *A.* **salisburyi*** (p. 9), *A.* **angulosus** (*Sibirites a.* Waagen) (p. 10), *A.* **madisoni*** (p. 11), *A.* **johannseni*** (p. 12), *A.* **whitei*** (p. 12), *A.* **blackwelderi*** (p. 13), *A.* **fisheri*** (p. 13), *A.* **emmonsi*** (p. 14), *A.* **welleri*** (p. 14), *A.* **powelli*** (p. 15), *A.* **whitfieldi*** (p. 16), *A.* **crickmayi*** (p. 16), *A.* **veranus*** (p. 17), *A.* **ketchumi*** (p. 18), *A.* **perrini*** (p. 18), *A.* **weaveri*** (p. 19), *A.* **wardi*** (p. 19), *A.* **ibex** (*Sibirites i.* Waagen) (p. 20), *A.* **pseudoibex*** (p. 21), *A.* **mcclintocki*** (p. 22), *A.* **bifurcatus*** (p. 22), *A.* **alternatus*** (p. 23), *A.* **romeri*** (p. 23), *A.* **dieneri*** (p. 24), *A.* **clarki*** (p. 25), *A.* **bretzi*** (p. 25), *A.* **vanbuskirki*** (p. 26), *A.* **rollini*** (p. 27), *A.* **edsoni*** (p. 27), *A.* **bassleri*** (p. 28), *A.* **guyi*** (p. 28), *A.* **gibsoni*** (p. 29), *A.* **hyatti*** (p. 30), *A.* **mojsisovicsi*** (p. 30), *Goniodiscus typus**, *G.* **americanus*** (p. 32), *G.* **walcotti*** (p. 32), *G.* **utahensis*** (p. 33), *G.* **shumardi*** (p. 33), *G.* **slocomi*** (p. 34), *G.* **ornatus*** (p. 34), *G.* **butleri*** (p. 35), *G.* (?) **varians*** (p. 35), *Kashmirites subarmatus**, *K.* **wasatchensis*** (p. 37), *K.* **thornei*** (p. 38), *K.* **gilberti*** (p. 38), *K.* **resseri*** (p. 38), *Keyserlingites* **seerleyi*** (p. 39), **WASATCHITES** (p. 40), type *W.* **perrini*** (p. 40), *W.* **meeki*** (p. 41), *W.* **magnus*** (p. 41), *W.* **quadratus*** (p. 42), **GURLEYITES** (p. 42), to include *G.* **smithi*** (p. 43), *G.* **bastini*** (p. 44), *G.* **chamberlini*** (p. 44), *G.* **milleri*** (p. 45), and *G.* **boutwelli*** (p. 45).—*F. All of above, except as noted, are from the State of Parahyba do Norte. Cephalopoda: *Eutrephoceras* **pernambucense** (*Nautilus sowerbyanus* White not d'Orbigny) (p. 249), Lr. Eocene, State of Pernambuco; *Actaeonella* **lucianoi*** (p. 257), *A.* **pompei*** (p. 259), *A.* **tamandarensis*** (p. 261), *Lima* (*Plagiostoma*) **fazendaestivica*** (p. 265), all Up. Turonian to Emscherian, State of Pernambuco; *Elobiceras bahiaense**, Up. Albion of Lr. Cretaceous, Bahia. The cephalopods of the State of Sergipe are discussed; *Puzosia* **garajauana** (*Ammonites hopkinsi* (?) White not Forbes) (p. 289). The relations of *Lopatina, Pseudocucullaea* and *Eusebia* are discussed.

11527. **MISCH, PETER. Pseudorthoceras knoxense Girty im Karnischen Oberkarbon.** *Mitteil. Naturwiss. Ver. Steiermark* 67: 121-122. 1 fig. 1930.—First time reported from Europe.

11528. **MOORE, E. W. J. Species of the genus Dimorphoceras in the Bowland shales.** *Geol. Mag.* 67(790): 162-168. 2 fig. 1930.—The genotype and several other species and varieties of *Dimorphoceras* are described: *D. gilbertsoni** (Phillips) and an unnamed variety*; *D. discrepans** Brown; *D. looneyi** (Phillips); *D.* spp. *a** and *b**; *D.* aff. *denticulatum** (Schmidt); *Neodimorphoceras* **hawkinsi*** (p. 168). Types in Brit. Mus.—*M. A. Fenton.*

11529. **NICHOLLS, A. G. On the breeding and growth-**

rate of the black-lip pearl oyster (Pinctada margaritifera). *Rept. Great Barrier Reef Committee* 3: 26-31. 2 pl. 1931.—On Low Isles, Queensland, spawning occurs in November and May, at 25-28.4° C. Young specimens nearly double their width and length in a year. Notes on habits and habitat are given.

11530. ÖKLAND, FRIDTHJOF. Bemerkungen zu S. Jaeckel's Mitteilung "Zur Molluskenfauna Norwegens." *Arch. Molluskenk.* 63(2): 70-72. 1931.—Several criticisms are made.—*H. B. Baker.*

11531. OOSTINGH, C. H. Mollusca from Sibolga (Tapanoeli). *Misc. Zool. Sumatrana* 53. p. 1-4. 1931.—A list of 54 spp. of marine and submarine mollusks.

11532. ORTON, J. H. Transplantation of Portuguese oysters into South African waters. *Nature* [*London*] 127(3204): 485-486. 1931.—Transplantation of *Ostrea angulata* to So. Africa would probably be highly beneficial. The south-east coast of Natal has conditions of climate, etc., such that transplantation would probably be successful.

11533. PEILE, A. J. Sinistrality in Bacillum. *Proc. Malac. Soc. London* 19(4): 187. 1931.—*B. cassiacum.*—*H. B. Baker.*

11534. PETRBOK, JAR. Zebrinus detritus Müll. in Böhmen. *Arch. Molluskenk.* 63(2): 86-92. 1931.—Northern specimens are usually dwarfed.—*H. B. Baker.*

11535. PETRBOK, JÁR. Bedeutung der Mollusken für die prähistorische Archäologie. *Arch. Molluskenk.* 63(3): 131-132. 1931. Land snails in graves of ancient Thuringians (Czechoslovakia) indicate the use of plants for burial decorations.—*H. B. Baker.*

11536. PFEIFFER, KARL L. Die Murellen Westsiziliens. *Arch. Molluskenk.* 63(3): 93-116. 3 pl. 1931.—The relationships of the species are discussed, with descriptive notes, tables of dimensions and figures of most of them. [*Helix*] *globularis* ssp. transiens* (p. 103) and [*H.*] *platychela* ssp. excelsa* (p. 105).—*H. B. Baker.*

11537. SCHILDER, F. A. Zwei neue Trivia (Cypraeacea: Eratoidae). *Arch. Molluskenk.* 63(1): 42-44. 1 pl. 1931.—*Trivia* (*Niveria*) hybrida* (p. 42) and *T.* (*Pusula*) *sanguinea* ssp. circumdata* (p. 43) are described without locality.—*H. B. Baker.*

11538. SCHREITMÜLLER, WILHELM. Die Donauschwimmschnecke und die Fluss-schwimmschnecke. *Das Aquarium* 1931(Jan.): 13-15. 4 fig. 1931.—Popular description of *Neritina danubialis**, *N. fluviatilis**, and *N. transversalis**.

11539. STRECKER, JOHN K. The distribution of the Naiades or pearly fresh-water mussels of Texas. *Baylor Univ. Mus., Spec. Bull.* 2. 1-71. 1931.—The Texas fauna of Naiades includes 59 spp. and varieties, based on collections in 81 counties. Records and synonymy are given for each species, and then lists are presented for each river and drainage system.

11540. TAKI, ISAO, and IWAO TAKI. Studies on Japanese chitons (5). [In English, with Japanese summary.] *The Venus* [*Japan*] 2(4): 178-185. 8 fig. 1931.—*Ischnochiton* (*Stenoplax*) venustus* (p. 178), Japan, type in authors' coll. A list of the 9 known spp. of the section *Stenoplax*, with synonymies, is appended.

11541. TETENS, ARNOLD. Sammelgeräte für den Konchyliologen. *Arch. Molluskenk.* 63(3): 123-128. 1 pl. 1931.—A dredge and hand-rakes, with and without bags, are described for the collection of bivalves.—*H. B. Baker.*

11542. TOMLIN, J. R. le B. Reports on the marine Mollusca in the collections of the South African Museum. V. The Scaphopoda. *Ann. South African Mus.* 29(2): 337-340. 1 fig. 1931.—*Dentalium* subterlineatum (p. 337), Cape Point; *D. strigatum* Gould (=*D. belcheri* Sowerby); *D.* (*Fissidentalium*) salpinx (p. 338), near Cape Point; *D.* (*F.*) platypleurum (p. 339), off Natal coast; *D.* (*Compressidens*) capense (p. 340), off Cape Point. Types in S. African Mus.

11543. VERCO, JOSEPH C., and BERNARD C. COTTON. The spermatophore of Sepioteuthis australis (Quoy & Gaimard). *Proc. Malac. Soc. London* 19(4): 168-170. 2 pl., 1 fig. 1931.—The mechanics of its rupture are discussed.—*H. B. Baker.*

11544. WENZ, W. Süsswassermollusken aus den Mediterranablagerungen des Mecsekgebirges (Südwestungarn). *Arch. Molluskenk.* 63(3): 116-122. 1 pl. 1931.—*Congeria* böckhi* (p. 117) and *Bulimus* vadászi* (p. 118), with sspp. vadászi* (p. 118) and tylopomoides* (p. 120) from the Helvetian.—*H. B. Baker.*

11545. WEYL, RICHARD. Über einen grossen Findling von Holsteiner Gestein, gefunden am Kaiser-Wilhelm-Kanal bei Kiel. *Zeitschr. Geschiebeforsch.* 7(1): 7-15. 2 fig. 1931.—This block of sandstone, excavated from the Kaiser-Wilhelm Canal at Kiel, contains a rich molluscan fauna (38 spp. are listed), which indicates the Up. Miocene age of the country rock, hitherto known only from small fragments.

11546. WINCKWORTH, R. Mollusca from Pulicat Lake. *Proc. Malac. Soc. London* 19(4): 188-189. 1 fig. 1931.—The fauna of this brackish water lagoon near Madras, India, is discussed.—*H. B. Baker.*

11547. ZIMMERMANN, KLAUS. Zur Kenntnis von Agriolimax reticulatus (Müll.) und A. agrestis (L.). *Arch. Molluskenk.* 63(1): 51-52. 1931.—Notes on ecology and distribution are given.—*H. B. Baker.*

11548. ZIMMERMANN, STEPHAN. Orcula fuchsi n. sp. *Arch. Molluskenk.* 63(1): 44-46. ½ pl. 1931.—*O.* fuchsi*, Austria.—*H. B. Baker.*

11549. ANONYMOUS. Literatures of Japanese conchology (1930-1931). *The Venus* [*Japan*] 2(4): 201-208. 1931.—One hundred and sixty-three titles, largely in Japanese.

MYRIOPODA AND ONYCHOPHORA

R. V. CHAMBERLIN, *Editor*

(See also in this issue Entry 10925)

11550. BROLEMANN, H. W. Myriapodes recueillis par M. le Dr. H. Gauthier en Algérie. *Bull. Soc. Hist. Nat. Afrique du Nord* 22(4): 121-134. 17 fig. 1931.—A record of 11 Diplopoda and 16 Chilopoda. Diplopoda: *Archiulus* Berlese (=*Schizophyllum* Verh.); *A.* aumalensis (*Schizophyllum fusco-unilineatum aumalense* Brol.) (p. 121); *A.* albosignatus (p. 123); *A.* gauthieri* (p. 123); *Cylindroiulus* (*Phalloiulus*) distinctus* (*Iulus d.* Lucas) (p. 125); *C. d.* ssp. gauthieri* (p. 127).

11551. LAWRENCE, R. F. A new peripatopsid from the Table Mountain caves. *Ann. S. African Mus.* 30(1): 101-107. 3 fig. 1931.—*Peripatopsis*, key to 8 spp.; *P.* alba* (p. 103), a blind cavernicolous sp., Cape Province.

11552. LOHMANDER, HANS. Caspiopetalum, eine neue Diplopoden-Gattung aus dem russischen Zentralasien. *Arkiv. Zool.* [*Stockholm*] 22B(2, No. 1): 1-6. 1 pl. 1931.—CASPIOPETALIDAE n. fam. (p. 5) [suborder Lysiopetaloidea], erected for CASPIOPETALUM (p. 1), type *C.* schestoperovi* (p. 5), S. W. Turkestan; *C.* serratum* and *C.* nodifrons* (p. 5), Bokhara.

11553. RÉMY, PAUL. Un nouveau type de Pauropode: Decapauropus cuenoti, nov. gen., nov. spec. *Arch. Zool. Exp. et Gén., Notes et Rev.* 71(2): 67-83. 1931.—DECAPAUROPUS (p. 67), near *Allopauropus*, type *D.* cuenoti ♀* (p. 67), France. The adult* has 10 pairs of ambulatory legs, and certain intermediate stages* have 9 pairs, as in *Allopauropus sequanus**. The Pauropodidae are redefined.

CRUSTACEA

MARY J. RATHBUN, *Editor*
WALDO L. SCHMITT, *Associate Editor*
CHANCEY JUDAY, C. DWIGHT MARSH, H. A. PILSBRY, CLARENCE R. SHOEMAKER, CHARLES B. WILSON, *Assistant Editors*

(See also in this issue Entries 9181, 10072, 10633, 11243, 11246, 11247, 11251, 11255, 11259, 11439, 11444, 11464, 11524, 11526)

11554. ABRAHÁM, AMBROSIUS, und ALEXANDER WOLSKY. Über die Nerven und Nervenendigungen der Antennen einiger Landisopoden. *Zool. Anz.* 84(11/12): 316-323. 4 fig. 1929.

11555. ANDREWS, E. A. Spermatophores of an Oregon crayfish. *Amer. Naturalist* 65(698): 277-280. 1931.—A detailed account of the diffuse distribution of the spermatophores of the crayfish *Potamobius trowbridgei*, in which a greater number of sperms are transferred than in the genus *Cambarus*, which uses a special receptacle. It is inferred that natural selection might have aided in formation of the more specialized and parsimonious method of sperm transfer of *Cambarus* from the more primitive and wasteful methods such as found in *Potamobius*.—*E. A. Andrews.*

11557. BENNETT, E. W. Notes on New Zealand Brachyura and related crustaceans. *Rec. Canterbury Mus.* 3(4): 255-261. 4 fig. 1930.—New Zealand *Petrolisthes elongatus* inhabiting smooth, water-worn stones of intertidal zone resembles such stones in color and texture; *Paralomis hirta* of Australia is equally well concealed among rough, coarse-grained granites, each sp. reflecting a prominent difference in the coastal rocks of the 2 countries; both spp. are abundant in intertidal zones. The conspicuous reddish *Petrochele spinosus* of the same zone is rare. *Petrolisthes novae-hollandae* is admitted to the fauna of N. Zealand. *Porcellana rupicola* is placed in a hypothetical list. The type of *Stenorhynchus fissifrons* Haswell is located in the Australian Mus., Sydney. *Portunus* borradailei* (p. 246), "New Zealand," type (small ♂) in Macleay coll., Sydney Univ. The author postulates that *Marestia mawsoni* Rathbun = megalopa of *Plagusia chabrus* L. A paper by W. Maxwell Young (1929) on crabs of Chatham Isls., is reviewed. Bennett announces his work monographing the Hymenosomidae and solicits loan of specimens. He discusses an "alleged southern element" in N. Zealand fauna, and concludes that "evidence from Brachyura is negative, except that *Halicarcinus planatus* demonstrates the possibility of dispersal of marine organisms throughout the Antarctic under present geographical and climatic conditions." A bibliography of 10 titles is given.—*A. H. Norton.*

11558. BERE, RUBY. Copepods parasitic on fish of the Trout Lake region, with descriptions of two new species. *Trans. Wisconsin Acad. Sci. Arts and Lett.* 26: 427-436. 2 pl. 1931.—Data are presented on the number of Wisconsin fishes examined, the number parasitized, and the chemical conditions of the lakes from which the fish were taken. *Argulus* biramosus ♀* (p. 428), on body of yellow perch; *Ergasilus* confusus ♀* (p. 431), ♀* on yellow perch, wall-eyed pike, rock bass, small-mouthed black bass, lake trout, cisco, and white fish. Types in U. S. Nat. Mus. *Achtheres coregoni* was taken on the cisco and *A. micropteri* on black bass.

11559. BERG, KAJ. A faunistic and biological study of Danish Cladocera. *Vidensk. Medd. Dansk Naturhist. Foren.* 88: 31-112. 3 pl. (1929) 1930.—Sixty-three species (none new to science, 8 new to Denmark) are listed, together with ecological notes, distribution, types of habitats, and reproduction. A brief review of Danish literature on Cladocera is given. The species new to Denmark are: *Daphnia atkinsoni* Baird, *Iliocryptus agilis* Kurz, *Streblocerus serricaudatus* (S. Fischer), *Alonopsis ambigua* Lilljeborg, *Kurzia latissima* (Kurz), *Alonella excisa* (Fischer), *Chydorus gibbus* Lilljeborg, *Anchistropus emarginatus* G. O. Sars.—*F. A. Stromsten.*

11560. BIGELOW, ROBERT PAYNE. Stomatopoda of the southern and eastern Pacific Ocean and the Hawaiian Islands. *Bull. Mus. Comp. Zool. Harvard Coll.* 72(4): 105-191. 2 pl., 9 fig. 1931.—Descriptive and distributional studies in 85 spp. of *Gonodactylus*, 2 of *Odontodactylus*, 3 of *Pseudosquilla*, 1 of *Lysiosquilla*, and 3 of *Squilla* J. C. Fabricius (*Chloridella* Miers). The latter name is treated in its long established sense, and not in the sense of Gronov (1760) or Müller (1776), and a ruling has been requested to suspend the rules and establish this usage. *Squilla* mauiana* (p. 177), Hawaii, type in U. S. Nat. Mus. Several spp. are illustrated. The report is based on collections made by D. S. Jordan in Samoa for the U. S. Fish Commission in 1902; by the steamer "Albatross" in Hawaiian Isls. and vicinity in the same year; and by the Agassiz Expedition of the "Albatross," 1904-1905 (1 specimen only). One specimen of *Squilla polita* from Monterey Bay, not a part of the preceding expeditions, establishes a northern record for the species.

11561. BOONE, [PEARL] LEE. Notes on the West Indian crabs of the genus Actaea. *Bull. Amer. Mus. Nat. Hist.* 61(3): 117-127. 8 fig. 1930.—The author considers *Actaea bifrons* a synonym of *A. setigera* and also does not admit the validity of *A. rufopunctata nodosa* as a subspecies. *A. acantha** H. Milne Edwards, *A. setigera** H. Milne Edwards, *A. palmeri** Rathbun, and *A. rufopunctata nodosa** Stimpson are described and their known distribution given.—*M. W. Smith.*

11562. BOONE, [PEARL] LEE. Scientific results of the cruises of the yachts "Eagle" and "Ara," 1921-1928, William K. Vanderbilt, commanding. Crustacea: Anomura, Macrura, Schizopoda, Isopoda, Amphipoda, Mysidacea, Cirripedia, and Copepoda. *Bull. Vanderbilt Marine Mus.* 3: 1-221. 83 pl., 5 fig. 1930.—Ninety-two species from 4 different areas, W. Indies, Labrador-New England, tropical American Pacific, and Mediterranean. Each species is described at length and most are figured. *Porcellana* rosamondae* (p. 79), Panama; *Alpheus* vanderbilti* (p. 163), Florida.—*M. J. Rathbun.*

11563. BRIAN, ALESSANDRO. Copepodi dei laghi albanesi di Ochrida e di Malik. [Copepods of the Albanian lakes Ochrida and Malik.] *Atti Accad. Sci. Veneto-Trentino-Istriana* 21: 47-50. 1930.—A list of 6 spp. taken in the plankton.

11564. BRIAN, ALEXANDRE. Description d'une nouvelle espèce de Caligus (Copépode parasite) de la Méditerranée. *Bull. Soc. Hist. Nat. Afrique du Nord* 22(4): 119-120. 1 pl. 1931.—*Caligus* argilasi* (p. 119), on *Mugil auratus*, Algeria. Illustrations are given of the furcula sternalis of other spp. of *Caligus*.

11565. CAROLI, E. La fase "microniscus" di "Ione thoracica" (Montagu), ottenuta per allevamento sui Copepodi. [Microniscus stage of I. thoracica obtained by raising on copepods.] *Atti R. Accad. Naz. Lincei Rend. Cl. Sci. Fis. Mat. e Nat.* 8(7/8): 321-327. 1928.—For the first time the development of an epicaridian larva is followed from emergence from the marsupium until it is in the act of attachment to the final host. As soon as they emerge, the larvae of *I. thoracica* attach themselves to calanoid copepods, usually the ♀♀ of *Acartia* (*clausi* or *verrucosa*). After about 3 days they begin to enter the microniscus stage. The author calls the intermediate stage "praemicroniscus." There are 4 microniscus stages, the last of which shows resemblances to the succeeding cryptoniscium stage. This last stage is free swimming and goes in quest of the final host. The

micronisicus is held to be nonparasitic and to use the calanoids only as a means of dispersal.—*G. Colosi (transl. by H. L. and C. H. Blake)*.

11566. **DANTAN, J.-L.** Recherches sur le Nereicola ovata Keferstein. *Ann. Inst. Océanograph.* 7(4): 175-197. 20 fig. 1929.—*N. ovata* was found parasitic on *Platynereis dumerilii* and *Nereis rava* from the Bay of Algiers. A complete redescription, with figures, is given of the external morphology and appendages. The internal anatomy is also described. The effects of the parasite on the host are noted. In *P. dumerilii* the parapodia of parasitized individuals of both sexes are reduced and, in the ♂, the lobes of the pygidial rosette are reduced or disappear. In *N. rava*, the parasitized ♂ is little affected save by a slight reduction in the parapodia, the pygidial rosette being quite unaffected. In the ♀, on the other hand, the parapodia are profoundly affected and reduced. The author discusses these effects and their causes.—*W. M. Tattersall.*

11567. **GAUTHIER, HENRI.** Mission saharienne Augiéras-Draper, 1927-1928. Cladocères, Ostracodes, Phyllopodes anostracés et conchostracés. *Bull. Mus. Nat. Hist. Nat. [Paris]* 2(1): 92-116. 12 fig. 1930.—Species collected are enumerated, and a systematic study made of the following spp.: *Camptocercus rectirostris** Schödler; *Eurycercus lamellatus** (Daday); *Acocypris capillata** Vávra; *Cyprinotus incongruens** (Ramdohr). *Macrothrix capensis* v. **monodi** (p. 95); *Stenocypris* **monodi*** (p. 101); *Leptestheria cortieri* Daday unnamed var. figured but not described.—*H. Gauthier (transl.)*.

11568. **GAUTHIER, HENRI.** Phyllopodes et Cladocères de la collection de l'Institut scientifique chérifien. *Bull. Soc. Sci. Nat. Maroc* 9(1/6): 72-76. 1 pl., 1 fig. 1929.—Enumeration of the spp. examined. Description of an aberrant form of *Daphnia magna** Straus.—*H. Gauthier (transl.)*.

11569. **HEROLD, WERNER.** Beiträge zur Kenntnis der Trichonisciden. I. Die Untergattung Spiloniscus Racovitza in Deutschland und im Ostbaltikum. *Zool. Jahrb., Abt. Syst. Ökol. u. Geogr. Tiere* 57(3/4): 215-252. 10 fig. 1929.—The author summarizes his findings as follows: (1) The exopodites of the 1st pleopods of the ♂ of the German and east Baltic representatives of the subg. *Spiloniscus* furnish the only reliable specific characters; (2) the form of the endopodite of the 1st pleopod of the ♂ is more constant, showing characters of specific value, though the relationships of certain species of *Spiloniscus* may be traced through it, as in the *muscivagus* group in the southeast; (3) of the 2 related species, *Trichoniscus rhenanus* Graeve and *T. elisabethae** Herold, the first is the western form, the second the eastern; (4) *T. pygmaeus* v. *horticola* Graeve represents a species distinct from *pygmaeus* and must be designated as *T.* **horticolus*** (Graeve) (p. 234); as a result *T. pygmaeus** has not yet been recorded from Germany; (5) *T. batavus** likewise is not to be recorded as German, the determination of a mid-German *Trichoniscus* ♂ as this species not being substantiated; (6) *T. verhoeffi** Dahl is not only insufficiently described but is unrecognizable as well; (7) heretofore all north German and east Baltic and also, apparently, the Swedish ♂♂ of *Spiloniscus* have been found at ecologically optimal localities, thus making it appear that the development of purely parthenogenetic races ("caelek-races") are determined by conditions unfavorable for normal reproduction; (8) the number of offspring of like sized *Spiloniscus* ♀♀ seasonally augments toward spring, and especially in a northern and an eastern direction; (9) the German ♀♀ become sexually mature earlier than those from east Baltic; (10) in July the total number of offspring of equal numbers of ♀♀ of all sizes increases in a northern and an eastern direction; (11) the reproductive period in north Germany lasts from about the beginning of April to the middle of October, in the east Baltic it appears to be about 1½ months shorter. The author particularly deals with 10 spp. of *Trichoniscus*, in most cases figuring the particular characters discussed in detail.—*W. L. Schmitt.*

11570. **KLIE, WALTER.** Zwei neue Arten der Ostracoden-Gattung Candona aus unterirdischen Gewässern im südöstlichen Europa. *Zool. Anz.* 96(7/8): 161-168. 12 fig. 1931.—*Candona* **puteana*** (p. 161), Jugoslavia; *C.* **trigonella*** ♀ (p. 165), Austria.

11571. **MONOD, TH.** Über einige indo-pazifische Decapoden der Meeresfauna Syriens. *Zool. Anz.* 92(5/6): 135-141. Map, 7 fig. 1930.—The following Indo-Pacific Decapoda from the coast of Syria and Palestine are added to the Mediterranean fauna: *Penaeus semisulcatus**, *P. japonicus**, *Penacopsis monoceros**, *P. stebbingi**, *Neptunus pelagicus**, *Charybdis (Goniosoma) merguiensis**, and *Myra fugax**.—*M. J. Rathbun.*

11572. **MONTE, OSCAR.** Os tatusinhos. [Armadillidium and other Isopoda.] *Bol. Agric. Zootech. e Vet. [Minas Geraes]* 4(1/3): 63-64. 1 fig. 1931.—Description and control.

11573. **PARENZAN, PIETRO.** Nota sui Cladoceri dei grandi laghi dell'Albania orientale. [The Cladocera of the great lakes of eastern Albania.] *Atti Accad. Sci. Veneto-Trentino-Istriana* 21: 75-80. 1930.—A list of 14 spp., with notes.

11574. **PARENZAN, PIETRO.** Cladocerofauna autunnale ed invernale di alcuni laghi dell'Alto Adige. [Fall and winter Cladocera of some lakes of the high Adige.] *Atti Accad. Sci. Veneto-Trentino-Istriana* 21: 81-107. 1930.—An ecological study of 18 spp. in 6 families, arranged according to lakes, altitudes, and seasonal occurrence.

11575. **PEARSE, A. S.** Parasites of Fukien crabs. *Proc. Nat. Hist. Soc. Fukien Christian Univ.* 3: 10-16. 2 pl. 1930.—Foods and parasites of crabs at the mouth of the Min River are described. Land crabs have more parasites than aquatic spp. Four new parasites are described: A trematode, **PARAGONO** (p. 11) (Troglotrematidae), type *P.* **kelloggi*** (p. 11); two isopods, *Leidya* **ucae***, *L.* **sesarmae*** (p. 13), and a mite, *Tyroglyphus* **eriocheir*** (p. 14).—*A. S. Pearse.*

11576. **REED, F. R. COWPER.** A review of the Asaphidae. Part I. *Ann. and Mag. Nat. Hist.* 5(27): 288-320. 1930.—Of the 66 genera of trilobites ascribed by various authors to the Asaphidae, 28 may still be allowed without serious doubt, 3 with some question; 18 genera may be ascribed to the subfam. Ogygiocarinae, viz., *Asaphellus, Barrandia, Bellefontia, Hemigyraspis, Homalopteon, Homoglossa, Megalaspis, Nileoides, Niobe* (partim), *Ogyginus, Ogygiocaris, Ogygopsis*, ? *Platypeltis, Ptychocheilus, Rhinaspis, Symphysurina*, ? *Vogdesia, Xenostegium*. 14 genera may be ascribed to the subfamily Asaphinae, viz., *Asaphus, Basilicus, Brachyaspis, Ectenaspis*, ? *Gerasaphes, Homotelus, Isoteloides, Isotelus, Megalaspides, Niobe* (partim), *Ogygites, Onchometopus, Pseudasaphus, Ptychopyge*. The genera *Asaphelina, Symphysurus, Illaenurus, Nileus, Hyboaspis*, and others often referred to the Asaphidae should be removed.—*J. H. Bradley, Jr.*

11577. **SHEN, CHIA-JUI.** The crabs of Hong Kong. Part II. *Hong Kong Naturalist* 2(3): 185-197. 3 pl., 12 fig. 1931.—Descriptive studies of *Philyra tuberculosa**, *Leucosia rhomboidalis**, *Lyreidus integra**, *Phalangipus longipes**, *Halimus dicanthus**, and *Sesarma sinensis**.

11578. **SHOEMAKER, CLARENCE R.** The stegocephalid and ampeliscid amphipod crustaceans of Newfoundland, Nova Scotia, and New Brunswick in the United States National Museum. *Proc. U. S. Nation. Mus.* 79(22): 1-18. 6 fig. 1931.—A report of 4 spp. of Stegocephalidae and 12 of Ampeliscidae. Stegocephalidae: *Phippsiella similis*, first record for Western Hemisphere; *P. minima** and *Andaniella pectinata**, descriptive notes, first records for eastern coast of N. Amer. Ampeliscidae: *Ampelisca aequicornis, A. latipes, A. amblyops, A. gibba*, and *Haploops similis*, first records from eastern coast of N. Amer.; ? *Ampelisca typica*, new to Western Hemisphere; *Haploops* **spinosa*** (p. 13), type in U. S. Nat. Mus.

11579. **SMEDLEY, N.** A fresh-water crab, Paratelphusa sexpunctatum (Lanch.) in the Malay Peninsula. *Bull. Raffles Mus.* 5. [68]-[70]. 1 pl., 2 fig. 1931.—First

description of ♂*. Describes the damage done by these crabs in the rice fields and the methods used to counteract it.

11580. **STEPHENSEN, K., et J.-M. PIRLOT.** Les amphipodes hypérides du genre Mimonectes Bovallius (inclus: Sphaeromimonectes Woltereck et Parascina Stebbing) et de quelques genres voisins (Archaeoscina Stebbing, Micromimonectes Woltereck, Microphasma Woltereck et Proscina n. g.). *Arch. Zool. Exp. et Gén.* 71(4): 501-553. 18 fig. 1931.—Mimonectidae: *Mimonectes* Bovallius (=*Parascina* Stebbing, *Sphaeromimonectes* Woltereck); *Mimonectes loveni* Bov. (=*Sphaeromimonectes cultricornis* Wolt., and probably *Parascina cheirocuri** Pirlot), ♀* with incubatrix plates described in detail; *M. sphaericus* ♀* with marsupial plates described; *M. fowleri* ♀* with ovitectrices described; *M.* **valdiviae** (*Sphaeromimonectes v.** Wolt.) (p. 530); *M.* **gaussi** (*S. g.* Wolt.) (p. 531); *M.* **scinoides** (*S. sc.* Wolt.) (p. 531); *M.* **diomedeae** (*S. d.* Wolt.) (p. 531); *M.* **spandlii*** (p. 532), Atlantic Ocean near Portugal, and Morocco. Archaeoscinidae: *Micromimonectes* **steenstrupii** (*Mimonectes s.* Bovallius) (p. 534), ♀* with ovitectrices described; *Archaeoscina bonnieri* Stebbing is probably the ♂ of *Microm. steenstrupii.* Family uncertain: *Microphasma agassizii**, descriptive notes. Scinidae: **PROSCINA** (p. 543), near *Scina,* based on *Proscina* **stephenseni** ♀* (*Parascina s.* Pirlot) (p. 544) and *P.* **magna** ♂* (p. 545), Atlantic Ocean, the type of the latter in Mus. Océanographique de Monaco. The Hyperiidea Physosomata are divided into 2 new subtribes, the **SCINIFORMATA** (p. 551) for Archaeoscinidae (Pygmaeidae), Mimonectidae, and Scinidae; and the **LANCEOLIFORMATA** (p. 551) for Lanceolidae and Chuneolidae, and provisionally the genera *Mimonecteola* and *Microphasma. Mimonectes* **setosus** (*Parascina setosa* Barnard) (p. 552).

11581. **VERWEY, J. Einiges über die Biologie Ost-Indischer Mangrovekrabben.** *Treubia* 12(2): 167-261. Map. 9 pl., 20 fig. 1930.—A discussion of the ecology and biology of certain mangrove crabs, *Sesarma, Metaplax, Ilyoplax, Uca, Scylla,* and others, together with some observations on mangrove gasteropods. Five ecologic zones are distinguished. These are characterized by particular crabs and gasteropods, and by the degree of moisture of the substratum upon which the animals depend for food. These zones are recognizable at Batavia, and elsewhere among mangroves. The chief biological peculiarities of mangrove animals are resistance to changes of salinity, mud feeding, and the fact that many are amphibious. These alternative "breathers" are of 2 kinds, those which are chiefly "lung breathers" and those which are primarily dependent on gills. With the exception of *Thalassina anomala* and *Macrophthalmus definitus,* the various mangrove animals stick closely to their particular zones and all construct burrows which descend to ground water in order to supply the moisture required. *Thalassina* is independent of zonal restrictions as it finds its nourishment beneath the surface. Ecologic, biologic, and physiologic observations upon *Uca signata* are given in considerable detail and compared with those made in other species. The remarkable "waving" of the claws of *Uca* and other crabs is not amatory, but serves as a warning gesture to keep intruders from each particular crab's feeding range. These movements appear to occur in species which live under much crowded conditions, and which are individually bound to a particular burrow, and find their food in its immediate vicinity. The extent of the home area, feeding range, and fighting are discussed. The food and feeding habits are considered and the mouth parts are figured and compared with those of *Cancer* and *Carcinus.* The significance of their divergence from those of *Uca* is not clear. The gastric secretions of *Uca* in an alkaline medium digest fibrin, digest connective tissue (catgut) slowly, and contain a lipase, amylase, and invertase. According to their mode of breathing, mangrove crabs are of 2 kinds: Those which, when removed from the water, "pump" the water out of the branchial chamber, and then draw it in again after it has spread out over the surface of the body; and those which "pump" air through the water. Of the species studied, *Sesarma, Ilyoplax, Metaplax,* and *Macrophthalmus* belong to the first group, and *Grapsus, Uca, Ocypode,* and *Potamon* to the second. That *Ocypode* lives but a short time under water is incorrect. *Uca* quickly dries out if there is no water available for moistening. Moisture, a branchial chamber that in part functions as lung, and firm gill plates that do not readily stick to one another enable the Ocypodes to endure the hot tropical sun. At flood tide *Sesarma taeniolata* climbs trees, while *S. bataviana* seeks its burrow. Old *S. taeniolata* lives longer in the air than old *bataviana,* though young *taeniolata,* of the size of old *bataviana* dries out just as quickly as the latter. Only because of their size do old *taeniolata* survive so long in the air. There are no differences in the structure of the branchial chamber or the gills in these 2 species. Non-pumping species dry out sooner than the pumping species. Apparently the mere passing of air through the water filled branchial chamber results in a greater loss of water than when it is pumped out and drawn in again. That many tropical animals live very close to the maximal temp. which they can endure also holds good for *Uca. Uca* is an unquestioned diurnal animal; the degree to which light and temp. are of effect here was not investigated. Seeing with *Uca* is chiefly perception of movement, to a lesser degree the perception of form. *Uca* seems to reproduce throughout the year. *Sesarma taeniolata,* and less markedly *S. bataviana,* show a periodicity in their reproductive cycle. The length of time in which the eggs complete their development may be of quite variable duration. The larvae of *Paracleistostoma* differ morphologically from those of *Sesarma* and *Uca,* for one thing, lacking the dorsal spine. The author also makes certain observations upon the growth and coloration of *Uca.*—*W. L. Schmitt.*

11582. COCKAYNE, E. A., et al. Abstract of proceedings. *Proc. South London Ent. and Nat. Hist. Soc.* 1931-2 pp. 30-84. [1931].—In the meeting of April 24, 1930, E. A. Cockayne (p. 37-38) stated that [Lepidoptera] *Taeniostola, Chortodes, Petilampa,* and *Miana* have similar larvae, and should be placed near each other and not separated, as now, by genera with different larval types. In *Apamea, A. secalis* and *A. ophiogramma* seem to belong to the above group, while the larvae of the other species are very different. H. J. TURNER (p. 38, 39) commented on the genera *Miana* and *Oligia.* In the meeting of Aug. 14, 1930, specimens of Lepidoptera communicated by SNEYD TAYLOR (p. 54) from the Transvaal were exhibited, including *Nudaurelia zambesiana* ssp. *ringleri* [Saturnidae] bred on plum, and *Calamistis fusca* bred from stems of maize. Miss D. G. STEP (p. 54) sent in a specimen of *Bombylius minor* [Diptera] bred from the cell of a *Colletes daviesana* [Apoidea] in England. In the meeting of Sept. 11, 1930, T. H. L. GROSVENOR exhibited results of crossing *Zygaena filipendulae* ♂ with *Z. f. stoechadis* ♀. Meeting of Oct. 9, 1930: E. A. Cockayne contributed "Notes on the larva of *Macrogaster* (*Phragmataecia*) *arundinis,* Hb." Meeting of Oct. 23, 1930: D. L. PALMER exhibited a melanic ♂* form of *Argynnis cydippe* (*adippe*) [sic].

11583. CORSET, JEAN. Les coaptations chez les insectes. *Bull. Biol. France et Belgique, Suppl. 13.* 1-337. 2 pl., 182 fig. 1931.—The volume deals descriptively with the various types of coaptation, or reciprocal adjustment of parts to each other, in the orders of insects. Many of the illustrations are of cross sections showing the nature of the adaptations, which occur on all parts of the body. The work is divided into four parts, anatomical, physiological, biological, and philosophical. The anatomical studies are based upon representatives of the various families in each order, and include 25 Orthoptera, 10 Hemiptera, 137 Coleoptera, 4 Hymenoptera, 10 Lepidoptera, and 2 Neuroptera. Three types of coaptation are distinguished: by juxtaposition, by serration, and by union (as where one part fits into a groove or depression of another). Some of the purposes of coaptation are to assure immobility of certain parts; to synchronize movements in flight; to insure close fitting of parts when in repose. The bibliography contains 105 references.

11584. CRAMPTON, G. C. A criticism of the current theories concerning the origin of metamorphosis in insects, with suggestions for a theory based on mutations. *Entomologist* [*London*] 64(818): 154-158; (819): 171-174. 1931.—The writer brings forth arguments to disprove the contention that the larva of a holometabolous insect is merely a free-living embryo, and shows that they are strictly post-embryonic. He contends that holometabolism is a result of mutations.

11585. GUNN, DONALD L. The function of the air sacs of insects. *Nature* [*London*] 127(3193): 58-59. 1931.—The common view that the air-sacs of those insects which have powers of sustained flight function by buoying up the insect, is incorrect. It is shown, by Archimedes' principle, that the weight of the air displaced by these sacs is too small to be significant. However, the sacs may serve as pumps, increasing tracheal ventilation.

11586. ILLINGWORTH, J. F. Insects in the Waiahole ditch. *Proc. Hawaiian Ent. Soc.* 7(3): 408-409. 1931.—Reports on 11 spp. of insects found floating in the canal, *Adoretus sinicus* and *Charadromyia torrenticola* being present in large numbers.

11587. KAUDELKA, JOSEF. Ein empfehlenswerter Klopfschirm. *Internat. Ent. Zeitschr.* 25(6): 61-62. 1931.—Description of a beating umbrella.

11588. LUTZ, FRANK E., and W. R. HICKS. An analysis by movietone of a cricket's chirp (Gryllus assimilis). *Amer. Mus. Novitates* 420. 14p. 5 fig. 1930.—Each sound-wave is represented on the movietone film by a line. Knowing the speed at which the film moved, the pitches of the notes were determined. Each "chirp" of *Gryllus assimilis* consists normally of 3 "pulses" of sound so close together as to be indistinguishable by ear. Each pulse starts at a fairly high pitch, rises a bit and then falls to below the starting pitch. The data indicate that each sound-wave is the result of scraping an individual tooth of the "file" and not of a continuous vibration of the wings. Doubt concerning the adaptiveness of the "drum" is suggested.—*F. E. Lutz.*

11601. GARNETT, HENRY. Occurrence of the water mite, Hydrachna geographica Mull., in Lancashire. *North Western Naturalist* 6(3): 162. 1931.

11602. HODGKISS, H. E. The Eriophyidae of New York: II. The maple mites. *New York State* [*Geneva*] *Agric. Exp. Sta. Tech. Bull.* 163. 1-45. 14 pl. 1 fig. 1930.—This part treats especially of species which subsist on foliage of maple trees, the first contribution dealing with mites attacking apples and pears. The activities of many of the Eriophyidae on maple leaves result in galls or other malformations of the tissues. These outgrowths often assume curious shapes or vivid hues that attract attention to the miscreants which on account of their small size might otherwise remain undetected. In some years owing to an abundance of the galls, the foliage of hard and soft maples, especially, becomes misshapen and large numbers of the leaves drop, lessening the value of the trees for ornamental purposes. Other kinds of maples attacked by mites are the black maple, *Acer negundo* Linnaeus; red maple, *A. rubrum* Linnaeus; Norway maple, *A. platanoides* Linnaeus; and the mountain maple, *A. spicatum* Lambert. An examination of leaves of the striped maple, *A. pennsylvanicum* Linnaeus, from widely separated localities, resulted in a failure to detect Eriophyidae or evidences of their characteristic work on this plant. In these studies, 25 spp. of mites have been recognized. The most important of these from an economic standpoint are the soft maple pouch gall mite, *Phyllocoptes quadripedes* Shimer; and the fusiform gall mite, *P. aceris-crumena* Riley, which occurs on the leaves of the hard maple. Other species have been recognized on this host among which are 2 interesting European mites, *P. gymnaspis* Nal. and *Oxypleurites serratus* Nal. The remaining forms including *Eriophyes* aceris* (p. 19), abundant among erineum galls on the under surfaces of leaves of the silver maple, are new to science. *Phyllocoptes quadripedes* and *P. aceris-crumena* hibernate in crevices or wounds in the limbs or under rough bark on the trunks of the trees. As the buds begin to swell in the early spring, the hibernating forms of these species migrate to young unfolding leaves and puncture the epidermal tissues. Galls form at these points which extend a short distance above the surfaces of the leaves and serve as an abode for the mites in which they feed and reproduce. The eggs of the hard and soft maple mites are minute spherical objects and are deposited along the inner surfaces of the galls. The eggs hatch during the latter part of May or early in June and the young larvae feed within the galls until mature. As the season advances the galls usually become discolored and shrivel and the more seriously deformed leaves drop. Coincident with the drying of the leaf tissues the mites return to their winter quarters. Aside from the papers mentioned it does not appear that any well-defined attempt has been made to identify the species of Eriophyidae which subsist on trees of the Aceraceae in this country. In Europe, more extensive taxonomic studies of this group have resulted in the recognition of a large number of species on maples. These live chiefly on *Acer campestre* L., *A. platanoides* L., *A. pseudoplatanus* L., and *A. obtusatum* W. K., where they either form galls or live a vagabond existence on the surfaces of the leaves. Except as previously noted, none of these forms have been recognized in the material we have examined.—*H. E. Hodgkiss.*

11603. JACOT, ARTHUR PAUL. Oribatid mites of the subfamily Phthiracarinae of the northeastern United States. *Proc. Boston Soc. Nat. Hist.* 39(6): 209-261. 10 pl., 1 fig. 1930.—The author reviews the genera and genotypes in this subfamily. He discusses their synonymy, their phylogenetic arrangement, the identification and reidentification of spp., and structures and terminology. PHTHIRACARINI (p. 214) new tribe, type *Phthiracarus* Perty, including also *Steganacarus* Ewing; EUPHTHIRACARINI (p. 214) new tribe, type *Euphthiracarus* Ewing, including also *Pseudotritia* Willmann, *Oribotritia* Jacot, and *Indotritia* Jacot. The systematic account of 23 forms includes detailed descriptions, distributional and habitat records, and figures. There are diagnoses of all genera. There are keys to spp. of *Phthiracarus* and *Euphthiracarus* and to genera of Euphthiracarini. *Phthiracarus* brevisetae* (p. 225), Connecticut; *P.* boresetosum (p. 228) and *P.* erinaceum (p. 230), Maine; *P. setosellum* bryobium* (p. 232), Connecticut; *P.* compressum* (p. 232), Connecticut (type), Maine, and New York; *P.* sarahae* (p. 234), Maine; *Steganacarus* Ewing is shown to have been erroneously placed by Sellnick in the synonymy of *Hoploderma* Michael; *S.* diaphanum* (p. 236), Connecticut; *S.* thoreaui* (p. 239), Maine; *Pseudotritia ardua* mut. obesum* (p. 245) and *P. a.* var. monoheterodactylum (p. 246), Connecticut; *P.* simplex* (p. 248), Maine (type) and Connecticut; *Euphthiracarus flavum* ssp. pulchrum* (p. 250), Connecticut; *E.* punctulatum* (p. 250), New York, Connecticut (type), and Maine; *Oribotritia* carolinae* (p. 257), N. Carolina; *O.* virginiensis* (p. 257), Virginia. Types in Mus. Comp. Zool.—*A. P. Jacot.*

11604. MARSHALL, RUTH. Preliminary list of the Hydracarina of Wisconsin. I. The red mites. *Trans. Wisconsin Acad. Sci. Arts and Lett.* 26: 311-319. 2 pl. 1931.—*Limnochares aquaticus**, *Eylais desecta**, *Protzia* ovata ♀* (p. 312), first species in the genus for N. Amer.; *Hydrachna crenulata**; *H. rotunda**. *H. canadensis**, *H.* bilunata ♀* (p. 314), British Columbia and Wisconsin; *H. schneideri americana**; *H. magniscutata**; *Pseudosperchon verrucosus**, first record for N. Amer.; *Hydryphantes ruber**; *H. tenuabilis**; *H. multiporus**; *Diplodontus despiciens**.

11605. **OUDEMANS, A. C.** Acarologische Aanteekening LXXXV. [Acarological notes.] *Ent. Berichten [Amsterdam]* 7(154/155): 208-212. 1927.—*Aponomma* kerberti (p. 208).

11606. **RADFORD, CHARLES D.** Observations on the tick, Ornithodorus moubata Murray. *North Western Naturalist* 6(3): 155-158. 1931.—Notes on the feeding and breeding habits.

11607. **SCHULZE, PAUL.** Die Zeckengattung Hyalomma I. (H. aegyptium L., detritum P. Sch., volgense P. Sch. u. Schlottke, H. scupense P. Sch. und H. uralense P. Sch. u. Schlottke.) *Zeitschr. Wiss. Biol. Abt. F. Zeitschr. Parasitenk.* 3(1): 22-48. 44 fig. 1930.—A critical review of the genus *Hyalomma*, which is divided into the subgenera *Hyalomma*, *Hyalommina*, and **HYALOMMASTA** (p. 27), type *Hyalomma* (*Hyalommasta*) *aegyptium** L. (=*H. syriacum* Koch). The anatomical details of each species and variety are described and illustrated, and host records are given. *H. detritum* perstrigatum* (p. 34), Chihli Prov., China, type in Zool. Mus., Berlin; *H. d.* rubrum* P. Schulze and Olenev (p. 38), Kazakstan, on *Sus scrofa*, type in Zool. Mus. Acad. Sci. Leningrad.

11608. **SELLNICK, MAX.** Mexikanische Milben I. *Zool. Anz.* 95(5/8): 179-186. 6 fig. 1931.—Oribatidae: **DAMPFIELLA** (p. 180), near *Otocepheus*, type *D.* procera* (p. 180), **PELOPPIA** (p. 183), near *Ceratoppia*, type *P.* serrata* (p. 184), both from Mexico, from dead stem of *Abies religiosa*.

11609. **SSUJETOW, S.** Zur Kenntnis der Gattung Arrhenurus (Hydracarina). *Zool. Anz.* 94(5/8): 213-218. 6 fig. 1931.—*Arrhenurus* boruzkii* ♀ (p. 214) and *A.* sokolowi* ♂ (p. 216), Russia.

11610. **THOR, SIG.** Norwegische Alycidae I-VII. *Zool. Anz.* 94(9/10): 229-238. 4 fig. 1931.—**EPISTOMALYCUS** (p. 233), near *Alycus*, type *E.* clavipilus* (p. 234), from moss, Denmark; *E.* plumipilus* (p. 237), in moss, Norway.

11611. **THOR, SIG.** Über Nanorchestes Topsent et Trouessart 1890=(Syn.) Monalichus A. Berlese 1904 und über eine bisher unbekannte Endung der Tracheenstigmen. *Zool. Anz.* 95(3/4): 106-110. 3 fig. 1930.—*Nanorchestes* T. & T. (=*Monalichus* A. Berl.); *N. amphibius** redescribed with illustrations of thorax, mouth parts and leg, with special attention to the tracheal stigmata.

11612. **UCHIDA, TOHRU.** Einige fernorientalische Arten der Wassermilben. *Zool. Anz.* 94(5/8): 129-138. 14 fig. 1931.—Hydrachnidae: Measurements and descriptive data are given on all species mentioned. New distributional records are cited below: *Limnesia koenikei** and *L. undulata*, Japan; *L. burensis**, Formosa; *Hydrachna* (*Diplohydrachna*) sp.*, larvae found parasitic on *Ranatra chinensis* in Japan; *H.* (*Schizohydrachna*) *nova** Marshall (=*Monohydrachna tokyoensis* Kishida), nymphs often on *Ranatra* and *Nepa*, Japan; *H.* (*S.*) china* ♂ (p. 136), Canton, China; *H.* (*S.*) fukuoka* ♂ (p. 137), Japan. Types in author's coll. Parasitic Protozoa, *Vorticella nebulifera*, were found on *L. koenikei* and *L. undulata*.

11613. **VIETS, K.** Typus und Subgenera in Hydrachna O. F. Müller. *Zool. Anz.* 93(5/6): 173-185. 6 fig. 1931.—The author reviews in detail the nomenclatural history of various spp. described in this genus. New diagnoses are given of *Hydrachna cruenta** Müller (=*H. binominata* Thor, *H. biscutata* Thor, *H. thoni* Piersig, *H. rossica* Dad.) and *H.* skorikowi* (*H. schneideri skorikowi* Piersig, =*H. valida valida* Koen., *H. v. crassirostris* Koen.). The author follows Latreille in fixing *H. cruenta* as the genotype. The genus is separated into the following subgenera: *Anohydrachna* Thor; **RHABDOHYDRACHNA** (p. 184), type *H. comosa* Koen.; *Diplohydrachna* Thor; and *Hydrachna* Müller.

11614. **VITZTHUM, H.** Eine Notiz über Amblyomma longirostre (C. L. Koch 1844). *Zeitschr. Wiss. Biol. Abt. F, Zeitschr. Parasitenk.* 3(1): 49-51. 2 fig. 1930.—Note on a specimen of *Amblyomma longirostre** from *Coendou prehensilis*, from S. Amer.

11615. **WALTER, C.** Biospeologica. LVI. Campagne spéologique de C. Bolivar et R. Jeannel dans l'Amérique du Nord (1928). 6. Arachnides halacariens. *Arch. Zool. Exp. et Gén.* 71(3): 375-381. 9 fig. 1931.—Descriptive notes on *Soldanellonyx chappuisi* and *S. monardi*, from cave, Indiana; **HAMOHALACARUS** (p. 377), near *Limnohalacarus*, based on *H.* subterraneus ♀* (p. 378), also from cave, Indiana.

11616. **[ZASUKHIN, D. N.]** ЗАСУХИН, Д. Н. Материалы к познанию клещей в связи с очередными задачами изучения их на Юго-Востоке РСФСР. [Data for the study of ticks in connection with their present-day importance in southeastern RSFSR.] Вестник Микробиологии, Эпидемиологии и Паразитологии (*Rev. Microbiol., Épidémiol. et Parasitol.*) 9(2): 250-262. [English summary 287-288.] 1930.—Distribution of ticks in the southeastern part of Russia with name of the host, based on data collected by the author and others.—*G. A. Lebedeff.*

ARACHNIDA (EXCEPT ACARINA)

ALEXANDER PETRUNKEVITCH, *Editor*

(See also in this issue Entries 9196, 10177, 11222, 11247, 11752)

11617. **BEIER, MAX.** Pseudoscorpione aus Marocco nebst einer Art von der Insel Senafir. *Bull. Soc. Sci. Nat. Maroc* 10(1/6): 70-78. 5 fig. 1930.—Notes on 11 spp., including: *Obisium* (*O.*) maroccanum* (p. 70) and *Ectoceras* maroccanum* (p. 72), Morocco; *Olpium* gracile* (p. 75), Senafir Isl., Red Sea.

11618. **BEIER, MAX.** Neue Pseudoscorpione der U. O. Neobisiinea. *Mitteil. Zool. Mus. Berlin* 17(2): 299-318. 10 fig. 1931.—*Halobisium* occidentale (p. 299), California, type in Wien Mus.; *Microcreagris* luzonica* (p. 300) and *M.* philippinensis (p. 300), Philippines, types in Berlin Mus.; *M.* chamberlini (p. 301), California, type in Chamberlin coll.; *M.* maroccana (p. 301), Morocco; *Ideobisium* costaricense* (p. 302), Costa Rica, type in Silvestri coll.; **NANNOBISIUM** (p. 303), near *Ideobisium*, type *N.* liberiense* (p. 303), Liberia, type in Wien Mus.; **GYMNOBISIUM** (p. 304), near *Ideobisium*, type *I. quadrispinosum* Tullgren; **MIROBISIUM** (p. 304) (Bochicinae), type *Ideobisium cavimanum* Beier; **DINORONCUS** (p. 305), near *Ideoroncus*, type *Ideobisium* (*Ideoroncus*) *chilense* Ellingsen; **NEGRORONCUS** (p. 305) (Ideoroncinae), type *Ideoroncus africanus* Redikorzev; *Olpium pallipes* balcanicum (p. 305), Levkas Isl., Greece, type in Wien Mus.; *O.* angolensis* (p. 306) [figured as *O. angolense*], Angola (Turkey), type in Berlin Mus.; *Minniza* algerica* (p. 306), Algeria, type in Berlin Mus.; *M.* babylonica (p. 307), Mesopotamia, type in Wien Mus.; **PAROLPIUM** (p. 308), near *Olpium*, type *O. gracile* Beier; *O. arabicum* Sim. and *O. minor* Ell. are referred to *Parolpium; P.* madagascariense (p. 308), Madagascar, type in Berlin Mus.; *Apolpium* minutum* (p. 309), Costa Rica, type in Wien Mus.; **PACHYOLPIUM** (p. 310), type *P.* reimoseri* (p. 310), Costa Rica, type in Wien Mus.; *P.* incertum (p. 311), St. Thomas, W. Indies, type in Berlin Mus.; *P.* erratum (p. 311), Brazil, type in Berlin Mus.; **OLPIOLUM** (p. 312), near *Apolpium*, type *O.* medium* (p. 312), Paraguay, type in Berlin Mus.;

THAUMATOLPIUM (p. 313) (Olpiinae), type *Ideoroncus silvestrii* Beier; PSEUDOGARYPINUS (p. 313), near *Amblyolpium*, type *P.* costaricensis* (p. 314), Costa Rica, type in Wien Mus.; *Geogarypus* formosanus* (p. 315), Formosa, type in Berlin Mus.; *G.* fiebrigi (p. 316) and *G.* paraguayanus (p. 316), Paraguay, types in Berlin Mus.; AFROGARYPUS (p. 317), near *Geogarypus*, type *Garypus senegalensis* Balzan; PROGARYPUS (p. 317) (Garypinae), type *Olpium ramicola* Balzan, also including *O. oxydactylus* Balzan; *P.* novus (p. 318), Brazil, type in Wien Mus.

11619. BERLAND, LUCIEN. Biospeologica. LVI. Campagne spéologique de C. Bolivar et R. Jeannel dans l'Amérique du Nord (1928). 7. Arachnides Aranéides. *Arch. Zool. Exp. et Gén.* 71(3): 383-388. 1931.—The American cave spiders are briefly reviewed, with synonymy, and consist of *Porrhomma* incerta (*Linyphia i.* Emerton) (p. 384); *Phanetta subterranea, Bathyphantes* weyeri (*Linyphia w.* Emerton) (p. 385); *Nesticus carteri*, and *Meta menardi*.

11620. BONNET, P. Remarques sur les "Notes diverses sur les Aranéides" de M. J. Denis. *Bull. Soc. Ent. France* 1931(8): 107-109. 1931.—Notes on the biology of *Zoropsis spinimanus* Duf., *Pholcus phalangioides* Fues., *Argiope bruennichi* Scop., and *Salticus scenicus* Cl.—*S. B. Fracker.*

11621. DAHL, FRIEDRICH. Spinnentiere oder Arachnoidea. I: Springspinnen (Salticidae). In: Die Tierwelt Deutschlands und angrenzenden Meeresteile Pt. 3. pp. 1-55. 159 fig. Gustav Fischer: Jena: 1926.—Contains keys to the German species. The ♂ palpus and the epigynum of each species are figured, the latter from cleared preparations. *Heliophanus* mariae* ♀ (p. 46), Glatzer Mts. Numerous ecological observations are recorded.—*A. Kästner.*

11622. DENIS, JACQUES. Notes diverses sur les Aranéides. *Bull. Soc. Ent. France* 1931(4): 53-59. 1931. —Notes on the habits of the following species, mostly in France: *Zoropsis spinimanus* Dufour, *Scytodes thoracica* Latreille, *Uroctea durandi* Lat., *Pholcus phalangioides* Fuessli, *Latrodectus tredecimguttatus* Rossi, *Argiope bruennichi* Scopoli, *Salticus scenicus* Clerck, and several Argiopidae.—*S. B. Fracker.*

11623. FRANGANILLO, PELEGRÍN. Mas aracnidos nuevos de la isla de Cuba. [More new arachnids of Cuba.] *Mem. Trab. Realiz. Inst. Nacion. Invest. Cien. y Mus. Hist. Nat.* [*Habana*] 1: 45-97. 21 fig. 1929(1930). —Dipluridae: *Ischnothele* longicauda* (p. 47). Theraphosidae: *Leptopalma* arastellatus (p. 48); *L.* cubana (p. 49); *Ischnoculus* denticulatus ♀ (p. 49); BISTRIGUS (p. 51), near *Leptopelma*, type *B.* muticus (p. 51); *Stothis* maculata (p. 51); *Xenesthis* cubana* (*Eurypelma spinicrus* Latr.) (p. 52). Lycosidae: *Lycosa* ovalata (p. 53); *L.* rostrata (p. 53). Theridiidae: *Theridion formosum* v. serratum (p. 53); *Latrodectus* albomaculatus (p. 55); *Theridion* cabriolatum* (p. 56), *T.* fuscum. Pholcidae: *Leptopholcus* delicatulus ♀ (p. 59). Dinopidae: *Dinopus* bituberculatus (p. 59). Argiopidae: *Agyroepeira* pinarensis (p. 59); *A. pulcherrima* v. ochre-rufa (p. 60); *Cyrtognatha* producta (p. 61); *Gea* partita* (p. 61); *G.* integra* (p. 63); *G. subarmata* v. maculata (p. 63); *Meta* linguiformis* ♀ (p. 64); *M.* serrana ♀ (p. 64); *Mangora* triangularis (p. 65); *Eustala* unimaculata (p. 66); *Cubanella* recta* (p. 66); *Cyclosa* elongata (p. 68); *Acusilas* rufonigra (p. 68), *A. r.* var. maculata (p. 68); *Salassina crassicauda* vars. albotuberculata (p. 68) and nigrotuberculata (p. 68); *Araneus fuligineus* vars. romboidalis (p. 69) and sanguineus ♂ (p. 69); *A.* excavatus (p. 69); *A.* aequiangulus* (p. 70), with var. ochraceus (p. 72); *A.* perfoliatus ♀ (p. 72); *A.* anuncinatus (p. 72), with var. depilosus (p. 73); *A.* sulphureus* (p. 73); *A.* fistulosus ♀ (p. 73); *A. nephiloides* v. trapezoidalis ♀ (p. 74); *Micrathena mammillata* v. tuberculata (p. 75); *M.* laminaris (p. 75); *M.* cylindracea (p. 76), with var. argentata (p. 76); *M.* sexacantha (p. 76). Ctenidae: *Ctenus* cruciatus ♀ (p. 77); *C.* impressus ♂ (p. 77); *C.* pilosus (p. 77); *Celaetycheus* fulvorufus (p. 78); *C.* cabriolatus* (p. 78). Thomisidae: *Misumena spinosa* v. olivacea (p. 79). Clubionidae: *Anyphaena* pallidula ♂ (p. 79); *Wulfila* tincta (p. 79); *Corinna* albicans (p. 80); *Stethorrhagus* mandibulatus ♂ (p. 80); *Paratyle* montana (p. 81). Salticidae: *Sarinda* glabra (p. 81); *Emathis* unispina ♀ (p. 82); *Tariona* maculata ♀ (p. 83); *Hassarius* bisetatus (p. 84); *Nagaina* olivacea (p. 85); PARAPLEXIPPUS (p. 85) (Plexippinae), type *P.* sexignatus* ♂ (p. 88), with also *P.* quadrisignatus* (p. 87); *Corythalia* arcuata* (p. 87), with var. fulgida (p. 88); PELEGRINA (p. 88) (Heliophaninae), type *P.* geniculata* (p. 89); *Dendryphantes variegatus* v. limbatus (p. 90); *Menemerus* depressus (p. 90); *M.* fasciculatus* (p. 91); *M.* ochraceus ♀ (p. 91). Pedipalpi, Phrynidae: *Phrynus* pinarensis (p. 92). Scorpiones, Diplocentrinae; *Diplocentrus* trinitarius ♂ (p. 93). It is stated that *Rhopalurus junceus* Poc. is *Scorpio hemprichii* Luc. of Cuban authors. *Rhopalurus junceus* v. ravidus* (p. 95); *Centruroides* subviridis (p. 95). Nineteen spp. new to Cuba, and 29 new localities for spp. already cited are also given.

11624. GUDGER, E. W. More spider hunters. Accounts of arachnids which attack and devour vertebrates other than fishes. *Scientific Monthly* 32(5): 422-433. 9 fig. 1931.—A review of literature concerning arachnids which catch tadpoles, salamanders, frogs, toads, lizards, snakes, birds, and mammals.

11625. HANCOCK, RICHARD. The Aranea or spiders of Hartlebury Common. *Proc. Birmingham Nat. Hist. and Phil. Soc.* 16(2): 45-48. 1931.—A list of 27 spp.

11626. HOLM, Å. Spindelfaunan inom Abisko National-park. Spindlar-Araneae. [The spider fauna within Abisko National Park (Sweden).] *K. Svenska Vetenskapsakad. Skrifter i Naturskyddsärenden* 19. p. 1-9. 1931.—This paper is based on a study of 98 spp. (2500 specimens), of which 86 were taken within the Abisko Nation. Park. *Robertus scoticus, Lephthyphantes nigriventris, Utopiellum mirabile, Erigone psychrophila, E. tirolensis, Titanoeca nivalis, Hahnia mengei*, and *Lycosa norvegica* are new to Sweden.

11627. KÄSTNER, A. Studien zur Ernährung der Arachniden. 2. Der Fressakt von Chelifer cancroides L. *Zool. Anz.* 96(3/4): 73-77. 3 fig. 1931.—The action of the mouth parts of *Chelifer cancroides** in feeding is described.

11628. [PERELESHINA, V. I.] ПЕРЕЛЕШИНА, В. И. Фауна пауков окрестностей Болшевской Биологической станции. [Spiders of the Bolshevo Biological Station, Moscow district.] [English summary.] Записки Биологической Станции Общества Любителей Естествознания, Антропологии и Этнографии в Болшеве Московской губернии. (*Bull. Sta. Biol. Soc. Amis Sci. Nat., Anthrop. et Ethnogr. à Bolchevo, Gouv. Moscou*) 2. 3-74. 1 pl., 8 fig. 1928.—An annotated list of 166 spp. in 76 genera in the families Dictynidae, Drassidae, Pholcidae, Theridiidae, Thomisidae, Clubionidae, Agelenidae, Lycosidae, Oxyopidae, and Salticidae. The nests of the following are illustrated: *Gnaphosa lucifuga, Theridion varians, T. formosum, Linyphia phrygiana*, and *Sitticus floricola*. The reproductive organs of *Laseola torva, Xysticus erraticus, X. ulmi, X. striatipes, Philodromus emarginatus, P. fusco-marginatus, Clubiona reclusa, C. stagnatilis, C. subsultans, Sitticus floricola*, and *Dendryphantes hastatus* are illustrated.

11629. SMEDLEY, N. Notes on king-crabs (Xiphosura). *Bull. Raffles Mus.* 5. [71]-[74]. 1931.—Critical notes on *Tachypleus gigas, T. tridentatus*, and *Carcinoscorpius rotundicauda*.

COLEOPTERA

ANDREW J. MUTCHLER, *Editor*

(See also in this issue Entries 9090, 9176, 10898, 10905, 10906, 10912, 10927, 10928, 10931, 10936, 10945, 10951, 11838)

11630. **ABBOTT, CYRIL E.** The comparative morphology of the spiracles of two species of weevils. *Ann. Ent. Soc. Amer.* 22(2): 331-334. 4 fig. 1929.—In the granary weevil (*Sitophilus granarius*) there is a chamber beyond the spiracle proper, leading to a chitinous bow, followed by a constriction of the trachea and then a wider vestibule in communication with which are 2 tracheal trunks. No muscles are attached to the apparatus and evidence of spiracular closing is lacking. The chamber between the spiracle and the bow differs from a true atrium especially in having tenidia. In the corn billbug (*Sphenophorus maidis*) there is in addition to the heart-shaped spiracular opening a true atrium continuous with a pair of triangular chitinous plates between which there is a slit communicating with the large air chambers. The slit, normally closed, is opened by muscles connecting the apices of the triangular plates. —*M. W. Boesel.*

11631. **BALTHASAR, VLADIMÍR.** Zwei neue Aphodius-Arten (subg. Bodilus) aus Nordafrika nebst einige Bemerkungen über die von mir in Tunesien und Ostalgerien gesammelten Coprophagen. *Ent. Blätter* 25(2): 105-107. 1929.—*A.* (*Bodilus*) **ghardimaouensis** (p. 105), North Africa; *A.* (*B.*) **mařani** (p. 106), Tunisia. Notes on 4 other north African Scarabaeidae.—*M. H. Hatch.*

11632. **BENICK, L.** Drei neue mitteleuropäische Parastenus-Arten nebst Bestimmungstabelle (Col., Staph.). *Ent. Blätter* 25(2): 91-99. 3 fig. 1929.—Key to 12 spp., including *P.* **areolatus** (p. 94, 97), Bergamasker Alps, Italy; *P.* **connatus** (p. 94, 96), eastern Carpathians, Rumania; *P.* **vernaculus** (p. 95, 98), Maritime Alps, France.—*M. H. Hatch.*

11633. **BRADLEY, J. CHESTER.** A manual of the genera of beetles of America north of Mexico. Keys for the determination of the families, subfamilies, tribes, and genera of Coleoptera with a systematic list of the genera and higher groups. [Lithoprinted.] 360p. Daw, Illston and Co.: Ithaca, New York, 1930.—The compiler has selected, rearranged, abbreviated, combined, and translated keys from all the most recent sources, scattered throughout the world's literature on insects. They are dichotomously arranged. The classification is essentially that of Leng's Catalogue (1920), to which page references are given in an appended taxonomic list of genera. There is a full index.

11634. **CAMERON, MALCOLM.** New Staphylinidae from the Malay Peninsula. (Second paper.) *Jour. Fed. Malay States Mus.* 16(1/2): 154-159. 1930.—The new forms are from Malay Peninsula unless otherwise stated. Types of most of them are in author's coll. *Trogophloeus* **malayanus** (p. 154); *Oxytelus* (*Anotylus*) **malayanus** (p. 154); *O. m.* var. **ruficeps** ♂ (p. 154); *Scimbalium* **suturale** (p. 155); *Philonthus* **pendleburyi** ♂ (p. 155); *Staphylinus* **auropubescens** (p. 156); *S.* **subchalceus** (p. 156); *S.* **rufipennis** ♂ (p. 156); *Astilbus* **semicyaneus** (p. 157); *Orphnebius* **politus** (p. 158); *Zyras* **rufithorax** (p. 158), Malay Peninsula and Siam; *Z.* **sparsipennis** (p. 159).

11635. **CAMERON, MALCOLM.** Staphylinidae from British North Borneo, with descriptions of new species. *Jour. Fed. Malay States Mus.* 16(1/2): 160-168. 1930.—The new forms are not all confined to British North Borneo, some being from other parts of Borneo or the Malay Peninsula. The types of most spp. are in the author's coll. A number of previously known spp. are also recorded, with locality and date records. *Lispinus* **unipunctatus** (p. 160); *L.* **borneensis** (p. 160); *Phloeonomus* (s. str.) **crenicollis** (p. 161), *P.* (s. str.) **germanus** (p. 161), and *Oedichirus* **pendleburyi** (p. 162) [type depositories not given]; *Pinophilus* **bettotanus** ♀ (p. 162); *Philonthus* **sericatus** ♀ (p. 162); *P.* **hybridus** ♂ (p. 163); *Staphylinus* **aeneoacreus** ♀ (p. 164); *S.* **aeneipennis** (p. 164); *Naddia* **borneensis** ♀ (p. 165); *N.* **aeneipennis** ♂ (p. 166); *Coproporus minutissimus* v. **nigriceps** (p. 167), Borneo and Malay Peninsula, and *Coenonica* **abdominalis** (p. 167) [type depositories not given]; *Placusa* **cyanescens** ♂ (p. 167); *Zyras* **granulipennis** (p. 167); *Z.* **bettotanus** (p. 168).

11636. **EGGERS, HANS.** Zwei neue Dryocoetes-Arten. *Ent. Blätter* 24(4): 174-175. 1928.—*D.* **samoanus** (p. 174), Samoa; *D.* **rotundicollis** (p. 174), S. Australia.—*M. H. Hatch.*

11637. **EGGERS, HANS.** Zwei neue Blastophagus-Arten (Ipidae, Col.). *Ent. Blätter* 25(2): 103-104. 1929. —Key to 7 spp. of *Blastophagus* including *B.* **brevipilosus** (p. 103), China, and *B.* **starki** (p. 104), Ussuri.—*M. H. Hatch.*

11638. **EGGERS, HANS.** Eine neue Ipidengattung (Col.) aus Nordamerika. *Tijdschr. voor Ent.* 72(1): 40-41. 1929.—**SPHAEROSINUS** (p. 40), near *Dendrosinus* and *Sphaerotrypes*, type *S.* **striatus** (p. 41), type in Zool. Mus. Amsterdam.

11639. **FISHER, W. S.** New Malayan Buprestidae. *Jour. Fed. Malay States Mus.* 16(1/2): 25-57. 1930.—The following are from Malay Peninsula unless otherwise stated. Types are in U. S. Nation. Mus. *Iridotaenia* **insularis** (p. 25); *Exagistus* **atroviridis** (p. 26); *Blepharum* **leopardum** (p. 27); *Chrysopistus* **aeneoviridis** ♀ (p. 29); *Cyphogastra* **malayensis** ♀ (p. 30); *Lampra* **pubescens** (p. 33); *Chrysobothris* **strigicollis** (p. 33), Siam; *C.* **malayensis** (p. 34); *C.* **viduus** (p. 36); *Meliboeus* **angustatus** (p. 37); *M.* **exiguus** (p. 39); *M.* **bicolor** (p. 40); *M.* **insularis** (p. 41); *M. i.* var. **langkawicus** (p. 42); *Agrilus* **malasicus** ♀ (p. 43); *A.* **pendleburyi** ♀ (p. 44), Siam; *A.* **klossi** ♀ (p. 46); *A.* **kedahae** (p. 47); *Coraebus* **semiviridis** (p. 50), Siam; *C.* **kedahae** (p. 51); *Toxoscelus* **speciosus** (p. 53); *Neotoxoscelus* **aeneiventris** (p. 54); *Trachys* **kedahae** (p. 56).

11640. **FISHER, W. S.** New Bornean Buprestidae. *Jour. Fed. Malay States Mus.* 16(1/2): 58-97. 1930.—These are from North Borneo unless otherwise stated; types in U. S. Nation. Mus. *Iridotaenia* **sandakana** (p. 58); *I.* **acutipennis** (p. 59); *Exagistus* **brunneus** (p. 60); *Phrixia* **opulenta** (p. 62), Sarawak; *Neotoxoscelus* **ornatus** (p. 63); *Meliboeus* **melanescens** (p. 65); *Coraebus* **rajah** (p. 66); *Agrilus* **samawangensis** ♂ (p. 68); *A.* **abreui** ♀ (p. 70); *A.* **convergens** ♀ (p. 72); *A.* **brooksi** ♀ (p. 73); *A.* **contractus** ♀ (p. 75); *A.* **bettotanus** ♀ (p. 77); *A.* **kayan** ♀ (p. 78); *A.* **kudatensis** ♂ (p. 80); *A.* **cyanochloris** ♀ (p. 83); *A.* **curtus** (p. 84); *A.* **samboides** ♀ (p. 86); *A.* **kenniah** ♂ (p. 87); *Trachys* **klossi** (p. 89); *T.* **pendleburyi** (p. 91); *T.* **aeneocephalus** (p. 92); *T.* **bettotanus** (p. 94); *T.* **oreophilus** (p. 95).

11641. **FISHER, W. S.** New West Indian Buprestidae (Coleoptera). *Proc. Ent. Soc. Washington* 32(7): 125-129. 1930.—*Polycesta* **insulana** (p. 125), Jamaica; *Psiloptera aurata* v. **domingoensis** (p. 126), Santa Domingo; *Actenodes nobilis*, first record for the West Indies; *Peronaemis* **elegans** (p. 127), Cuba; *Neotrachys* **hoffmani** (p. 128), Porto Rico. Types in U. S. Nation. Mus.

11642. **FRANCK.** [Notes on aberrations of two species of Gyrinus.] *Ent. Blätter* 24(4): 187. 1928.

11643. **GRIDELLI, E.** Risultati zoologici della Missione inviata dalla R. Società Geografica Italiana per l'esplorazione dell'oasi di Giarabub (1926-1927) [Cirenaica]. Coleotteri. *Ann. Mus. Civ. Storia Nat. Genova* 54: 1-487. Map, 1 fig. 1930.—The present study includes also Coleoptera collected by Vito Zanon around Bengasi, and notes on spp. mentioned by other authors, thus constituting a complete record of all Coleoptera thus far known from Cirenaica. The systematic list includes

locality records, notes on frequency and general distribution, and original references of the names of spp. *Bembidion serdicanum* Apflb. is removed from the synonymy of *B. jordanense* Pioch.; *Carterus* (*Macrocarterus*) silvestrii (p. 22); *Laemostenus complanatus* ssp. cyrenaicus (p. 36); *Metabletus impressus* ssp. cyrenaicus (p. 40); *Microlestes* holdhausi* (p. 42); *Omalium* krügeri (p. 61); *Quedius fulgidus* v. erythropygus (p. 77); *Tolyphus* dubius (p. 133); *Merophysia* cyrenaica (p. 139); *M.* andreinii (p. 142), Tripolitania; *Hapalus bimaculatus* v. vittatipennis (p. 183), type in coll. R. Ufficio Agrario Bengasi; *Omophlus* (*Odontomophlus* cyrenaicus ♂ (p. 190); *O. tenellus* Kirsch, emended description; *O.* (*O.*) krügeri ♂ (p. 193), type in coll. Dodero; *O.* (*O.*) *scutellaris* Muls., emended description; key is given to these 4 spp. of *Omophlus; Arthrodeis* confalonierii (p. 196); key is given to the spp. of Tentyriinae of the "8th group of Reitter"; *Oterophloeus* desioi (p. 210); *Schweinfurthia* schusteri (p. 211); key is given to spp. of *Tentyria; T. latreillei* ssp. brachythorax (p. 219); *T.* confalonierii (p. 222); *Adesmia acervata* v. minor (p. 232); key is given to 6 spp. of *Machlopsis; M.* doderoi (p. 235), Lampedusa Is.; *M.* pseudoalata (p. 236); *Stenosis* cugiae (p. 238); *Dichillus* (*Dichillocerus*) cyrenaicus (p. 242); *Scaurus* schusteri (p. 260); key is given to 8 spp. of *Ocnera; O.* cyrenaica (p. 270); key is given to 5 spp. of *Pimelia; P. consobrina* ssp. confalonierii (p. 274); *P.* gestroana (p. 279); *Cabirus* cyrenaicus (p. 290); key is given to 9 spp. of *Scleron; S.* andreinii (p. 295), Tripolitania; *S.* dubium (p. 295); *Scleropatrum* vinciguerrae (p. 297); key is given to the 4 known spp. of *Glaresis; Aphodius* (*Bodilus*) antii (p. 312); *Mnematium ritchiei* ssp. bottoi (p. 324). Unless otherwise stated, all new forms are from Cirenaica, and the types of most are in Mus. Civico Genova; in some cases the type depository is not given. The treatment of some groups is monographic. A table shows the distribution in Cirenaica and neighboring regions of all the 751 spp. mentioned in the catalog. Another table shows the number of spp. from each family which occur in Cirenaica. North Africa is divided into 2 zones, "Africa Minor" and the Sahara. The Sinai Peninsula, Palestine, Mesopotamia, and perhaps a large part of northern Arabia and Persia, can be included with the Sahara to form what the author terms the "eremic" zone, considering that the Cirenaican fauna without doubt belongs to this zone. This fauna is essentially palearctic, including only 29.20% of "circummediterranean" spp., and 45.50% of "eremic" spp. A table of 103 spp. characteristic of the "eremic" subregion is given, with distribution. There is a discussion of the geological history of northern Africa, with its implications for faunistic distribution. There is an index of families, genera, and subgenera.

11644. HELLER, K. M. 7. Bestimmungsschlüssel aussereuropäischer Käfer: Gattung Lophochirus G. A. K. Marshall (Curculionidae). *Ent. Blätter* 24(3): 103-111. 1928.—Key to and notes on 24 spp. of *Lophochirus*, including *L.* circumscriptus (p. 108), New Guinea; *L.* keyensis (p. 109); *L.* aruensis (p. 109), ? Aru; *L.* flexitibia (p. 110), Mindanao; *L.* bisignatus (p. 110), Borneo; *L.* novaeguineae (p. 110), New Guinea; *L.* migrans (p. 110), Java; *L.* basiplagiatus (p. 111), Sumatra; *L.* buruensis (p. 111), Buru; *L.* papuanus (p. 111), New Guinea; *L.* gracilitarsis (p. 107), Sumatra [misprinted as *pracilitarsis* (p. 111)]; *L. apicalis* ab. divisa (p. 109).—*M. H. Hatch.*

11645. HORION. Massenfunde von Stenus kiesenwetteri Ros. [Mass occurrence of S. kiesenwetteri.] *Ent. Blätter* 25(1): 55-56. 1929.

11646. HUBENTHAL, W. Kleine coleopterologische Mitteilungen. *Ent. Blätter* [*Berlin*] 24(2): 88-95. 1 fig. 1928.—The following notes from different authors were gathered together by Hubenthal. WALTER HORN: ♂♂ and ♀♀ of *Meloetyphlus fuscatus* Waterh. were found in 2 different nests of *Euglossa smaragdina* Perty in bamboo in Costa Rica; this large blind beetle is an inhabitant of a very small hole; short diagnosis of ♂ and ♀ is given. P. FRANCK: *Gyrinus natator* ssp. *substriatus* Steph. is the correct name for the beetle hitherto designated *G. natator* L.; *G. n.* ssp. *substriatus* ab. *schatzmayri* Ochs (=*corpulentus* Schatzm.); the true *G. natator* L. (=*mergus* Ahr., *marginatus* Germ., *wankowiczi* Rég.). OCHS: Oct. 1st, very late in the season, there were found near Frankfurt several lampyrid larvae, probably *Phausis splendidula* L. HUBENTHAL: (1) *Anommatus 12-striatus*, reported by Staudinger and Bang-Haas from Dresden, is a synonym of *A. kiesenwetteri* Reitt. (2) *Carabus cancellatus* which has the first joint of antennae black is very rare in Thuringia. (3) *Carabus scheidleri* v. *preyssleri* is found near Breslau, Silesia. VAN EMDEN: *Haltica sandini* Kemner, eastern Prussia, is new to Germany. R. SCHOLZ: (1) *Amara spreta* ab. *nigripes* Schilsky is new to Silesia. (2) Larva (described Ent. Bl. 1926 p. 103) belongs to *Cephennium problematicus*. (3) *Neuraphes talparum* Neresh. and Wagner may be largely distributed around Liegnitz; *Choleva elongata* Payk. new to Silesia. (4) *Meligethes solidus* Kugel, very rare, found at Haasel, Lower Silesia. (5) *Chrysomela sanguinolenta* L. bred from larvae found on small *Veronica* forms. (6) The name of determiner should be used always in connection with the name of the identified form; a label bearing only the name of determiner is worthless. N. KOROTNEW: (1) Notes on a beetle-collecting glass with an automatic cover. (2) Description of an hygienic exhaustor*. (3) Note on investigation of tree-holes with a mirror.—*G. G. Maydell.*

11647. JEANNEL, R. Coléoptères cavernicoles des Carpates méridionales. Rectification. *Bul. Soc. Stiinţe Cluj* [*Rumania*] 5(Fasc. 3, Part 2): 71-72. 1930.—*Duvalius budai* ssp. diószeghyi (*D. diószeghyi* Mallász, =*D. b.* ssp. *micrangulus* Jeannel) (p. 72).

11648. KLEINE, R. Über die Brenthidentypen von Motschoulsky. *Ent. Blätter* 25(1): 51. 1929.—Motschoulsky described only 3 spp. of Brenthidae. 14 unpublished names are included in his collection, the valid names of which are here given.—*M. H. Hatch.*

11649. KLEINE, R. Neue Lyciden der Malaiischen Subregion. *Jour. Fed. Malay States Mus.* 16(1/2): 169-174. 19 fig. 1930.—These spp., except where otherwise stated, are from the Malay Peninsula; types are in British Mus. *Ditoneces* curvicollis* (p. 169); *D.* indistinctus* (p. 169), Malay Peninsula and Borneo; *D.* soror* ♂ (p. 170); *Leptotrichalus* rubrosignatus (p. 170); *Dilophotes* costatus* ♀ (p. 170); *Cautires* selangorensis *♂ (p. 170); XYLOBANELLUS (p. 171), allied to *Conderis* and *Xylobanus*, type *X.* atricolor ♀ (p. 171); *Calochromus* siamensis* (p. 172), Siam; *C.* perakensis* ♀ (p. 172); *Dilophotes* grossus* ♀ (p. 172).

11650. KOLBE, H. Nachtrag zu meinem Artikel über die Carabidomemninen. *Ent. Blätter* 24(3): 125-129. 1928.—The slight differences between the closely related Carabidomemnini (Paussidae) and Ozaenini (Carabidae) are discussed and the paussid *Carabidodoxus* bänningeri (p. 127), Usambara, described.—*M. H. Hatch.*

11651. KOLBE, HERMANN. Foliopaussus, eine neue Untergattung von Paussus. *Ent. Blätter* 25(2): 100-103. 1929.—FOLIOPAUSSUS subg. n. (p. 100) of *Paussus*, for *P. foliicornis* Wasmann (type), which is described, and *P.* hildebrandti (p. 102), Abyssinia.—*M. H. Hatch.*

11652. KOLOSSOW, I. Propylaea 14-punctata L. a. batmanewi nov. ab. *Ent. Blätter* 24(4): 188. 1928.—From Russia (Ural).—*M. H. Hatch.*

11653. KOLOSSEW, J. Was ist Agabus eversmanni Ballion? *Ent. Blätter* 26(2): 85-88. 1930.—Usually interpreted as *A. labiatus* Brahm, this sp. is really a synonym of *A. fuscipennis* Payk.—*M. H. Hatch.*

11654. LENGERKEN, H. von. Langlebigkeit bei Käfern und deren Larven. *Mitteil. Deutsch. Ent. Ges.* 1(6): 84-88. 1930.—The normal age of larvae is 3-4 yrs., although some live 8-45 yrs. The abnormal age is due apparently to lack of moisture rather than to quantity or quality of food, or to the effect of unfavorable temperature conditions on metamorphosis.

11655. LEVER, R. J. A. W. A new endoskeletal organ

in the hind legs of the Halticinae. *Zool. Anz.* 92(9/10): 287-288. 6 fig. 1930.—This organ*, found in *Oxygona, Homophoeta, Disonycha,* and *Asphaera,* is probably a saltatorial modification. It is absent from all the Galerucinae.

11656. MIWA, Y. An enumeration of the coprophagid-Coleoptera from Formosa, with a table of the geographical distribution. *Insecta Matsumurana* 4(4): 163-180. 3 fig. 1930.—List of 101 spp., with descriptions of *Geotrupes laevistriatus* ssp. **formosanus*** (p. 164); *Onthophagus* **sonani*** (p. 171); and *Aphodius* **kotoensis** (p. 174). Types in the Ent. Lab., Research Inst., Formosa.—*R. Takahashi.*

11657. PIC, M. Sur quelques Coléoptères recueillis en Égypte. *Bull. Soc. Roy. Ent. d'Égypte* 14(2/3): 61-64. 1930.—*Centropthalmus* **grandis** (p. 61); *Thorictus* **impressithorax** (p. 62); *T.* **testaceus** (p. 62); **NOTHORHINOMORPHA** (p. 62), based on *N.* **deplanata** (p. 63); *Pogonochaerus perroudi* and *Opilo barbarus,* new to Egypt.

11658. PIC, M. Deux nouveaux Hétéromères de la République Argentine. *Rev. Soc. Ent. Argentina* 3(1): 29-30. 1930.—*Mordella* **ogloblini** (p. 29); *Copidita* **ogloblini** (p. 29).

11659. PLAVILSTSHIKOV, N. N. Über einige Cerambyciden-Arten (Coleopt.). *Ent. Blätter* 25(1): 29-35. 1929.—Descriptions of *Cortodera colchica* Reitt., *Poecilium alni* L., and *Purpuricenus kaehleri* L., and their varieties; *Pogonocherus taygetanus* Pic=*P. eugeniae* Cglb.; *P. eugeniae* v. pici (p. 34), Austria; status of *P. griseus* Pic and *P. hispidus* v. *rufescens* Pic is discussed.—*M. H. Hatch.*

11660. PRELL, HEINRICH. Beiträge zur Kenntnis der Morphologie und Biologie der einheimischen Lochmaea-Arten. *Ent. Blätter* 25(1): 1-11. 1929.—Key to *L. crataegi* Forst., *L. capreae* L., and *L. suturalis* Thoms., with morphological and biological notes on each.—*M. H. Hatch.*

11661. PRETNER, E. Contributo alla conoscenza delle Hydraenae italiane. *Boll. Soc. Ent. Ital.* 62(10): 178-182. 2 fig. 1930.—*Hydraena* (*Haenydra*) **solarii*** (p. 178); *H. truncata* ssp. **falzonii** (p. 181). *H. decolor* Dev., ♂ genitalia figured.

11662. RIBEIRO, S. Notes on some Indian Paussidae with the description of a new species. *Rec. Indian Mus.* 32(3): 223-246. 18 fig. 1930.—A supplement to the work of Fowler, who monographed the family in the "Fauna of British India" series in 1912. The paper is a taxonomic study of those spp. insufficiently treated by Fowler and those described from India since 1912. There are new locality records and observations on the secondary sexual characters of certain spp. The structure of the ♂ genital tube of this family is described for the first time and keys are given for separating the genera and spp. on the basis of this character. Notes, description of ♂ genital tube, and additional localities are given for most of the following: *Ceraptus; C. latipes**, and ssp. *singalensis; C. horsfieldi**; *Pleuropterus; P. taprobanensis**; *Ceratoderus; C. bifasciatus**; *C. andrewesi; Merismoderus; M. bensoni**; *Platyrhopalus; P. denticornis**; *P. angustus; P. intermedius; P. westwoodi; Euplatyrhopalus; E. aplustrifer**; *E. vexillifer**; *Platyrhopalopsis; P. melleyi**; *Platyrhopalides; P. badgleyi**; *Paussus; P. desneuxi; P. spencei; P. cognatus**; *P. hearseyanus; P. sesquisulcatus,* and var. *brevicornis; P. adamsoni**; *P. pilicornis**; *P. fletcheri; P.* **sewelli*** (p. 241), type in Imper. Agric. Res. Inst., Pusa; *P. hardwickei; P. boysi; P. jerdani**; *P. thoracicus; P. tibialis**; *P. nauceras; P. politus; P. escherichi; P. madurensis; P. angustulus.*—*S. Ribeiro.*

11663. SCHILDER, F. A. Zur Variabilität von Adonia variegata Goeze (Col. Coccinell.). *Ent. Blätter* 24(3): 129-142. 1 fig. 1928.—The color variation of each of 204 specimens of this species from Austria is described and the correlation between variation in different parts of the body investigated.—*M. H. Hatch.*

11664. SCHWARZER, BERNHARD. Beitrag zur Kenntnis der Cerambyciden (Ins. Col.). *Senckenbergiana* 13(1): 59-78. 33 fig. 1931.—*Hoplocerambyx* **abnormis*** ♀ (p. 59), Dutch New Guinea; *Massicus* **subregularis*** (p. 60), Sumatra (type) and Borneo; *Dialeges undulatus* ssp. **villosicornis*** (p. 60), Java; **QUETTANIA** (p. 62), near *Anubis,* type *Q.* **coeruleipennis*** ♀ (p. 63), British Baluchistan; *Rhaphuma* **bimaculata** (p. 63), India; *Rhaphuma?* **maculata** ♂* (p. 63), India; *Demonax* **lineaticollis** ♀* (p. 64), Assam; *Ptycholaemus* **longicollis*** (p. 64) and *P.* **variecollis*** (p. 65), Belgian Congo; *P. v.* ssp. **lateralis** ♀* (p. 66), Angola; *Nemophas* **ammiralis*** ♂ (p. 66), Admirality Is. [Melanesia]; *Epepeotes* **soembanicus** ♀* (p. 66), Sumba Is.; *Dihammus* **subauratus** ♂* (p. 68), Borneo; *Choeromorpha* **adspersa*** (p. 68), India; *Tmesisternus* **gabrieli*** (p. 69), Dutch New Guinea; *Niphonoclea?* **longicollis*** (p. 69) and *Acronia* **strasseni** ♂* (p. 70), Philippines; *Cenodocus* **gardneri** ♂* (p. 71), *Pterolophia* **gardneri** ♀* (p. 71), and *P.* **occidentalis** ♂* (p. 72), India; *Lychrosis* **quadrisignatus** ♂* (p. 72), Celebes; *Plocia* **sybroides** ♂* (p. 73), *P.* **ochraceomaculata*** (p. 73), *P.* **subfasciata** ♀* (p. 75), *Cylindroplocia* **helleri*** (p. 76), *Epilysta* **olivacea*** (p. 76), and *Atelais* **basigranosus** ♂* (p. 76), all 6 Philippines; *Glenea* **ochraceolineata** ♂* (p. 77) and *G.* **nobilis*** (p. 78), Borneo. Types in Senckenberg Mus.

11665. TRÄGÅRDH, IVAR. Some aspects in the biology of longicorn beetles. *Bull. Ent. Res.* [*London*] 21(1): 1-8. 6 fig. 1930.—Subjects treated are oviposition, larval tunnels and pupal chambers, the emergence of the adult beetle, and feeding habits of the adults.

11666. UHMANN, E. Berichtigungen zu meinem 3. Beitrag zur Käferfauna Deutschlands. (Ent. Blätter 24: 53-54. 1928.) [Errata for my third contribution to the Coleoptera fauna of Germany.] *Ent. Blätter* 24(3): 143-144. 1928.

11667. URBAN, C. Von der Lebensweise des Lixus myagri Ol. *Ent. Blätter* 24(4): 171-173. 1928.—Oviposition in Germany in early May on the stems of *Barbaraea, Brassica, Nasturtium,* and *Sisymbrium,* in which the larvae mature, usually by August, and transform into adults, in August or September. Notes on the larva. —*M. H. Hatch.*

11668. URBAN, C. Beiträge zur Naturgeschichte einiger Rüsselkäfer II. *Ent. Blätter* 25(2): 65-79. 1929. —Notes on the life cycle, habitat, and immature stages of *Bagous nodulosus, Craponius epilobii, Cidnorrhinus quadrimaculatus, Coeliastes lamii, Allodactylus affinis, Phytobius velatus, Poophagus hopffgarteni, Coryssomerus capucinus, Sibinia potentillae,* and *Orchestes rufus.*—*M. H. Hatch.*

11669. VAN EMDEN, FRITZ. Zwei neue Eptacus aus Syrien (Col. Curc.). *Ent. Blätter* 24(3): 120-124. 1928.—Key to 6 spp. of *Eptacus,* including *E.* **wohlberedti** (p. 120), Transjordania, and *E.* **otiorrhynchoides** (p. 121), Syria.—*M. H. Hatch.*

11670. VOSS, EDUARD. Einige weitere Attelabinae und Apoderinae (Col. Curc.). (26. Beitrag zur Kenntnis der Curculioniden.) *Ent. Blätter* 24(3): 112-120. 1928. —*Euscelus* (*Pheleuscelus*) **fuscus** (p. 112), French Guiana; *E.* (*Eleuscelus*) **subconcolor** (p. 112), Brazil; *Hybolabus* **guyanensis** (p. 113), French Guiana; *Anisolabus* **evanescens** (p. 113), Bechuanaland; *Plassoderinus* **minutus** (p. 114), Congo; *Omolabus* **innotatus** (p. 114), French Guiana; *Paratomapoderus togoensis* ssp. **cordieri** (p. 115), French Congo; *Parapoderus brachypterus* f. **biplagiata** (p. 115), Cameroons; *P.* **patricius** (p. 115), Gabun; *Apoderus* (*Allapoderus*) **collarti** (p. 116), Gabun; *A.* (*Strigapoderus*) **scabrosus** (p. 116), China; *A.* (*Compsapoderus*) **dispar** (p. 117), India; *A.* (*Leptapoderus*) **signatus** (p. 118), China; *A.* (*L.*) **varians** (p. 118), Punjab; *Cycnotrachelus* **parvulus** (p. 119), China.—*M. H. Hatch.*

11671. WASMANN, E. Ein neuer Paussus (P. nobilis) aus Ostindien. (Col. Pauss.) *Mitteil. Deutsch. Ent. Ges.* 1(6): 94-96. 1 pl. 1930.—*P.* **nobilis*** ♂ (p. 94), Central Provs., India, type in Imp. Agric. Res. Inst., Pusa.

11672. ZIMMERMANN, A. Die Dytisciden-Gattung

Lacconectas Motsch. Übersichtstabelle der bekannten Arten nebst zwei Neubeschreibungen. *Ent. Blätter* 25(1): 12-16. 1929.—Key to 10 spp. including *L.* punctipennis (p. 14), Java, and *L.* strigulifer (p. 15), India; *L. festae* Griff. probably belongs to *Aglymbus.*—*M. H. Hatch.*

DIPTERA

E. T. CRESSON, JR., *Editor,* Brachycera

O. A. JOHANNSEN, *Editor,* Nemocera

(See also in this issue Entries 9189, 9196, 9770, 9859, 10619, 10889, 10907, 10936, 10938, 10939, 10940, 10942, 10943, 10944, 10945, 10951, 11582, 11590)

11673. **ALEXANDER, CHARLES P.** New or little known Tipulidae from eastern Asia (Dipt.), VI. *Philippine Jour. Sci.* 42(1): 59-82. 2 pl. 1930.—The present paper is based on the study of the crane flies of the extensive collections made by Syuti Issiki in southern Kiushiu, Yakushima I., south of Kiushiu, and in the mountains of Formosa; also a few spp. from China. Types of new spp. are in author's coll. *Tipula* uénoi* (p. 59), Honshiu, Japan; *Limonia* (*Libnotes*) recurvinervis ♂* (p. 61), Szechwan, China; *L.* (*Geranomyia*) radialis ♂* (p. 62), Kiushiu; *L.* (*G.*) alpestris ♀* (p. 63), Formosa; *L. apicalis* ssp. majuscula (p. 65), and *Helius* (*H.*) chikurinensis ♂* (p. 65) and ssp. minusculus ♂* (p. 66), Formosa; *Tricyphona* baikalica ♂* (p. 66), Baikal, *T.* yakushimana ♂* (p. 67), Kiushiu; *Ula* flavidibasis ♀* (p. 68), Formosa, at 6,500 to 8,000 ft.; *Adelphomyia* ariana* (p. 69), Formosa, 6,500-8,000 ft.; *Pseudolimnophila* chikurina ♂* (p. 70), Formosa; NIPPOLIMNOPHILA (p. 70), resembling *Limnophila,* type *N.* kiusiuensis ♂* (p. 71), *N.* yakushimensis ♂* (p. 72), and *Ulomorpha* polytricha ♂* (p. 72), Kiushiu; *Eriocera* platysoma ♂ (p. 73), Szechwan, China; *Elephantomyia* (*E.*) serotina ♀ (p. 74), Formosa, at 6,000-8,000 ft.; *Ceratocheilus* tinctipennis ♀* (p. 75), Formosa, at 6,500-8,000 ft; *Lipsothrix* yakushimae ♀* (p. 75), Kiushiu; *Gonomyia* (*Ptilostena*) curticellula ♂* (p. 76), Formosa; *G.* (*P.*) shantungensis ♂* (p. 77), Shantung; *Erioptera* (*E.*) ensifera* (p. 78) and *E.* (*Ilisia*) tenuisentis ♂* (p. 79), Formosa; the subg. *Ilisia* is new to Formosa; *E.* (*Empeda*) microtrichiata* (p. 80), Kiushiu; *E.* (*Empeda*) angustistigma ♀* (p. 81), Formosa; *Molophilus* nigritus ♀ (p. 81), Formosa, at 6,500 to 8,000 ft.; *M.* nigritarsis ♀ (p. 82), Formosa.

11674. **AUSTEN, E. E.** A new hippoboscid parasite (Diptera, Pupipara) of the Indian sand-martin. *Ann. and Mag. Nat. Hist.* 5(29): 560-561. 1930.—*Ornithomyia* comosa (p. 560), India, on *Riparia paludicola chinensis* Gray & Hardw. Types in British Mus.

11675. **BURKE, H. E.** Monterey pine midge pupates at bases of needles. *Pan-Pac. Ent.* 6(4): 147. 1930.—Note on *Thecodiplosis piniradiatae.*

11676. **CURRAN, C. H.** New species of Lepidanthrax and Parabombylius (Bombyliidae, Diptera). *Amer. Mus. Novitates* No. 404. pp. 1-7. 1930.—A revision of the genera with keys to the spp. *Lepidanthrax* lutzi (p. 2) and *L.* morna (p. 3), Arizona; *L.* indecisa ♂ (p. 4), Mexico; *L.* panamensis (p. 5), Panama; *Parabombylius* vittatus ♀ (p. 7), Arizona.

11677. **CURRAN, C. H.** Three new Diptera from Canada. *Jour. New York Ent. Soc.* 38(1): 73-76. 1930.—*Hydrophorus* browni (p. 73), Quebec; *Cyrtophloeba* nitida (p. 74), Manitoba; *Meriania* septentrionalis (p. 75), British Columbia. Types in Canadian Nation. Coll. In the material studied were many other dolichopodids previously known only from Alaska, indicating that the Arctic fauna is continuous in distribution around the northern coast of Canada proper, at least as far east and south as the north shore of the Gulf of St. Lawrence.

11678. **DUDA, OSWALD.** Bibionidae. In: **ERWIN LINDNER.** Die Fliegen der palaearktischen Region. 2 (sect. 4): 1-75. 2 pl., 29 fig. (Lief. 45). Schweizerbart'sche Verlagsbuchhandlung: Stuttgart, 1930.—The family and subfamilies, their economic importance etc. are discussed, and keys are given to subfams., genera, and spp. The descriptions include: *Axymyia* kerteszi ♀* "n. sp. or var. of *A. furcata*" (p. 8), Hungary; *Dilophus* rubiginosus ♀ (p. 35), Siberia, type in Vienna Mus.; *D.* strobli (*D. tenuis* v. *minor* Strobl, not *D. minor* Beck.) (p. 36); the larval stages of *Dilophus* are described and figured; also those of *Bibio,* with a note on the larval parasites of the latter; *Bibio* caucasicus ♂ (p. 48), Caucasus, type in Vienna Mus.; *B. clavipes* v. tancrei (p. 50), central Asia; *B.* crassipes ♀* "n. sp. or=*Lautaretensis* Villen." (p. 50), Scandinavia, Finland; *B.* fulvicrus "n. sp. or var. of *fulvicollis* Gimm" (p. 54), Transbaikalia; *B.* handlirschi (p. 56), Austria, Hungary; *B. hortulans* vars. hispanicus and graecus (p. 58), Spain; *B. hortulanus* v. japanicus (p. 59), Japan; *B. h.* var. major ♀ (p. 59), east Asia; *B. h.* vars. nigropilosus and turcmenicus (p. 60), Turkestan; *B. rufipes* v. hungaricus (p. 68), Hungary; *B.* strobli ♀ (p. 69), the Alps. An index to families, subfamilies, tribes, genera, and spp. concludes the paper.

11679. **ENDERLEIN, GÜNTHER.** Zwei neue Toxorhynchites aus dem Kongogebiete. *Zool. Anz.* 94(3/4): 123-125. 1931.—*Toxorhynchites* schultzei ♀ (p. 123), French equatorial Africa, sucking human blood; *T.* tessmanni ♀ (p. 124), Spanish Guinea; *T. conradti* Grünb., ♀ redefined. Types of new spp. in Zool. Mus. Univ. Berlin.

11680. **GALLI-VALERIO, B.** Observations sur les Culicidés, les Tabanidés, les Simulidés et les Chironomidés. *Zentralbl. Bakt. Abt. I.* (*Orig.*) 116(2/3): 220-224. 1930.—Chiefly on local distribution and seasonal development.

11681. **HULL, FRANK M.** Notes on several species of North American Pachygasterinae (Diptera: Stratiomyidae) with the description of a new species. *Ent. News* 41(4): 103-106. 1930.—*Neopachygaster* vitreus (p. 103), Iowa, type in author's coll.; *Eupachygaster punctifer* Malloch, ♂ described.

11682. **LENGERSDORF, FR.** Zwei neue Arten der Familie Lycoriidae (Sciaridae). *Zool. Anz.* 94(3/4): 65-67. 2 fig. 1931.—*Neosciara* röderi ♀* (p. 65) and *Plastosciara* longipennis ♀* (p. 66), Bear Island. Types in Zool. Inst. Univ. Halle.

11683. **LENGERSDORF, FRANZ.** Lycoriidae (Sciaridae). (Conclusion.) In: **ERWIN LINDNER.** Die Fliegen der palaearktischen Region. 2(sect. 7): 33-71. 4 pl., 11 fig. (Lief. 43). Schweizerbart'sche Verlagsbuchhandlung: Stuttgart, 1930.—Keys to spp., and descriptions, including: *Lycoria* corticalis* (p. 38), Germany; *L.* medialis* (p. 51), northern Europe; *L.* pygmaea ♂* (p. 54), central Europe; *L.* insulana and irmgardis* (p. 61), central and northern Europe.

11684. **LINDNER, ERWIN.** Phryneidae. (Anisopodidae, Rhyphidae.) In: **Die Fliegen der palaearktischen Region.** 2(sect. 1a): 1-10. 7 fig. (Lief. 50). Schweizerbart'sche Verlagsbuchhandlung: Stuttgart, 1930.—Discussion of the family and the genera *Phryne* (with key to spp.) and *Mycetobia,* with an annotated list.

11685. **LINDNER, ERWIN.** Petauristidae (Trichoceridae). In: **Die Fliegen der palaearktischen Region.** 2(sect. 1b): 11-22. 12 fig. (Lief. 50). Schweizerbart'sche Verlagsbuchhandlung: Stuttgart, 1930.—Discussion of the family and its morphology, larvae and pupae, and keys to genera and spp., followed by an annotated list of some 20 spp. An index to genera, spp., and vars., and their synonyms concludes the paper.

11686. LINDNER, ERWIN. Blepharoceridae + Deuterophlebiidae. In: Die Fliegen der palaearktischen Region. 2(sect. 2): 1-37. 2 pl., 37 fig. (Lief. 50). Schweizerbart'sche Verlagsbuchhandlung: Stuttgart, 1930.—Contains description of the family, larvae and pupae, keys to genera, and to imagoes and larvae of *Liponeura*, and an annotated list of about 25 spp.

11687. LINDNER, ERWIN. Thaumaleidae. (Orphnephilidae.) In: Die Fliegen der palaearktischen Region. 2(sect. 3): 1-16. 3 pl., 12 fig. (Lief. 50). Schweizerbart'sche Verlagsbuchhandlung: Stuttgart, 1930.—Discussion and description of the family, larvae and pupae, an annotated list of 28 spp., and an index to genera and species.

11688. MARTINI, E. Ein Zwitter von der Gelbfiebermücke. (Dipt.) *Stettiner Ent. Zeitung* 91(1): 83-85. 1 fig. 1930.—A detailed description of *Aedes meigenanus* is given.

11689. MUKERJI, S. Taxonomic importance of the terminal segments of psychodid larvae. *Nature* [*London*] 125(3151): 446-447. 1930.—Specific differences are confined to the 2 terminal segments in the case of *Phlebotomus*, and to only the last segment in *Psychoda*.

11690. ROHDENDORF, B. Caliphorinen-Studien III (Dipt.). Eine neue Rhynchomyia aus Transkaspien. *Zool. Anz.* 88(7/8): 176-179. 1 fig. 1930.—*R.* koschewnikovi* (p. 177), type in Zool. Mus., Univ. of Moscow.

11691. SÉGUY, E. Un nouvel Asilus chinois. (Dipt.). *Ann. Soc. Ent. France* 99(1): 48. 1930.—*A.* sinis, near Peking, type in Mus. Paris.

11692. SPENCER, G. J. Notes on Phalacrocera species, an aquatic crane fly (Diptera, Tipulidae). *Proc. Ent. Soc. Brit. Columbia* 27: 15-16. 1 fig. 1930.—Notes on larvae of *P. vancouverensis** Alex.

11693. STACKELBERG, A. v. Beiträge zur Kenntnis der paläarktischen Syrphiden. II. *Zool. Anz.* 90(3/4): 113-120. 9 fig. 1930.—*Chilosia* lunulifera* (p. 113); *C.* annulifemur* (p. 116); *C.* sichotana* ♀ (p. 118); *Cinxia* dux* ♂ (p. 119). All from the Ussuri region, Siberia; types in Zool. Mus. Russ. Acad. Sci.

11694. TAYLOR, T. H. The blowfly's mouth. *Nature* [*London*] 125(3146): 238. 1 fig. 1930.—A suggestion that the name mouth be applied to to the aperture between the epi- and hypopharynx at the end of the rostrum, rather than to the opening in the center of the terminal disc.

11695. THIEL, P. H. van. Anopheles maculipennis et la variété atroparvus; un problème de l'anophélisme sans paludisme. *C. R. du 2me Congrès International du Paludisme à Alger* [no pp. designated]. 1930; appearing in: *Acta Leidensia, Scholae Med. Tropicae* 5: 193-195. 1931.—Swellengrebel's "race à index alaire plus petit" of *A. maculipennis* is recognized as the var. *atroparvus* (p. 193) of *A. maculipennis* Meigen, the parent spp. being Swellengrebel's "race à index alaire grand." Experiments, including one in which the larvae of both series were fed *Daphnia* powder, fail to sustain Achundow's contention that these "races" are merely forms resulting from different nutrition.

11696. VAN DUZEE, MILLARD C. New species of Dolichopodidae from North America (Diptera). *Ent. News* 41(2): 53-55; (3): 70-73. 1 fig. 1930.—*Rhaphium* latifacies ♂ (p. 53), *R.* longibara (p. 53), *Neurigona* ornatus ♂ (p. 55), *N.* nigrimanus (p. 70), and *Dolichopus* breviciliatus ♂ (p. 71), all from Alberta, types in U. S. Nation. Mus.; *Polymedon* flavitibialis* ♂ (p. 71), Arizona, and *Paraclius* elongatus (p. 72), West Indies, types of both in Univ. Arkansas.

11697. VILLENEUVE, J. Diptères nouveaux de la Somalie italienne. *Boll. Soc. Ent. Ital.* 62(3): 53-55. 3 fig. 1930.—*Sarcophaga* flagellata* (p. 53); *S.* praerupta* ♂ (p. 54); *Blaesoxypha* anceps* (p. 55).

11698. WEHRLE, LAWRENCE PAUL. A note on the food habits of Chyliza erudita Mel. (Diptera). *Jour. Econ. Ent.* 23(1): 286. 1930.—Larva appears to feed on pitch.

HEMIPTERA AND HOMOPTERA

H. H. KNIGHT, *Editor*, Hemiptera

Z. P. METCALF, *Editor*, Homoptera

(See also in this issue Entries 9178, 9196, 10904, 10913, 10918, 10922, 10945, 11754)

11699. BALL, E. D. The toadhoppers of the genus Phylloscelis Germ. (Rhynchota, Fulgoridae). *Canadian Ent.* 62(9): 192-195. 1930.—*Phylloscelis*, key to spp.; *P. atra*, redefined, key to vars., host *Andromeda* sp.; *P. a.* var. ocala (p. 193), Florida; *P.* rubra (p. 194), on *Xolisma fruticosa*, Florida (type), also along coast from Mississippi to New York; *P. rubra* v. nigra (p. 194), Florida; *P. pallescens* on *Andromeda in*, Florida. Types of new spp. in author's coll.

11700. BEAMER, R. H. Some Erythroneura (grape leaf hoppers) of the maculata group (Homoptera, Cicadellidae). *Canadian Ent.* 63(6): 127-135. 1931.—*E. maculata*, ♂ type described; *E.* gillettei (p. 128) and *E.* noncuspidis (p. 129), Illinois; *E.* stephensoni (p. 130), Texas (type), Oklahoma, and Illinois; *E. lunata*, ♂ genitalia described; *E.* contracta (p. 130), Kansas (type), Illinois, and Tennessee; *E.* gemina (*E. maculata* var. *g.* McAtee) (p. 131); *E.* curvata (p. 132) and *E.* impar ♂ (p. 133), Kansas; *E.* brevipes (p. 133), Oklahoma; *E.* nigriventer (p. 134), Illinois; *E.* bifida (p. 134), Louisiana.

11701. BOX, HAROLD E. Algunos Membrácidos de Tucumán y Jujuy. Contribución para un catálogo de las especies argentinas de la familia Membracidae (Hemiptera-Homoptera). *Rev. Soc. Ent. Argentina* 2(5): 217-218. 1929.—A list of Membracidae of these regions, including 9 spp. new to Argentina, with mention of their host plants.

11702. COCKERELL, T. D. A., and ELMER D. BUEKER. New records of Coccidae (Homoptera). *Amer. Mus. Novitates* 424. p. 1-8. 2 pl., 3 fig. 1930.—*Antonina* littoralis ♀* (p. 1), at roots of grass, New Caledonia; LORANTHASPIS (p. 4) (Diaspinae), based on *L.* microconcha ♀*, larva on *Loranthus pentandrus*, parasitic on *Canarium sleeumanum*, Japan; *Ceroplastes* dozieri (p. 7), on *Maytenus buxifolia;* MARSIPOCOCCUS n. subg. (p. 7), presumably in *Lecanium*, based on *Lecanium marsupiale** Green (p. 7). Types in Amer. Mus. Nat. Hist.

11703. DEAY, HOWARD O. Six new species of Tenagobia Bergroth (Hemiptera, Corixidae). *Bull. Brooklyn Ent. Soc.* 25(3): 171-181. 2 pl. 1930.—*Tenagobia* minuta* (p. 171), Panama; *T.* truncata* (p. 172), Ecuador; *T.* mexicana* (p. 174), Mexico; *T.* serrata* (p. 175), Bolivia; *T.* constricta* (p. 176), Ecuador; *T.* hungerfordi* (p. 177), Matto Grosso, Brazil. Types in Univ. Kansas Ent. Coll.

11704. DRAKE, C. J., and H. M. HARRIS. A wrongly identified American water-strider. *Bull. Brooklyn Ent. Soc.* 25(3): 145-146. 1930.—*Gerris rufoscutellatus* does not exist in the United States; *G.* dissortis (p. 145), Ohio (type in Drake coll.), Illinois, Iowa, New York, eastern Canada.

11705. DRAKE, CARL J. Concerning some Tingitidae from the Philippines (Hemiptera), with new species. *Proc. Ent. Soc. Washington* 32(9): 165-168. 1930.—*Paracopium* philippinensis (p. 165), Sibuyan; *Cromerus* bakeri (p. 166), Samar; *C. kalshoveni*, Mindanao, new to Philippines; *C. invarius*, Mindanao and Samar, new to Philippines; *Diplocysta nubilia*, Negros; *Cysteochila pictus*, Borneo, Luzon; *Tingis* buddleiae (p. 168), Luzon, on *Buddleia asiatica*. Types in U. S. Nation. Mus.

11706. GODING, FREDERIC W. Membracidae in the American Museum of Natural History. *Amer. Mus. Novitates* 421. p. 1-27. 1 fig. 1930.—Records are given for 342 spp. **TUMECAUDA** (p. 2) (Centrotinae, Acuminatini), type *T.* **schaefferi** ♀* (p. 3), Arizona; *Bocydium*, key to 5 spp.; *B.* **bullifera** ♀ (p. 4), Bolivia; *Guayaquila* **mirucornua** (p. 7), Honduras; *Umbonia* **octolineata** ♀ (p. 9), Mexico; *U.* **sordida** ♀ (p. 10), Panama; *Alchisme* **elevata** ♀ (p. 10), Bolivia; *Cymbomorpha* **convexa** ♀ (p. 12), *Dysyncritus* **lineatus** ♀ (p. 12), *D.* **nubilus** ♀ (p. 13), and *D.* **discrepans** ♀ (p. 14), Chapada, Brazil; the last named are separated in a key from *D. intectus; Proterpia* **truncaticornis** (p. 15), Chapada; *Poppea* **bulbidorsa** ♀ (p. 17), Peru; *Centrogonia* **speciosa** ♀ (p. 18), Brazil; *Gelastogonia* **gibbera** ♀ (p. 20), Ecuador; *Telamona* **celsa** ♀ (p. 21), Brazil; *Micrutalis* **atrovena** ♀ (p. 22), Costa Rica; *M.* **callangensis** ♀ (p. 22) and *M.* **lata** ♀ (p. 22), Peru; *M.* **tartaredoides** ♀ (p. 22), Bolivia; *M.* **chapadensis** ♀ (p. 23), Brazil; *M.* **tau** ♀ (p. 23), Peru; *Gargara* **discrepans** ♀ (p. 24), Borneo; *Pogon* **flavescens** ♀ (p. 25), N. S. Wales; *Pyrgauchenia* **cornuta** ♂ (p. 26), Borneo; **EUXIPHOPOEUS** (p. 26) (Centrotinae, Centrotini), type *E.* **nodosus** (p. 26), "Dar."

11707. GODING, FREDERIC W. The Membracidae of South America and the Antilles. IV. Subfamilies Hoplophorioninae, Darninae, Smiliinae, Tragopinae (Homoptera). *Trans. Amer. Ent. Soc.* 55(3): 197-330. 2 pl. 1929.—The paper contains keys to all known spp. from South America and the Antilles, with synonymy and habitat. *Umbonia spinosa* v. **sordida** (p. 203), Panama; *Atypa* **bucktoni** (*A. gibba* Buckton, preoc.) (p. 219); *Monobelus flavidus* Fairm. (=*Darnoides semicrema* Baker); *Poppea* **discrepans** (p. 253), Peru; *Micrutalis* **bella** (p. 291); *Acanthicus desmarestii* Laporte is an unknown pupa of some sp. of *Lycoderes.*—*F. W. Goding.*

11708. GRANOVSKY, A. A. A new name for the genus Quippelachnus Oestlund (Aphiidae, Homoptera). *Proc. Ent. Soc. Washington* 32(4): 61-64. 1 fig. 1930.—**OESTLUNDIELLA** (p. 63) (Callipterini), type *O.* flava (*Euceraphis f.** Davidson, =*Quippelachnus "gillettei* Davidson" Oestlund (not *Euceraphis g.** Davidson)); *Euceraphis betulae**.

11709. HOTTES, F. C. Notes concerning the first papers dealing with the aphid fauna of America. *Proc. Biol. Soc. Washington* 44: 61-70. 1931.—The writer gives an English translation of the original descriptions of 36 spp. described by Rafinesque in 1817-1818, and 7 described by Haldeman in 1844, which affect the nomenclature of American aphids. *Aphis diervilla-lutea* Raf. and *A. aralia-hispida* Raf. have not been recognized; *Myzus* **aquilegia-canadensis** (*Aphis a.* Raf.,=? *M. essigi* G. & P.) (p. 62); *Myzus hieracii* (Schrank) (=*A. hieracium-venosum* Raf., *A. campanula-riparia* Raf., *A. hieracium-paniculatum* Raf., *A. annulipes* Raf., *A. verticolor* Raf.); *A. melampyrum-latifolium* Raf. and *A. chenophyllum-canadense* have not been recognized; *A. erigeron-philadelphicum* Raf. (=*A. erigeron-canadensis* Raf.) has precedence over *Macrosiphum erigeronensis* (Thomas); *Myzus persicae* (Sulzer) (=*A. furcipes* Raf.); *A. fusiclava* Raf. is not an aphid; *Macrosiphum rosae* (L.) (=*Aphis rosa-suaveolens* Raf., *A. diplepha* Raf., *A. rhodryas* Raf.); *Aphis viburnicola* Gillette is not a synonym of *A. viburni* Scop.; *A. rumicis* L. (=*A. viburnum-opulus* Raf., *A. viburnum-acerifolium* Raf.); *Rhopalosiphum* **crategus-coccinea** (*A. c.-c.* Raf.,=*R prunifoliae* (Fitch)) (p. 65); *A. cornus-stricta* Raf. (=*A. helianthi* Monell); *Neothomasia* **populus-grandidentata** (*A. p.-g.* Raf.,=*N. populicola* (Thomas)). The description of *Aphis populus-trepida* Raf. appears to apply in part to *Chaitophorus populifoliae* Oestland (Davis); *A. jacobea-balsamita* Raf. (=*A. oreaster* Raf., =*Macrosiphum ambrosiae* (Thomas), *A. xanthelis* Raf., *A. ambrosia* Raf.). *A. erigeron-strigosum* Raf. is synonymous with *Macrosiphum rudbeckiae* (Fitch). *Aphis gibbosa* Raf. is also a synonym of above and is given precedence by Hottes over *A. erigeron-strigosum* although the latter has page precedence. *A. verbena-hastata* Raf., *A. polanisia-graveolens* Raf., *A. arabis-mollis* Raf., *A. polygala-senega* Raf., and *A. acaroides* Raf. have not been recognized; *A. brassicae* L. (=*A. brassica-napus* Raf.). The genus *Loxerates* Raf. with type *A. diervilla-lutia* remains unknown; *Dactynotus* Raf. with type *A. hieracii* Schrank (=*A. hieracium-paniculatum* Raf.) takes precedence over *Myzus* and its subgenus *Neomyzus. Adactynus* Raf. with type *A. pteris-aquilinoides* (=*Macrosiphum ptericolens* Patch) has precedence over *Macrosiphum* Pass. *A. quercus-monticula* Hald. and *A. discolor* Hald. have not been recognized. *Adactynus gibbosa* Raf. (=*Aphis rubecula* Hald.); *Aphis castanea-vesca* Hald. is probably synonymous with and has precedence over *Calaphis castanae* Fitch; *A. pomi* DeGeer (=*A. bicolor* Hald.); *Cinaria pini* (L.) (?=*A. marginipennis* Hald.); *Clavigerus salicis* (L.) (=*A. pilosus* Hald.).

11710. HUNGERFORD, H. B. A new genus of semi-aquatic Hemiptera. *Bull. Brooklyn Ent. Soc.* 24(5): 288-291. 1 pl. 1929.—**MESOVELOIDEA** (p. 288), in Mesoveliidae, based on *M.* **williamsi** ♀* (p. 289), Ecuador, type in author's coll.

11711. HUNGERFORD, H. B. Two new water bugs from the western U. S. A. (Nepidae and Notonectidae). *Canadian Ent.* 62(10): 216-218. 1930.—*Ranatra* **texana** (p. 217), Texas; *Notonecta* **spinosa** (p. 217), Utah (type), Nevada. Types in Univ. Kansas Ent. Mus.

11712. KLYVER, F. D. Notes on the Chermidae. Parts I & II. (Hemiptera: Homoptera). *Canadian Ent.* 62(8): 167-175. 1 pl. 1930; 63(5): 111-115. 3 fig. 1931.—*Trioza albifrons** and *T. urticae* of England are distinct; nymphs of *albifrons* in California are described. *Aphalara calthae,* description of 5th stage nymph*. *Paurocephala* **fremontiae*** (p. 174), California, host plant *Fremontia californica; Synoza pulchar* Laing (=*S. floccosa* Ferris). *Psylla pyricola,* nymphal stages* on *Pyrus persicolor* in New York described; *Psylla mali* nymph* on apple in Nova Scotia described.

11713. KNIGHT, HARRY H. Descriptions of four new species of mimetic Miridae (Hemiptera). *Ent. News* 41(10): 319-321. 1930.—*Coquillettia* **nigrithorax** ♂ (p. 319), Arizona; *C.* **granulata** (p. 319), Utah; *Sericophanes* **albomaculatus** ♂ (p. 320), Texas; *Cyrtopeltocoris* **gracilentis** ♂ (p. 321), Alabama. Types in author's coll.

11714. KNOWLTON, GEORGE F. Notes on Utah Lachnea (Aphididae). *Canadian Ent.* 62(7): 152-161. 6 fig. 1930.—The supertribe Lachnea, and particularly the Lachnini, correspond most closely to a hypothetical ancestral type, feeding on the bark of conifers; the Eulachnini, which are smaller and have remained on the primitive host, attack the needles; the Pterochlorini have gone over to the woody parts of deciduous plants; the Anoeciini have taken on the habit of subterranean summer wingless forms. *Lachnus medispinosus,* which feeds on the bark of twigs of *Pinus contorta;* description of ♀ fundatrix, apterous* and alate* vivipara; *L. brevispinosus* also feeds on *P. contorta; L. solitarius,* description of ♀ apterous vivipara, feeds on younger bark of *Pinus ponderosa; L. edulis** was found on *P. monophylla; L. e.* ssp. **tanneri** ♀ (p. 155), apterous and alate vivipara, Utah, on *P. monophylla; L. hottesi,* description of ♀ apterous* and alate* vivipara, host *Picea engelmanni,* attended by *Formica cinerea* and *F. rufa; L. coloradensis,* description of apterous viviparous and oviparous ♀♀, host *Picea pungens,* attended by *Formica fusca; L. glehnus,* description of apterous viviparous ♀♀, host *Picea pungens; L. curvipes* and *L. occidentalis,* host *A. concolor; L. burrilli* and *L. pulverulens,* host *Juniperus utahensis; Eulachnus rileyi,* host Austrian pine; *Essigella pini,* host lodge pole pine; *Tuberolachnus viminalis,* description of ♀ apterous* vivipara, hosts *Salix alba* and *Acer negundo,* attracting *Vespa occidentalis,* attacked by many syrphid larvae; *Pterochlorus rosae* on rose; *Anoecia querci* on dogwood and grasses.

11715. METCALF, Z. P., and S. C. BRUNER. Cuban Fulgorina. 1. The families Tropiduchidae and Acanaloniidae. *Psyche* 37(4): 395-424. 5 pl. 1930.—A list of

16 spp. with records of localities and dates including: *Neurotmeta sponsa*, nymph figured; *N.* **breviceps** (p. 398), type in Gundlach Mus., Havana; *Neurotmeta* Guerin equals *Tangia Stål;* **TANGELLA** (*Tangiopsis* Melichar, not Uhler) (p. 397), type *Tangia kraatzi* Stal. *Tangia sponsa* Van Duzee (nec Guerin) from Jamaica is referred to *Tangella* (p. 397). *Pelitropis rotulata** Van Duzee, nymph described. The status of the genera *Colgorma* Kirkaldy, *Temora* Kirk., and *Rudia* Stål is discussed. **ACHILORMA** (p. 400), type *Achilius bicinctus* Spinola; *Colgorma fowleriana* Kirk., also referred to *Achilorma* (p. 400); *Colgorma* **montana** (p. 401); *C.* **campestris** (p. 403); *Cyphoceratops furcata** Uhler described; *Remosa spinolae** Guerin, described; *Ladella* **acunae** (p. 405); *Acanalonia servillei** Spinola, described; *A. pumila** Van Duzee, nymph described and illustrated; *A.* **impressa** (p. 408); *A.* **lineata** (p. 411); *A.* **carinata** (p. 413); *A.* **viridula** (p. 414); *A.* **gundlachi** (p. 415); *A.* **insularis** (p. 416). Types, unless otherwise stated, in Metcalf coll., paratypes in coll. Estacion Exper. Agronomica, Cuba.—*Z. P. Metcalf.*

11716. MORDVILKO, A. Les Pemphigiens des Pistachiers et leurs formes anolocycliques. *Bull. Soc. Zool. France* 53: 358-366. 1928.—Nearly every sp. of *Pistacia* has its own sp. of plant-lice of the tribe Fordea (subfam. Pemphiginae); therefore the modern distribution of an anolocyclic form of a heteroecious sp. (living on secondary hosts beyond the limits of distribution of primary ones) indicates the former distribution of the primary host during Tertiary or glacial times. *Forda trivialis* galls are produced on *Pistacia terebinthus*, and its anolocyclic forms (on Gramineae roots) are distributed as follows: Turkestan, the Caucasus, the Crimea, and northwards to central Europe. In Transcaucasia and southern Crimea the sexuparae of this sp. have not entirely disappeared and continue to appear on *Pistacia mutica*, which is not the primary host; this fact indicates that *P. terebinthus* existed there in relatively recent times. *Paracletus cimiciformis* Heyd. (=*Pemphigus pallidus* Derbès). Its galls are formed on *Pistacia terebinthus*, its anolocyclic forms (on Gramineae roots) are distributed over most of Europe, in the Caucasus, in Turkestan, and in Siberia, extending as far as the river Ob (Barnaul). The sexuparae have remained in Transcaucasia and in southern Crimea, which shows that *P. terebinthus* existed there in relatively recent times. *Trifidaphis phaseoli* (=*Tychea groenlandica* Rübsaamen, *Trifidaphis perniciosa* Nevsky, *T. radicicola* Essig) has as its primary host *Pistacia mutica*, on the leaves of which it forms its galls. Its anolocyclic forms are distributed as follows: Turkestan, Egypt, most of Europe (excepting the northeastern part), Greenland, North America, and it is probable that such was the distribution of *P. mutica* in the Tertiary. The galls of *Aploneura lentisci* Pass. are produced on *Pistacia lentiscus*. Its anolocyclic forms are distributed over Turkestan, Egypt, the Caucasus, and most of Europe. *Aploneura* **ampelina** (*Rhizoctonus ampelinus* Mokrz.) (p. 364). This sp. exists now only as an anolocyclic form, for its primary host (probably related to *P. lentiscus*) has possibly entirely disappeared. Its present distribution is the Crimea and Ciscaucasia, on *Vitis vinifera* roots. The 2 spp., *Forda* **hirsuta** (p. 359) and *Slavum lentiscoides*, form galls on the *Pistacia vera* leaves in Turkestan. As to the former sp., only its emigrants and wingless exules are briefly described. The progeny of the emigrants was brought up on *Agropyrum repens* rhizomes, in test-tubes. The exules are not found in Europe, and it may be that *P. vera* never existed in Europe. *Forda follicularia* is recorded from *Pistacia mutica* and *P. terebinthus*. **PEMPHIGETUM** (p. 359), with *P.* **muticae** (p. 359), host *Pistacia mutica; P.* **utricularium** (Pass.) (p. 359), n. comb., host *Pistacia terebinthus.*—*A. Mordvilko.*

11717. MUIR, F. Descriptions and records of Fulgoroidea from Australia and the South Pacific Islands. No. 1. *Rec. Australian Mus.* 18(2): 63-83. 31 fig. 1931.—*Aka* **tasmani*** (p. 63) and *A.* **hardyi** ♂ (p. 64), Tasmania, types in Australian Mus.; *Oliarus* **doddi** ♀* (p. 64), *O.* **hackeri*** (p. 65), *Iolania* **vittipennis*** (p. 66), and *I.* **clypealis** ♂* (p. 67), Queensland; *Tarberus* **jacobii** ♂* (p. 67), New Caledonia; *Nesocharis* **v-nigra** ♀ (p. 68), New Hebrides; *Ugyops* **longiceps*** (p. 69), Queensland; *U.* **sulcata*** (p. 70), and *U.* **buxtoni*** (p. 71), New Hebrides; *U.* **musgravei*** (p. 70), Lord Howe Is., type in Australian Mus.; *Lamenia* **epiensis*** (p. 72), New Hebrides; *Rhinodictya* **granulata** (p. 73), Fiji Is.; *R.* **buxtoni** (p. 73), New Hebrides; *Thaumantia* **insularis** ♀ (p. 74), Solomon Is.; **KALLITAMBINIA** (p. 74) (Tropiduchidae), near *Tambinia*, type *K.* **australia** ♀ (p. 74); *Pseudoparicana* **sanguinifrons** (p. 75), New Guinea [type depository not given]; **LAVORA** (p. 75) [Tropiduchidae], near *Vanua*, type *L.* **ricanoides*** (p. 76), Solomon Is., type in Australian Mus.; *Nisia* **buxtoni*** (p. 77), New Hebrides; **PAINELLA** (p. 77) [Lophopidae], near *Buxtoniella* and *Virgilia*, type *P.* **harti*** (p. 78), Solomon Is.; *P.* **simmondsi*** (p. 80), Solomon Is.; *Plestia* **viridis*** (p. 81), *P.* **minuta*** (p. 82), and *P.* **trimaculifrons*** (p. 82), New Hebrides; *Aprivesa* **varipennis** (p. 83), Western Australia. Types are in British Mus., unless otherwise noted.

11718. TAKAHASHI, RYOICHI. List of the aphid genera proposed as new in recent years. *Proc. Ent. Soc. Washington* 32(1): 1-24. 1930.—This list of 110 names is supplementary to A. C. Baker's 1920 list of aphid genera. *Pterochlorus* Rond. (=*Maculodryaphis* Gaumont); *Glyphina* Koch (=*Kurisakia* Tak.); *Sappocallis* Matsumura (=*Telocallis* Shinji); *Myzocallis* Pass. (=*Pteriaphis* Gaum., *Melanocallis* Oestl., *Tinocallis* Mats., *Tuberocallis* Nevsky, *Mesocallis* Mats., *Neocallis* Mats., *Sarucallis* Shinji, *Lutaphis* Shinji); *Myzocallis kahawaluokalani* Kirk. (=*Sarucallis lythrae* Shinji); *Myzocallis yokoyamai* Takah., *M. querciformosanus* Takah., *M. nigra* Okam. and Takah., and *M. pilosus* Takah. are referred to *Recticallis; Euceraphis* Walk. (=*Quippelachnus* Oestl.); *Thripsaphis* Gillette (=*Allaphis* Mordvilko); *Drepanaphis* Del Guercio (=*Mimocallis* Mats., *Betacallis* Mats.); *Clavigerus* Szépl. (=*Plocamaphis* Oestl.); **PAOLIELLINA** (p. 7), new subtribe in Callipterini, for *Paoliella; Eutrichosiphum* Essig & Kuwana (=*Goodea* Shinji); *Cervaphis* van der Goot (=*Diverosiphum* Shinji); *C. quercus* Takah. (=*Diverosiphum kunugii* Shinji); *Setaphis* van der Goot (=*Cerciaphis* Theobald); *Neoacaudus* Theobald (=*Amphicercidus* Oestl.); *Anuraphis* Del Guercio (=*Cedoaphis* Oestl., *Xerobion* Nevsky, *Ceruraphis* Börner, *Lachnaphis* Shinji); *Longicaudus* van der Goot (=*Hemiaphis* Börner); *Cerosipha* Del Guercio (=*Aphidula* Nevsky); *Cryptosiphum* Buckton (=*Pseudolachnus* Shinji); *Xerophilaphis* Nevsky is a synonym of *Brachyunguis* Das and apparently also of *Pergandeidia* Schout.; *Neaphis* Nevsky is a synonym of *Stephensonia* Das, and probably of *Rhopalosiphum* Koch; *Rhopalosiphum lahorensis* Das (=*Neaphis viridis* Nevsky); *Vesiculaphis* Del Guercio (=*Trilobaphis* Theob.); *V.* **theobaldi** (*Trilobaphis caricis* Theob., not *V. c.* Fullaway (p. 12); *Macrosiphum* Pass. (=*Tritogenaphis* Oestl., *Sitobion* Mordv., *Staticobium* Mordv., *Paczoskia* Mordv., *Anameson* Mordv., *Metopolophium* Mordv.); the type of *Staticobium* is selected as *S. otolepidis* Nevsky; *Macrosiphum neoartemisiae* is referred to *Titanosiphon; Megoura* Buckton (=*Tuberosiphum* Shinji); *M. citricola* van der Goot (=*T. camphorae* Shinji); *Amphorophora* Buckton (=*Clavosiphum* Shinji); *Capitophorus* van der Goot (=*Cryptomyzus* Oestl.); *Hyalopteroides* (=*Hayhurstia* Mordv., not Del Guercio); *Forda Heyden* (=*Hemitrama* Mordv.). The bibliography contains 77 references.

11719. THEOBALD, FRED. V. Three new British aphides. *Entomologist [London]* 61(776): 8-10. 3 fig. 1928.—*Macrosiphoniella* **triglochiniella*** (p. 8), apterous viviparous* and alate viviparous* ♀♀ on *Triglochin maritimum; Neoacaudus* **inflatus*** (p. 9), apterous viviparous ♀ on *Artemisia vulgaris; Aphis* **palustris*** (p. 10), apterous viviparous ♀, on *Triglochin palustris.* Types in author's coll.

HYMENOPTERA

C. F. W. MUESEBECK, *Editor*

(See also in this issue Entries 9150, 9178, 9193, 9408, 10005, 10934, 10945, 10947, 10948, 10949, 10951, 10967, 10972, 10973, 10974, 10979, 10980, 10985, 10986, 11582, 11590, 11866)

11720. **ANDREWS, E. A. Populations of ant mounds.** *Quart. Rev. Biol.* 4(2): 247-257. 1929.—In Europe, actual counts of the ants in their nest mounds have been few and have shown at most about 100,000 ants; however, authorities have surmised that the populations may run up to 500,000. In America, the count of ants from one average mound of *Formica exsectoides* F. and certain calculations give a mere 10,000 as the entire ant population when in the state of hibernation within and beneath one mound; though data lead to the assumption of such numbers as 50,000 for a very large mound. These mounds thus have a population much like that of the beehive; and not comparable to the much greater population of some termite dwellings.—*E. A. Andrews.*

11721. **BALDUF, W. V. The bionomics of Tetrastichus verrucarii (Chalcidoidea) with notes on its hosts (Neuroterus spp., Cynipidae) on bur oak.** *Canadian Ent.* 61 (6): 125-130. 1929.—The observations here recorded extend the known hymenopterous fauna of *Quercus macrocarpa* by 4 or more species.

11722. **BENSON, ROBERT B. On the occurrence of the sawfly Arge ciliaris L. in Britain.** *Ent. Month. Mag.* 66(792): 113-114. 1930.

11723. **BEQUAERT, J. Some additional remarks on the masarid wasps (Hymenoptera).** *Psyche* 36(4): 364-369. 1929.—Attention is called to a recent paper by A. v. Schulthess, describing new African spp. and one new genus; also to a paper by C. H. Hicks on the habits of *Pseudomasaris.* The value of certain venational characters is discussed. In all Masaridinae the marginal cell of the fore wing is more or less truncate at the apex. A brief account is given of the fossils that have been referred to the Diploptera. It is concluded that *Palaeovespa gillettei* Ckll. is probably diplopterous and most likely belongs in one of the social subfamilies, though doubtfully one of the Vespinae; *Odynerus praesepultus* is doubtfully diplopterous; while *Odynerus palaeophilus* does not belong to the Diploptera.—*J. Bequaert.*

11724. **BLÜTHGEN, P. Neue turkestanische Halictus-Arten. (Hym. Apidae).** *Konowia* 8(1): 51-86. 10 fig. 1929.—*Halictus* **tadschicus** (p. 51), type in Brit. Mus.; *H.* **korbi*** (p. 55), type in author's coll.; *H.* **quettensis** (p. 58), type in Brit. Mus.; *H.* **skorikovi*** (p. 61), type in Leningrad Mus.; *H.* **alanus** (p. 64), type in A. Lebedev (Kiev) coll.; *H.* **testaceohirtulus*** (p. 65), type in Jaroslaw Mus.; *H.* **pseudaraxanus** (p. 70) and *H.* **anguligularis*** (p. 72), types in author's coll.; *H.* **gussakovskii*** (p. 74), type in Jaroslaw Mus.; *H.* **subauratovestitus** (p. 80) and *H.* **bulbiceps** (p. 81), types in author's coll.; *H.* **mordacellus** (p. 84), type in the U. S. Nat. Mus. The ♂ of *H. scutellaris* Mor. is described for the first time; *H. araxanellus* Blüthg. is redescribed, *H. mongolicus* Mor. ♀ is redescribed and the ♂ described for the first time; the ♂ of *H. desertorum* is described for the first time.—*C. E. Mickel.*

11725. **CHEESMAN, L. EVELYN. Hymenoptera collected on the "St. George" expedition in Central America and The West Indies.** *Trans. Ent. Soc. London* 77(2): 141-154. 9 fig. 1929.—An annotated list of 77 spp., including: *Tetrapedla* **acuticollis*** ♀ (p. 142), Colombia; *Xylocopa darwini* Ckll. is figured; *Euglossa* **cupreiventris*** ♀ (p. 146), Panama; *E.* **gorgonensis*** ♀ (p. 146) and *E.* **granti*** ♀ (p. 147), Gorgona Is., Colombia; *E.* **championi*** ♂ (p. 148), Panama.

11726. **COCKERELL, T. D. A. Descriptions and records of bees. 119.** *Ann. and Mag. Nat. Hist.* 4(21): 296-304. 1929.—*Sphecodes* **levequae** ♀ (p. 296), *Nomada* **semirugosa** ♀ (p. 297), *Colletes* **cauponarius** ♀ (p. 298), *C.* **rufocinctus** ♂ (p. 298), and *C.* **nitidicaudus** ♂ (p. 299), Colorado; *Augochlora* (*Odontochlora*) **seitzi** ♀ (p. 299), Brazil; *Andrena* **timberlakei** (p. 300), California. The paper also gives a list of spp. of Xylocopidae from Siam, including: *Mesotrichia latipes* v. **magnifica** (p. 302); *Xylocopa iridipennis* v. **semipurpurea** (p. 302); *X. auripennis* v. **phenachroa** ♀ (p. 303); *Mesotrichia* **kerri** ♀ (p. 303).

11727. **COCKERELL, T. D. A. African bees of the genus Megachile.** *Ann. and Mag. Nat. Hist.* 6(34): 512-519. 1930.—*Megachile* **andersoni** ♀ (p. 512) and *M.* **ritchiei** ♀ (p. 513), Tanganyika Terr.; *M. pennata* Smith is removed from the synonymy of *M. maxillosa* Guérin; *M.* **mombasica** ♀ (p. 515), Kenya Colony; *M.* **leonum** (p. 516), Tanganyika Terr.; *M.* **mediorufa** (p. 516), Sudan; *M.* **masaiella** ♀ (p. 518), Kenya Colony; *M.* **bedfordi** ♂ (p. 518). Types in Brit. Mus. There are distributional and taxonomic notes on a number of previously known spp.

11728. **COCKERELL, T. D. A. Wasps of the genus Cerceris in the Queensland Museum.** *Mem. Queensland Mus.* 10(1): 32-36. 1930.—*Cerceris* **hackeriana** (p. 32), N. S. Wales; *C.* **goddardi** (p. 33), *C.* **darrensis** ♀ (p. 34), *C.* **brisbanensis** ♀ (p. 35) and *C.* **goodwini** ♀ (p. 35), Queensland.

11729. **COLLART, A. Sur la biologie de deux Hyménoptères congolais.** *Rev. Zool. Bot. Africaines* 16(4): [55]-[58]. 1929.—An abstract, referring to *Philanthe apivore,* parasitic on the honey bee, and to *Cerceris* sp., parasitic on Buprestidae.

11730. **DAKESSIAN, V. S. Variation and correlation on the legs of the honeybee.** *Ann. Ent. Soc. Amer.* 22(2): 168-174. 1 fig. 1929.—Considering only the femora and tibiae of all the legs and the 1st tarsal joint of the 3rd leg, the most variable segment is the 1st tarsal joint of the hind leg and the least variable are the tibia and femur of the 3rd leg. The width of the segments is more variable than the length. The highest correlation is found between the bilaterally symmetrical joints. Correlation between segments of one leg is higher than correlation between similar segments of different legs. There is no correlation between the length and width of the same segments. A list of references is given.—*M. W. Boesel.*

11731. **DONISTHORPE, HORACE. Cardiocondyla bicolor, sp. n. (Hymenoptera, Formicidae), a species of myrmecine ant new to science.** *Ann. and Mag. Nat. Hist.* 6(33): 366. 1930.—*Cardiocondyla* **bicolor** ♀ (p. 366), Palestine, on *Ficus sycamorus;* type in Brit. Mus.

11732. **FOUTS, ROBERT. A new species of Microphanurus from Italian Somaliland (Hym. Scelionidae).** *Boll. Soc. Ent. Ital.* 62(6): 118-120. 1 fig. 1930.—*Microphanurus* **aloysii-sabaudiae*** (p. 118), from *Nezara viridula* and *N. pallidoconspersa.*

11733. **FRIESE, H. Die Schmarotzerbienengattung Osiris Sm. (Hym.).** *Stettiner Ent. Zeitung* 91(1): 103-127. 5 fig. 1930.—A monograph of the 34 spp. of this genus which inhabit the American tropics and are parasitic on bees of the genus *Tetrapedia.* A key to species is given. *O.* **duckei*** (p. 112); *O.* **carinicollis** (p. 113); *O.* **fasciatellus** ♂ (p. 115); *O.* **nigrocinctus** ♀ (p. 115); *O.* **polybioides** ♂ Ducke i. l. (p. 115); *O.* **atriventris** ♂ (p. 116), Bolivia; *O.* **collaris** ♂ (p. 116); *O.* **angustipes** (p. 117); *O.* **analis** ♂ (p. 117); *O.* **nigriventris** (p. 117); *O.* **paraënsis** ♂ (p. 118); *O.* **boliviensis** (p. 118), Bolivia; *O.* **ferrugineus** (p. 118), Bolivia; *O.* **flavus** ♂ (p. 119), Peru; *O.* **nitidicollis** (p. 120); *O.* **latitarsis** (p. 120); *O.* **longiceps** ♂ (p. 120), Bolivia; *O.* **longipes*** (p. 122); *O.* **flavofasciatus** (p. 123); *O.* **rutilans** ♂ Klüg i. l. (p. 123); *O.* **fulvicornis** ♂ (p. 123); *O.* **acutiventris** ♀ (p. 124); *O.* **notaticollis** ♂ (p. 125). Except where otherwise given, new spp. are all from Brazil. Types in Berlin Mus.—*H. Friese* (*transl. by P. H. Timberlake*).

11734. **HABERMEHL, H.** Neue und wenig bekannte paläarktische Ichneumoniden (Hym.). [To be concl.] *Konowia* 8(3) : 257-267. 1929.—Brief notes and records of 65 spp. of Ichneumoninae and Cryptinae. *Ichneumon* sieberti (p. 259) and *I.* solitarius (p. 259), Russia; *Amblyteles? palliatorius* f. subniger (p. 260); *Platylabus? nigricollis* f. discedens (p. 260), and *Spilocryptus* gracilentus (p. 264), Germany; *S.* uffelni (p. 265), Switzerland; *Microcryptus* hedwigi (p. 266), Germany. Types in the author's coll.—*C. E. Mickel.*

11735. **HEINRICH, G.** Bemerkungen über die Ichneumoninae in Brischkes Sammlung zu Danzig. *Konowia* 8(1) : 7-8. 1929.—*Hepiopelmus longicornis* Br. ♂=*Platylabus* sp. ♂; *Phaeogenes aries* Br. ♀=*Diadromus guttulatus* Grav. ♀; *Phaeogenes rufipes* Br. ♀=*Centeterus confector* v. *opprimator* Grav. ♀; *Phaeogenes pulchricornis* Br. ♀=*P. ophtalmicus* Wesm. ♀. There are additional notes regarding the identity of certain specimens in the Brischke coll.—*C. E. Mickel.*

11736. **HEINRICH, G.** Beiträge zur Systematik der Ichneumoninae. *Konowia* 8(1) : 13-17. 1929.—*Coelichneumon wormatiensis* Haberm. ♀=*Stenichneumon dorsosignatus* Berth. ♀; *Ichneumon comitator* L. is the same as *I. lineator* Grav. and the author thinks that *Coelichneumon comitator* auct. is probably the same as *C. derasus* Wesm.; there are notes on *Euichneumon sarcitorius* ssp. *turkestanicus* Heinr. ♂, *Melanichneumon fortipes* Wesm. ♂, and *Amblyteles equitatorius* ssp. *carnifex* Kriechb. ♂. *Stenichneumon sordidus* Wesm. ♀=*S. personatus* Grav. Characters are indicated by which the ♂♂ of *Barichneumon sicarius* Grav. and *rufifrons* Grav. may be separated. *Euichneumon albiger* v. polonicus (p. 14), Poland; the ♂ of *Platylabus gigas* Kriechb. is described.—*C. E. Mickel.*

11737. **HEINRICH, G.** Die Wirte einiger Ichneumoniden. *Konowia* 8(3) : 319-320. 1929.—Host records for 16 spp. of Ichneumonidae.—*C. E. Mickel.*

11738. **HENSCH, A. H.** Beitrag zur Kenntnis der jugoslavischen Ichneumonidenfauna. [To be concl.] *Konowia* 8(2) : 123-153. 1929.—Treats the tribe Pimplini, genera *Pimpla* Fabr. and *Troctocerus* Woldst; 47 spp. of *Pimpla* and 1 of *Troctocerus* are recorded, and keys presented for their identification. *Pimpla angens* v. simulans (p. 127), *P.* dumeticola (p. 129), *P.* obscuripes (p. 129), *P.* divergens (p. 129), *P. nigriscaposa* v. ribesii (p. 129), *P.* salicicola (p. 130), *P.* singularis (p. 130), *Troctocerus* zagoriensis (p. 132), *Ephialtes* tener (p. 140), *E.* discrepans (p. 146), *E.* incertus (p. 150), *E.* vernalis (p. 153).—*C. E. Mickel.*

11739. **HICKS, CHARLES H.** Pseudomasaris edwardsii Cresson, another pollen-provisioning wasp, with further notes on P. vespoides (Cresson). *Canadian Ent.* 61(6) : 121-125. 1929.—Biological notes including nest architecture, parasites and behavior.

11740. **HOFFMEYER, E. B.** Neue und wenig bekannte Callimomiden aus Suedeuropa, hauptsaechlich Italien (Hym. Chalc.). *Boll. Soc. Ent. Ital.* 62(6) : 114-117. 1930.—This paper is based upon collections in the Mus. Civico of Genoa and in the Zool. Mus., Copenhagen. A list of 17 spp. is given, with locality records and taxonomic remarks. *Callimome* schiödtei ♀ (p. 115), Italy, type in Mus. Zool., Copenhagen; *C.* scoparii ♀ (p. 116), from *Asphondylia sarothamni,* France and Italy, type in Mus. Civico, Genoa.

11741. **KUZNETZOV-UGAMSKIJ, N. N.** Die Ameisen des Süd-Ussuri-Gebietes. *Zool. Anz.* 83(1/4) : 16-34. 5 fig. 1929.—The present paper has been published in Russian by the author. It contains an annotated list of 30 spp., with emended descriptions.

11742. **KUZNETZOV-UGAMSKIJ, N. N.** Die Ameisenfauna Daghestans. *Zool. Anz.* 83(1/4) : 34-45. 3 maps, 1 fig. 1929.—A list of the 60 spp. known to Daghestan, Caucasus, including: *Formica rufibarbis* v. montaniformis (p. 39).

11743. **LEBEDEV, A. G.** Neue Biene-Arten aus S.S. S.R. *Konowia* 8(3) : 268-272. 1 fig. 1929.—The following bees are reported from Soviet Russia: *Anthidium* (*Proanthidium*) *transcaspicum* Lebed., descriptive notes; *Andrena* eburneoclypeata (p. 268); *Dasypoda* vulpecula* (p. 269). Types in author's coll.—*C. E. Mickel.*

11744. **LUBBOCK, Sir JOHN (Lord AVEBURY), and J. G. MYERS** (with plates by A. J. E. Terzi). Ants, bees and wasps: a record of observations on the habits of the social Hymenoptera. new ed. 377p. 6 pl. E. P. Dutton & Co.: New York; Kegan Paul & Co.: London, 1929. $3.75.—This edition contains notes by J. G. Myers which give more recent contributions on the problems discussed by Lubbock, including quotations from such authors as von Frisch, Kühn, Eidmann, Forel, Donisthorpe, and Wheeler.—*F. G. Wallace.*

11745. **LYLE, G. T.** Contributions to our knowledge of the British Braconidae. 11. Calyptinae. *Entomologist* [*London*] 62(793) : 123-129. 1929.—Diagnostic list of the Calyptinae with keys to the genera and species.

11746. **MASI, L.** Descrizione di un'Allodape viventi nelle spine di un'acacia nella Somalia Italiana. [An Allodape living in the spines of an acacia in Italian Somaliland.] *Mem. Soc. Ent. Italiana* 9(1) : 67-75. 2 fig. 1930.—*Allodape* strandi* (p. 68), from spines of *Acacia fistula* Oliv., type in Genoa Nat. Hist. Mus. The larva* also is described.

11747. **MENOZZI, C.** Formiche della Somalia Italiana Meridionale. [Ants of southern Italian Somaliland.] *Mem. Soc. Ent. Italiana* 9(1) : 76-130. 3 pl., 4 fig. 1930. —This paper treats of 54 forms, with synonymies and notes on taxonomy and ecology. *Phcidole variolosa**, first description of soldier; *Cardiocondyla emeryi* ssp. chlorotica ♀ & ♀ (p. 84); *Crematogaster* (*Acrocelia*) aloysii-sabaudiae* ♀ (p. 86), from spines of *Acacia bussei; C.* (*A.*) *chiarinii* v. *aethiops,* first description of ♂; *C.* (*A.*) *gerstäckeri** Dalla Torre, emended description; *C.* (*A.?*) *rivai* v. luctuosa* ♀ (p. 96); *C.* (*Sphaerocrema*) paolii* ♀ (p. 102); *C.* (*Decacrema*) *solenopsides,* first description of ♂; key to workers of *Crematogaster* so far found in Italian Somaliland; *Tapinoma* chiaromontei* ♀ (p. 113); *Camponotus* (*Tanaemyrmex*) *somalinus,* first description of ♂; *C.* (*Myrmotrema*) *ilgi,* first description of ♀. A list of 73 spp., subspp., & var. found to date in Italian Somaliland is appended.

11748. **MEYER, N. F.** Zur Ichneumonidenfauna von Chiva und Buchara. *Konowia* 8(1) : 18-26. 1929.—Seventy spp. of Ichneumonidae are listed from this region including: *Enicospilus* abnormis (p. 19); *Ophion* buchariensis (p. 20); *O.* cephalotes (p. 20); *Trichomma* cingulata (p. 21); *Erigorgus villosus* v. nigripes ♀ (p. 21); *Labrorychus amabilis* v. chivensis (p. 22); *Paniscus* nigridorsum (p. 23); *Exetastes* rufiventris (p. 23); *E.* gussakovskii (p. 23); *E.* pillosus (p. 24); *E.* paradoxus (p. 25); *Cremastus* zimini (p. 25).—*C. E. Mickel.*

11749. **MICHELI, LUCIO.** Note biologiche e morfologiche sugli Imenotteri. (Contributo 2°.) [Biological and morphological notes on Hymenoptera.] *Mem. Soc. Ent. Italiana* 9(1) : 46-66. 6 pl., 1 fig. 1930.—Detailed descriptions of nests and larvae of *Odynerus* (*Ancistrocerus*) *oviventris** (Wesmael); *O.* (*Hoplopus*) *spinipes* v. *alpina**; *Crabro* (*Coelocrabro*) *cinxius** Dahlbom; *Psen pallipes** (Panz.); *Pemphredon* (*Cemonus*) *unicolor** (F.); and *Osmia leucomelaena** (Kirby). The nest of the first is figured.

11750. **MORLEY, CLAUDE.** Cornish Hymenoptera-Parasitica. *Entomologist* [*London*] 62(792) : 113-114. 1929.—List of 79 spp.

11751. **MORLEY, CLAUDE.** A sawfly new to Norfolk. *Ent. Month. Mag.* 66(790) : 62-63. 1930.—*Arge ciliaris* L., captured on marsh vegetation, is very rare in Britain.

11752. **NIELSEN, E.** A second supplementary note upon the life histories of the Polysphinctas (Hym. Ichneum.). (In English.) *Ent. Meddel.* [*Copenhagen*] 16(7) : 366-368. 2 fig. 1929.—Two ichneumon-fly larvae were found in an egg-cocoon of the spider *Segestria senoculata.* From one of these larvae (only one pupated), a ♀ *Clistopyga oncitator* F. emerged. The author is of the opinion that *Clistopyga* parasitizes spiders only.

11753. **NIXON, G. E. J.** The Ethiopian representa-

tives of the genus Galesus (Proctotrupoidea), with descriptions of new species. *Ann. and Mag. Nat. Hist.* 6(34) : 399-414. 1930.—This paper is based mainly on collections made by R. E. Turner. All new forms are from the Union of S. Africa, and the types are in the Brit. Mus. An emended diagnosis of the subgenus *Schizogalesus*, which includes all the spp. herein described, is given. There are keys to the ♂♂ and the ♀♀ of the various spp. *Galesus* quadridens (p. 402); *G.* bidens (p. 403); *G.* inquisitor (p. 404); *G.* distinctus (p. 405); *G.* rectangularis (p. 406); *G.* abdominalis (p. 406); *G.* magnificus (p. 408); *G.* modestus (p. 408); *G.* turneri (p. 409); *G. t.* var. carinaticeps (p. 410); *G.* longiceps (p. 410); *G.* silvestrii (p. 411); *G. s.* vars. nigricornis and robustior (p. 412); *G.* difficilis (p. 412); *G.* muscidorum (p. 413); *G.* punctulatus (p. 414); *G.* conradti (p. 414).

11754. **OGLOBLIN, A. A.** A new species of Telenomus parasite of Hysteropterum liliimacula Costa. *Mem. Soc. Ent. Italiana* 9(1) : 41-45. 3 fig. 1930.—*T.* sacchii* (p. 41), Italy.

11755. **ÖKLAND, FRIDTHJOF.** Wieviel "Blattlauszucker" verbraucht die rote Waldameise (Formica rufa)? *Biol. Zentralbl.* 50(8) : 449-459. 1930.—Three trees (*Betula verrucosa*, *Pinus silvestris*, and *Picea excelsa*), each visited by a different colony of red ants, were investigated. Equal numbers of descending and ascending ants were collected, dried, and weighed. The average excess in weight of a descending individual over an ascending individual was about 1 mg. Thus, with an estimated number of 500 visits per season, the average seasonal consumption of honeydew per ant would be 5 g. If ½ of the 100,000 inhabitants of a nest fetch honeydew, their seasonal consumption would amount to 10 kg. Thus honeydew is of great importance to *Formica rufa*. *Lasius niger* makes still greater use of this substance. The amount consumed by a colony of *F. rufa* compares favorably with the honey production of a swarm of bees.

11756. **PANDAZIS, GEORG.** Über die relative Ausbildung der Gehirnzentren bei biologisch verschiedenen Ameisenarten. *Zeitschr. Wiss. Biol. Abt. A, Zeitschr. Morph. u. Ökol. Tiere.* 18(1/2) : 114-169. 26 fig. 1930. —Measurements were made of the brain centers in species of ants that differ biologically. It thus became evident that the sense centers (lobi optici and lobi olfactorii) are dependent on the degree of development of the corresponding sense organs, while the higher association centers are independent in this respect. The size of the latter is correlated with the degree of biological complexity of the ant species, the primitive and degraded species having inferior association organs, while the higher genera, such as *Formica*, etc., possess relatively large corpora pedunculata. Of the 3 casts found among the ants, the ♂♂ possess the smallest, the ♀♀ the intermediate sized and the workers the largest corpora pedunculata. In polymorphic species the intermediate sized workers usually show the best developed association organs, while the soldiers of dimorphic species have the corpora pedunculata less well-developed. If these results are compared with the biology of the different species, casts, and undercasts, the conclusion is reached that the size of the corpora pedunculata in Formicidae (36 spp. were investigated) corresponds to the degree of psychological development, or, in other words, that these structures are really a center of the higher psychological functions, a conclusion also supported by histological studies.—*G. Pandazis* (*transl. by P. H. Timberlake*).

11757. **PEACOCK, A. D.** On rearing larvae from eggs dissected out of a saw-fly. *Proc. Roy. Phys. Soc.* [*Edinburgh*] 21(4) : 171-174. 1929.—From a specimen of *Pristiphora pallipes* Lep., which was unable to lay because of defective saws and the absence of saw-guides, 28 eggs were dissected out under water; 16 of these which were pasted on the food-plant (gooseberry), then placed under glass in an incubator at 30°C., died within one day; but from 12 eggs, similarly treated but kept in the laboratory at 13° C., 5 larvae hatched in the normal time of 10 days. The eggs of *P. pallipes* therefore can develop parthenogenetically after artificial removal from the body and possess considerable powers of viability. The egg-pocket is evidently primarily protective, for it is not indispensable for *pallipes* egg nutrition and development. The growth of mould on and around the eggs does not apparently affect development; hence the protective value of the egg chorion must be considerable. Of the 5 larvae hatched only 1 survived; it pupated after a normal life of 20 days; it was, however, smaller than normal and died in the cocoon between 29th June and 23rd July 1928.—*From author's summary.*

11758. **RAU, PHIL.** The silk spun by the larvae of certain social wasps. *Canadian Ent.* 61(10) : 219-221. 1929.—The larva of *Vespa maculata* spins a cocoon, a cell lining, and a lid to its cell. The larva of *Polistes annularis* and of *P. pallipes* spins the lid to the cell and, when the cell is too small, adds several rings of silk. Some cells of *P. annularis* are found lined with silk. Methods of nest building of *Polistes* and those of *Vespa* are compared and found analogous; and a convergent evolution for the 2 genera is suggested.—*M. C. Mansuy.*

11759. **RAU, PHIL.** The habitat and dissemination of four species of Polistes wasps. *Ecology* 10(2) : 191-200. 4 fig. 1929.—The general statement that *Polistes* spp. build in sheds, out-buildings, and overhanging rocks, does not suffice. The conditions probably are that each of the 4 spp. uses a distinct site for its nests; *P. annularis* in trees, *P. variatus* mostly close to the earth, *P. pallipes* in buildings, and *P. rubiginosis*, in hollow trees or in dark recesses. When the 4 species occupy 1 area, a division of nesting sites occurs so that one species may not interfere with the other. If the habitat were the same for all species in a given area, an overcrowded condition and many difficulties would result, together with probable hardships in food-hunting. Then, again, if antipathy exists between the species it may be necessary for the clans to keep far apart. It would be difficult to find a better arrangement under such circumstances than to have one species follow the habit of nesting high up in the branches of the trees, one low down near or in the earth, one building in well lighted sheds, and the other seeking the cover of dark recesses.—*From author's summary and conclusions.*

11760. **SANTSCHI, F.** Trois notes myrmécologiques. *Bull. & Ann. Soc. Ent. Belgique* 70(10/11) : 263-270. 1930.—An annotated list of spp. with key. From Japan: *Crematogaster* (*Acrocoelia*) *brunnea matsumarai* v. iwatensis ♀ (p. 264) and *C.* (*A.*) *b.* st. teranishii ♀ (p. 265). From Cyprus Isl.: *C.* (*A.*) *jehovae* v. cypria ♀ (p. 266) and *Leptothorax bulgaricus* st. cypridis (p. 266). From Africa: first description of ♂ *Bothroponera crassa* st. *crassior* Santschi, ♂ *Pheidole speculifera* Em., ♂ and ♀ *P. s.* st. *ascarus* Em., *Crematogaster* (*Sphaerocrema*) *luctans* v. sordidoides ♀ (p. 269), Sierra Leone; *Myrmicaria natalensis* v. taeniata ♀ (p. 269), Belgian Congo; *Eugramma* tailori ♀ (p. 269), off Mozambique.

11761. **[SKORIKOV, A. S.]** СКОРИКОВ, А. С. Видовой состав подсем. Myrmosini (Hymenoptera, Mutillidae) в фауне СССР. [A note on the sub-family Myrmosini in the USSR. fauna.] Ежегодник Зоологического Музея Академии Наук СССР. (*Ann. Mus. Zool. Acad. Sci. URSS.*) 30(2) : 245-247. 1929.—A key is given to the 6 spp. of *Myrmosa* Latr., and their distribution is compared. *M.* czerskii (p. 246), southern Ussuri region, Siberia.

11762. **SKRIPTSHINSKY, G. P.** Einige neue Schlupfwespen-Arten aus Russland (Fam. Proctotrupidae et Chalcididae). *Konowia* 8(3) : 321-322. 1929.—*Gryon* dagestanicus (p. 321); *Chalcis* turkestanica (p. 322).—*C. E. Mickel.*

11763. **STRAND, EMBRIK.** Kritische Betrachtungen zu einigen hymenopterologischen "Leistungen" des Herrn P. Blüthgen nebst allgemeinen Bemerkungen über

"Typen," "Spezialisten" etc. *Ent. Zeitschr.* [*Frankfurt a. M.*] 42(24): 324-328. 1929.—Answer to Blüthgen's criticism.

11764. **TELENGA, N. A.** Einige neue Ichneumoniden-Formen. *Zool. Anz.* 83(5/8): 185-189. 1 fig. 1929.—**COTIHERESIARCHES** (p. 185), near *Heresiarches*, type *C.* **meyeri*** ♀ (p. 185), Siberia; *C.* **niger** ♀ (p. 186), S. Russia; *Hoplismenus* setaceus ♀ (p. 187), Siberia; *Amblyteles* ferrugineus ♀ (p. 188), Transbaikalia; *Glypta* caucasica ♀ (p. 188), north Caucasia.

11765. **TRAUTMANN, W.** Beitrag zur Kenntnis der Goldwespen Cyperns. *Konowia* 8(2): 154-158. 1929.—Twenty-four spp. of Chrysididae are recorded from Cyprus, including *Hedychrum* **mavromoustakisi** (p. 157), *Chrysis orantiensis* v. **braunsiana** (p. 154), *C. incisa* v. **cypria** (p. 156), *C. succincta* v. **mavromoustakisi** (p. 156), *Holopyga fervida* v. **cypria** (p. 158).—*C. E. Mickel.*

11766. **WATERSTON, JAMES.** On a chalcidoid parasite bred from a flea larva. *Parasitology* 21(1/2): 103-106. 1 fig. 1929.—This insect was bred from cocoons of *Ceratophyllus wickham*, a flea of the American gray squirrel, now introduced in the vicinity of London. It differs from the genus *Pirene* Hal., in antennal, neutrational, and propodeal characters, and therefore requires the formation of a new genus: Miscogasteridae, Pirenini: **BAIRAMLIA** (p. 103), based on *B.* **fuscipes*** (p. 104), England. Type in Brit. Mus.

11767. **WILKINSON, D. S.** A revision of the Indo-Australian and Ethiopian species of the genus Microgaster (Hym. Bracon.). *Trans. Ent. Soc. London* 77(1): 99-123. 7 fig. 1929.—Key is given to 24, including: *Microgaster* **integra** ♂ (p. 103), Uganda; *M.* **resplendens** ♀ (p. 106), Tasmania; *M.* **morata** (p. 106), Victoria, ♀ parasitic on *Thyridopteryx herrichi*; *M.* **tearae** (p. 107), Victoria, on *Teara tristis*; *M.* **rixosa** (p. 108), N. S. Wales, types in Brit. Mus.; *M.* **apo** (p. 108), Philippine Isls.; type in Zool. Mus., Berlin; *M.* **vulpina** (p. 109) and *M.* **perniciosa** ♀ (p. 112), Victoria; *M.* **turneri*** (p. 113), Cape Province; *M.* **earina*** (p. 115), Nigeria, host probably *Earias biplaga*; *M.* **persimilis*** (p. 118), Uganda; *M.* **austrina** ♀ (p. 119), Cape of Good Hope; *M.* **magnifica** (p. 120), Queensland; last 7 types in Brit. Mus. Except where given, hosts of the new spp. are unknown.

11768. **WOJNOVSKAJA-KRIEGER, T. G.** Einige neue Braconiden-Arten aus Russland. *Konowia* 8(2): 234-235. 2 fig. 1929.—*Baryproctus* **niger** (p. 234); *Phanerotoma* **rjabovi*** (p. 234).—*C. E. Mickel.*

MACROLEPIDOPTERA

J. McDUNNOUGH, *Editor*

(See also in B. A. 6(3): Entries 6190, 7799, 7817, 7833, 8638, 8647, 8659; and in this issue 9190, 9463, 10014, 10915, 10945, 11582, 11864)

11769. **ALDIN, d', BERNIER, BRASCASSAT, CASSAGNO, COUTEAU, DUBORDIEU, FRÉMONT, GOURRIN, HENRIOT, JOLIBERT, De JONGHE, Le CHARLES, De LAJONQUIÈRE, MALRIEU, MEILHAN, MELON, De SANDT, SCHIRBER, et TABUSTEAU.** Catalogue des Lépidoptères de la Gironde par un groupe de Lépidoptéristes Girondins. Deuxième partie des Macrolépidoptères. *Actes Soc. Linnéene Bordeaux.* 79: 5-70. 1927.—A local faunistic list including some 694 spp.

11770. **BENTINCK, G. A.** Espèce nouvelle pour les faunes belge et hollandaise. *Lambillionea* 29(4): 50-52. 1929.—Note on *Anaïtis efformata* Guénée.

11771. **BENTINCK, G. A.** Caradrina (Athetis) selini B. et quadripunctata F. (clavipalpis Sc., Cubicularis Schiff). *Lambillionea* 30(3): 42-43. 1 pl. 1930.—Critical notes, with a plate showing the genitalia of 5 spp. of *Caradrina*.

11772. **BENTINCK, G. A.** Ilema (Lithosia) lutarella L., pallifrons Z. et pygmaeola Dbld. *Lambillionea* 30(3): 43-44. 1 pl. 1930.—The ♂ genitalia of these 3 spp. are described and figured.

11773. **DERENNE, F.** Une question de priorité. *Lambillionea* 28(1): 3-6. 1928.—Concerns *Vanessa urticae* v. *ichnusioides* de Selys. The var. was originally so named and described and should be so listed, not *ichnusoides* as it appears in some catalogs.

11774. **DERENNE, F.** Acidalia (Ptychopoda) robiginata Stgr. *Lambillionea* 28(6): 61-62. 1928.—The author states that the sp. recorded in ibid. 1911, p. 56, is *A. similata* Thnbg. and not *A. robiginata* Stgr., and that the notation in Seitz, vol. IV, p. 132, 1913 that the latter sp. had been recently recorded from Belgium is, therefore, also an error.

11775. **DERENNE, F.** Euxoa (Agrotis) temera Hbn. *Lambillionea* 28(6): 62-66. 1928.—Critical notes, with synonymy.

11776. **DERENNE, F.** Cosymbia Hbn. (Ephyra Dup.) ruficiliaria H. Schaff. *Lambillionea* 28(7): 71-74. 1928.—This sp. has been erroneously recorded from Belgium, having been confused with *C. punctaria* v. *hybridaria* (de Selys). The latter proves to be a synonym of *linearia* Hb.

11777. **DERENNE, F.** Phragmatobia fuliginosa L. var. borealis Stgr. ou ab. subnigra Mill.? *Lambillionea* 29(2): 19. 1929.—Belgian specimens hitherto considered as *P. f.* var. *borealis* Stgr. should be called *P. f.* ab. *subnigra* Mill.

11778. **DERENNE, F.** À propos des Lithosia (Ilema) lutarella L., pallifrons Z. et pygmaeola Dbld. *Lambillionea* 29(7): 86-88. 1929.—*Lithosia pygmaeola* is regarded as specifically distinct from the other 2 spp.

11779. **DERENNE, F.** Pieris brassicae L. ab. fasciata Kiefer et alligata Cabeau. *Lambillionea* 30(1): 12-14. 1930.—*P. b.* ab. *alligata* Cabeau is removed from the synonymy of *P. b.* ab. *fasciata*.

11780. **DERENNE, F.** Addenda au catalogue des Géométrides de Belgique. *Lambillionea* 30(2): 22-23. 1930.—Two spp. of *Lythria* are added (with forms).

11781. **DUFRANE, ABEL.** Variation chez Papilio (S. S.) antimachus Drury. *Lambillionea* 29(12): 138-139. 1929.—*P. antimachus* abs. congolanus ♂, vreuricki ♂, Congo; abs. pupillata ♂, obsoleta ♂ (all p. 138), and lagai ♂, Belgian Congo; ab. virgularia (p. 139). Types in author's coll.

11782. **DUFRANE, ABEL.** Mise au point. *Lambillionea* 30(1): 5-6. 1930.—*Metachrostis perla* ab. grisescens (*M. p.* ab. *grisea* Dufrane, not Vorbrodt) (p. 6); *Bryophila* Treit. (=*Metachrostis* Hb.); Bryophilinae (=Metachrostinae).

11783. **DUFRANE, ABEL.** Nouvelles aberrations de Papilio (Pharmacophagus). *Lambillionea* 30(2): 19-21. 1930.—*Papilio priamus poseidon* abs. **nigropunctata** ♂ and **aureopunctata** ♂ (p. 19), **paradoxa** ♀ (p. 20), New Guinea; *P. helena oblongomaculatus* f. *amaura* ab. **obsoleta** ♀ (p. 20), New Guinea; *P. h. o.* f. *o.* ab. **goezei** ♀ (p. 21), Ceram Is.; *P. v*[*ertumnus*] *v.* abs. **latoplaga** ♀ and **rubropuncta** ♀ (p. 21), French Guiana.

11784. **DUFRANE, ABEL.** À propos de l'ab. plasschaerti Dufrane de Pieris brassicae L. *Lambillionea* 30(3): 40-42. 1930.—Critical notes.

11785. **GRAVES, P. P.** Notes on collecting in Ireland. *Ent. Rec. & Jour. Var.* 42(7/8): 97-102. 1930.—Descriptions of the region, notes on frequency, and list of captures, including *Polyommatus icarus* ssp. *clara* (gen. secunda) f. **postclara** (p. 99), type in author's coll.

11786. **GROSSE, G.** Ein neuer Arctiidenhybrid. [Concl.] *Zeitschr. Österreich. Ent.-Ver.* 12(4): 33-35. 1927.—*Diaphora* hybrid *micheli*, note. A list is given of all previously known *Diaphora* hybrids. [See B. A. 2(3/5): entry 8133.]

11787. **HANNEMANN, E.** Eucosmia undulata L. f. heinrichi f. n. (Lep. Geom.). *Internat. Ent. Zeitschr.* 24(34): 366-367. 1 fig. 1930.—*E. undulata* f. heinrichi*, Germany, type in Heinrich coll.

11788. **HANNEMANN, [E.].** [A lecture on butterflies.] *Internat. Ent. Zeitschr.* 24(37/38): 400-401. 1931.—*Chrysophanus amphidamas marchica* fs. ferephlaeas, radiata, and fulva; *Carsia paludata imbutata* f. brunneofasciata; *Lycaena hylas* f. apicipunctata; *Satyrus alcyone* f. caeca. All from Germany; types in author's coll.

11789. **HAYWARD, KENNETH J.** Description of the larvae of Ceratocampa brisottii, Bsdv. *Ent. Rec. & Jour. Var.* 42(10): 136-137. 1930.

11790. **HEPP, A.** Die Schmetterlingssammlung Pfarrer August Fuchs im Naturhistorischen Museum der Stadt Wiesbaden. [The butterfly collection of A. Fuchs in the Mus. Nat. Hist., Wiesbaden, Germany.] (Concl.) *Ent. Anz.* 10(18): 353. 1930.

11791. **HERING, MARTIN.** Neue und alte Lepidopteren. *Mitteil. Zool. Mus. Berlin* 16(4): 513-522. 2 pl., 2 fig. 1930.—*Charaxes ansorgei** Roth. is considered a race or seasonal form of *C. pollux* Cr.; *Thyrgis*, key to spp.; *T.* tenuifascia* (p. 515) and *T. t.* ssp. daguana ♀* (p. 515), Colombia; *Pericopis* variifasciata ♀* (p. 516), Colombia; *P. marginalis* f. tibesina ♂* (p. 517), Costa Rica; *Isostyla* ampliplaga ♀* (p. 517), Colombia; *Nudaurelia* krucki* (p. 518), with f. brunneonigra (p. 519), Kenya Colony; *Micragone* phantasma* (p. 519), Belgian Congo, type in Congo Mus. Tervueren; *Rhodopsona* decolorata ♂* (p. 520), presumably from India or China; EROTOMANIA (p. 520) (Limacodidae), related to *Andrallochroma* and *Eccopa*, type *E.* schoutedeni ♂* (p. 521), Belgian Congo, type in Congo Mus. Tervueren. Types of new forms in Berlin Mus. unless otherwise stated.

11792. **KREMKY, JERZY.** Kleine lepidopterologische Notizen, II. [With Polish summary.] *Fragmenta Faunistica Mus. Zool. Polonici* 1(6): 143-145. 1930.—Records of *Apamea nictitans, A. lucens,* and *A. paludis* in Poland, Russian Podolia, and Austria. The last is by far the most numerous sp.

11793. **NEUMANN, MAX.** Eine neue Form von Smerinthus ocellata L. *Internat. Ent. Zeitschr.* 24(22): 248. 1930.—*S. o.* form flavescens, near Berlin, type in author's coll.

11794. **PROUT, LOUIS B.** A revision of the Indo-Australian Cleora of the alienaria group. *Bull. Hill Mus. [London]* 3(3): 179-222. 3 pl. 1929.—For this group the subgeneric name of *Chogada* (possibly a synonym of the African *Hypopalpis* Guenée) is used. Typical *Cleora* is redescribed. The group is revised with synonymy, original references, key to spp., distribution, with races of several spp., ♂ genitalic figures of practically all spp., and notes. The following are new: *Cleora illustraria* ssp. crina (p. 199), New Ireland; *C.* rhadia* (p. 204), Luzon, Philippines, type in British Mus.; *C. hemiopa* ssp. quirosi (p. 207), New Hebrides, type in coll. Joicey; *C. h.* ssp. ecdees (p. 207), Lifu, Loyalty Is., type at Tring Mus.; *C. concentraria* ssp. inobeda (p. 210), Nias, type at Tring; *C.* cheesmanae* (p. 217), New Hebrides, type in British Mus.—*W. T. M. Forbes.*

11795. **RÖBER, J.** Neue exotische Falter. *Internat. Ent. Zeitschr.* 24(37/38): 389-393. 6 fig. 1931.—*Papilio hahneli* ab. subfasciatus (p. 389), Peru; *Amblypodia* caelestis* (p. 390) and *A.* hyacinthus ♂* (p. 390), New Guinea; *Castnia* atrata ♂* (p. 392), Peru.

11796. **SANDT, de.** Les variations de croceus. *Lambillionea* 30(7): 115-119; (8/9): 123-125; (10): 152-154; (12): 184-188. 1930.—Critical notes.

11797. **SCHAWERDA, KARL.** Mitteilung über das Vorkommen von Leptidia major gen. vern. croatica Grund in Niederösterreich und im Burgenland. [Occurrence of L. major gen. vern. croatica in Lower Austria.] *Verhandl. Zool.-Bot. Ges. Wien* 79(2/4): (105)-(106). 1929(1930).

11798. **SCHAWERDA, KARL.** Meine dritte, vierte und fünfte Lepidopteren-Ausbeute aus dem Hochgebirge Korsikas. *Zeitschr. Österr. Ent.-Vereines* 13(5): 41-49; (12): 111-116. 1928. 14(1): 9-10; (3): 28-30; (6): 57-61. 2 pl. (1 col.). 1929. 15(1): 6-10. 1 pl.; (2): 13-17; (3): 26-30. 1930.—An extensive list including: *Hadena rurea* v. corsa ♀ (p. 43); *Cidaria hydrata* v. clarior ♀ (p. 43); *Argynnis paphia* v. *immaculata* abs. transiens and lilamarginata (p. 44); *Agrotis margaritacea* v. *cyrnea* ab. montedoronis (p. 45); *Hadena adusta* v. *sylvatica* ab. nera (p. 45); *Acidalia honestata* ab. cyanolata (p. 45); *Cidaria frustrata* v. *griseoviridis* ab. olivo-grisea (p. 45); *C. flavicinctata* v. corsaria (p. 46); *C. cyrnea* ab. incudina (p. 46); *Gnophos obscurata* v. *bellieri* ab. vizzavonae (p. 46); *Bryophila perla* v. corsivola (p. 112); *Euxoa haverkampfi* ab. xanthophila ♂ (p. 113); *Rhyacia candelisequa* v. cyrnos ♂ (p. 113); *Anaitis* corsalta (p. 114); *Ptychopoda fuscovenosa* v. corsula (p. 29); *P. aversata remutata* v. griseocorsa (p. 29); *Boarmia lichenaria* v. leukocyrnea (p. 30); *Agrotis saucia* v. tenebricorsa (p. 57); *A. s.* ab. *nigrocosta* Tutt (=*A. s.* ab. *philippsi* Caspari); *Gnophos bellieri* ab. doronis (p. 58); *G.* corsica (*G. variegata c.* Obth.) (p. 59); *G. c.* ab. prouti (p. 59); *Coscinia bifasciata* abs. fortestrigata, paucisignata, and transversata (p. 60); *Cnephasia* joannisi* (p. 60) and ab. evisa (p. 61); *Epagoge montedorea* abs. straminea and pouzatella (p. 61); *Agrotis tritici* v. *falleri* ab. vinosa ♂ (p. 9); *A. corticea* v. *corsa* abs. pallida ♂ and obscura (p. 9); *A. margaritaea* v. *cyrnaea* ab. vixsignata ♂ (p. 10); *Caradrina selinoides* ab. pallens (p. 10); *Gnophos onustaria* abs. tangens and illineata (p. 10); *G. corsica* ab. corsalba ♀ (p. 10); *Cledeobia angustalis* ab. aurantialis (p. 27); *Agrotis crassa* ab. atrata (p. 29). *Eupithecia vulgata* v. *montium, Leucania scirpi* ab. *serratilinea, Hemerophila abruptaria* ab. *theobromina, Agrotis simulans, A. conspicua, Apamea dumerilii, Sesamia nonagrioides,* and *Platyedra vilella* are new to Corsica. A list of spp. known from Corsica is included.

11799. **SCHAWERDA, KARL.** Neue Lepidopteren aus Aragonien. *Zeitschr. Österr. Ent.-Vereines* 13(11): 102-106. 1928.—*Erebia zapateri* ab. punctifera (p. 102); *Macrothylacia digramma* ssp. *curvifascia* (Rothschild) (=*M. rubi* v. *korbi* ab. *bistrigata* Bubacek); *Taragama repanda* ab. roseoclara (p. 103); *Agrotis constanti* abs. rosescens and pallida (p. 103); *A. subdistinguenda* abs. diluta and obscura (p. 103); *Dianthoecia xanthocyanea* v. consparcatoides (p. 103); *Caradrina bermeja* ab. clara (p. 104); *Naenia typica* v. claricolor; *Episema trimacula* ab. elvira (p. 105); *Euclidia glyphica* v. aurantiaca (p. 105), type in author's coll.; *Ortholitha alfacaria albarracina* ab. inondula (p. 105); *Enconista miniosaria* abs. cretacea, grisea, rosescens, and obscura (p. 106).

11800. **SEITZ, ADALBERT.** Die Gross-Schmetterlinge der Erde. *Fauna Africana [Lief. 100-106.]* 14: 569-599. 8 col. pl. Alfred Kernan: Stuttgart, 1930.—Contains index to the plate-vol. (p. V-VII) and conclusion of the index to genera and spp. listed in the now completed vol. 14 of Fauna Africana.

11801. **SEITZ, ADALBERT.** Die Gross-Schmetterlinge der Erde. *Fauna Palaearctica (Suppl.) [Lief. 9-10; 14-20]* 1: 121-296. 4 pl. Alfred Kernan: Stuttgart, 1930-1931.—CHR. BOLLOW (p. 121-126). Conclusion of index to the spp. of the Palaearctic Pieridae. A. SEITZ (p. 127) treats the genera *Danais* Latr. and *Euploea* F., with index to the Palaearctic Danaidae listed with their original descriptions in supplement vol. 1. Of Satyridae, A. SEITZ (p. 129-132) lists *Mandarinia* Leech, *Mycalesis* Hbn., *Lethe* Hbn., *Zophoessa* Dbl., *Melanitis* F., *Neope* Btlr., *Ypthima* Hbn., and *Argestina* Ril. M. GAEDE (p. 131) treats *Callerebia,* including *C.* perocellata (*C. polyphemus* Leech, not Oberth.) (p. 131). H. v. d. GOLTZ (p. 132-152) treats *Erebia* including: *E. kefersteini* ab. effusa (p. 135); *E. haberhaueri* fs. hilaris and tunkuna (p. 136), Sayan Mts.; *E. maurisius* f. lederi* (p. 136), Central Altai; *E. m.* form sajana (p. 136), W. Sayan; *E. turanica* ab. reducta* (p. 137); *E. manto** ab. ligata* (p. 137); *E. m.* ab. rubroligata* (p. 138), Swiss and Bavarian Alps; *E. ceto* ab. extincta ♀ (p. 138), Switzerland, type apparently

in Senckenberg Mus.; *E. stygne* f. **thuringiaca** (p. 140), Thuringian forest, Germany; *E. gorge* ab. **semicaeca** (p. 144), "Pirin" Mts.; *E. aethiops* fs. **uralensis** (p. 146), Ural, and **altaica** (p. 146), Altai; *E. curyale* f. **pyraenaeicola*** (p. 147), E. Pyrenees; *E. e.* var. **minima*** (p. 148) and *E. ligea** f. **altaica** (p. 149), Altai; *E. rossii** abs. **nigra** ♂ and **pallida** (p. 150), Sayan Mts.; it is pointed out that *E. dzhelindae* Shelj. is a local race of *E. eroerda* and not a separate sp.; *E. afer* f. **transcaspica** (p. 152), Transcaspia. M. GAEDE (p. 153-179) treats 8 genera: *Melanargia*, including *M. galathea* **flavina** (*M. g. flava* Fritsch preocc.) (p. 153); *Oeneis; Satyrus*, with *S. dryas* **totacaeca** (*S. d. caeca* Osth. preocc.) (p. 168); *Pararge; Aphantopus; Epinephele; Coenonympha;* and *Triphysa*. Pp. 180-182 contain supplement and corrections to the Palaearctic Satyridae, followed by an index to spp. listed with original descriptions in supplement vol. 1. Of Nymphalidae, CHR. BOLLOW (p. 191-196) treats the subfamily Nymphalinae, including 5 genera. M. GAEDE (p. 196-228) treats the subfamilies Limenitinae, Euthaliinae, and Vanessinae; a short supplement to the Palaearctic Nymphalidae concludes the list, followed by index (p. 228-236) to spp. listed, with original descriptions, in supplement vol. 1. The family Erycinidae is treated by M. GAEDE (p. 237-238), containing *Polycaena* **helcha** (p. 237) and *Dodona maculose* f. **kansuensis** (p. 238), Kansu. Of Lycaenidae, M. GAEDE (p. 239-250) treats 14 genera including *Thecla ilicis* f. *esculi* Hbn. (=*T. i.* form *alineata* Vrty.); *T. i.* form *fountainei** Aign. (=*T. i.* form *powelli* Oberth.). CHR. BOLLOW (p. 250-296) treats the genera *Virachola; Polyommatus; Tarucus; Zizera; Chilades; Everes,* including *E. ion* ssp. **cellariusi** (p. 254), Kansu; *Lycaena,* with *L. sephyrus* ssp. **trappi** (*L. s.* ssp. *lycidas* Trapp, nec Meigen) (p. 263), *L. eumedon* **stauderi** (*L. e. meridionalis* Stauder) (p. 271), *L. icarus* ab. *semipersica* Tutt (=*L. i.* ab. *paucipuncta* Courv.), *L. i.* ab. *subtusradiata* Oberth. (=*L. i.* ab. *striata* Gillm.), and *L. lycormas* **sumpantingi** (p. 287), Szechwan; and *Cyaniris;* and begins the genus *Taraca*.

11802. TAMS, W. H. New African Lasiocampidae. *Ann. and Mag. Nat. Hist.* 7(37): 1-17. 2 pl. 1931.—*Opisthodontia* **spodopasta*** (p. 2), Gold Coast; *Pseudolyra* **megista*** (p. 3) and *P.* **parva** ♂* (p. 4), Uganda; *Streblote* **finitorum** ♂* (p. 4) and *S.* **collenettei** ♂* (p. 5), Brit. Somaliland; *S.* **dysimata** ♀* (p. 5), Sudan; *S.* **callizona** ♀* (p. 6), Kenya Colony; *Bombycopsis* **hyatti** ♀* (p. 7), Somaliland; *B.* **lepta** ♀* (p. 7), Kenya Colony; *Leipoxais* **typodes** ♀* (p. 8), Uganda; *L.* **dolichoprygma** ♂* (p. 9), Belgian Congo; *Odontocheilopteryx* **ungemachi** ♂* (p. 10) and *O.* **eothina** ♂* (p. 11), Abyssinia, types in Ungemach coll.; *Chilena* **scotti** ♂* (p. 12), Abyssinia; *C.* **cardinalli*** (p. 13), Gold Coast; *Chrysopsyche* **pyrodes** ♂* (p. 13) and *Lechriolepis* **nephopyropa** ♂* (p. 14), Rhodesia; *L.* **cryptognoma** ♂* (p. 15), central Africa; *Trabala* **prasinosphena*** (p. 15), Belgian Congo. Types in Brit. Mus. unless otherwise specified.

11803. TAYLOR, JOHN SNEYD. Notes on some south African Lepidoptera. *Ent. Rec. & Jour. Var.* 42 (9): 122-123. 1930.—Descriptions of larvae of spp. of Noctuidae (6), Geometridae (1), Saturniidae (1), and Lycaenidae (1), with their food plants.

11804. TURNER, HY. J. British Noctuae and their varieties. [Continuation.] *Ent. Rec. & Jour. Var.* 42 (7/8 suppl.): (145)-(152); (10 suppl.): (153)-(156). 1930.—Critical, comparative, and synonymic notes and a few new descriptions. *Nonagria dissoluta* ab. **flavia** (p. (147)); *N. sparganii* abs. **impunctata** and **clara** (p. (155)); Wightman has described the following: *N. s.* abs. **lutea, rosea** (p. (155)), **rufa, nigrostriata, roseoradiata,** and **deleta** (p. (156)).

11805. VERITY, ROGER. According to the rules of nomenclature the name of Argynnis adippe is of Rottemburg (nec L.), and that of Melitaea dictynna, Esp., must be replaced by diamina, Lang. *Ent. Rec. & Jour. Var.* 42 (11): 149-152. 1930.

11806. WALSCHE, JULES de, et al. À propos de la répartition de certains lépidoptères belges. *Lambillionea* 29 (3): 38-41; (4): 57-58. 1929.—Notes on the distribution and status of *Aporia crataegi, Apatura iris, A. ilia,* and *Chrysophanus dorilis* in Belgium.

11807. WARNECKE, G. Sideridis (Leucania) velutina Esp. no. subsp. enervata Warn. (Lep. Noct.). *Mitteil. Deutschen Ent. Ges.* 1(8): 120-121. 1930.—*S. v.* ssp. enervata, Vladivostok, type in Zool. Mus. Hamburg.

11808. WOLFF, NIELS L. On individual variation of a structural character in the genus Oporinia Hb. (Lep. Geom.) *Ent. Meddel* [*Copenhagen*] 16(7): 391-397. 1929.—States, with graphs, the result of examining 259 Danish specimens of *Oporinia* ♂♂ (*O. dilutata* Bkh. (39 specimens), *O. christyi* Prt. (143), and *O. autumnata* Bkh. (57)), studying the individual variation of the distance of the octavals.—*N. L. Wolff.*

11809. WORM-HANSEN, J. G. The lepidopterous fauna of San Cataldo (southern Italy). Notes from a collecting trip in the late-summer 1928. *Ent. Meddel.* [*Copenhagen*] 16(8): 425-432. 1930.—A list of 110 spp. with notes on occurrence and frequency. The total of specimens of all insect orders collected was 3000. Moths proved to be chance catches, as treacle with added acetic ether, used in Denmark with great results, had no attraction for the moths of this part of Italy.

MICROLEPIDOPTERA

CARL HEINRICH, *Editor*

(See also in B. A. 6(3): Entries 7771, 7773, 7775, 7799, 7811, 8431, 8638, 8659, 8812; and in this issue 10889, 10896, 10901, 10911, 10917, 10923, 10929, 10933, 10946, 11582, 11791, 11795, 11798)

11810. BORTHWICK, ANN V. Notes on a tineid moth (Hyponomeuta evonymellus Linn.) and its occurrence in Midlothian. *Scottish Nat.* 1931(191): 149-152. 1931.—This sp. was attacking trees of *Prunus padus*.

11811. BOX, HAROLD E. The crambine genera Diatraea and Xanthopherne (Lep., Pyral.). *Bull. Ent. Res.* [*London*] 22(1): 1-50. Map, 5 pl., 4 fig. 1931.—A table shows the distribution by countries of the 48 American spp. of *Diatraea*. *Diatraea* Guilding (=*Iesta* Dyar, *Trinidadia* Dyar & Heinrich) (p. 11), emended description and key to spp.; *D.* **argentina*** (p. 18), Argentina, type in British Mus.; *D. morobe*, first description of ♂; *D. crambidoides** Grote (=*D. zeacolella* Dyar, *D. tripsacicola* Dyar), removed from synonymy of *D. saccharalis; D. saccharalis** (F.) (=*D. sacchari* Guild., *D. incomparella* Dyar & Heinrich); *D. indigenella**, ♂ described; *D.* **brunnescens** ♀* (p. 29), Venezuela; *D.* **incertella*** ♂ (p. 30), Brazil; *D. continens**, first descr. of ♂; *D.* **luteella*** (p. 32), Ecuador; *D.* **suffusella*** ♀ (p. 33), French Guiana; *D.* **albicrinella*** (p. 34), Brit. Guiana, Brazil (type), Peru, and Ecuador; *D.* **amazonica*** (p. 36), Brazil (type) and Argentina; *D.* **rufescens** ♂* (p. 37), Bolivia; *D.* **entreriana*** (p. 39), Argentina; *D. impersonatella* (Walk.) (=*D. moorella* Dyar & Hein.), removed from synonymy of *D. lineolata; D.* **flavipennella*** (p. 42), Brazil, type in Brit. Mus.; *D. lineolata* (Walk.) (=*Chilo culmicolellus* Zeller, *C. neuricellus* Zeller) [much of the sugar cane literature on this sp. is incorrect, records from the United States referring to *D. grandiosella,* and from Trinidad and Brit. Guiana to *D. impersonatella*]; *Xanthopherne* D. & H., key to spp.; *X.* **heinrichi** ♂* (p. 48), Peru, type in U. S. Nation. Mus.; *X.* **bimaculata*** (p. 49), Peru (type) and Venezuela; *X.* **endothermalis*** (*Diatraea e.* Hamps.). Types, unless otherwise stated, in Tring Mus. *Chilo comparellus* Felder & Rogen. is not a synonym of

Diatraea saccharalis, nor does it belong to *Diatraea*. The genitalia of 31 spp. are illustrated. Full synonymical notes are given for all spp.

11812. HEDDERGOTT. Aufsuchen von Sesienraupen. *Internat. Ent. Zeitschr.* 25(2): 21-24. 1931.—Notes on the larvae of *Trochilium apiformis, T. crabroniformis, Sciapteron tabaniformis, Sesia spheciformis, S. tipuliformis, S. conopiformis, S. vespiformis, S. myopaeformis, S. culiciformis, S. formicaeformis, S. ichneumoniformis, S. empiformis*, and *Zeuzera pyrina*.

11813. HERING, MARTIN. Ein neuer Parietaria-Minierer, Cosmopteryx parietariae sp. n. (Lep.). *Mitteil. Deutsch. Ent. Ges.* 2(5): 67-70. 3 fig. 1931.—*Cosmopteryx* parietariae* (p. 68), a leaf miner in *Parietaria ramiflora*, Italy. It is compared with *C. turbidella**.

11814. McDUNNOUGH, J. A new Argyroploce species (Eucosmidae, Lepid.). *Canadian Ent.* 63(7): 150-152. 3 fig. 1931.—*A.* trinitana* (p. 151), Ontario (type in Canadian Nat. Coll., Ottawa), Manitoba, Quebec, and Saskatchewan; bred from *Cypripedium pubescens*.

11815. MEYRICK, EDWARD. Exotic Microlepidoptera. 3(18): 545-576. Published by the author: Thornhanger, Marlborough, Wilts, England, 1930. Pr. 3 s.—Cosmopterygidae. *Labdia* semiramis ♀ (p. 545), Solomon Is., on *Cocos nucifera; L.* niphoxantha ♀ (p. 545), Central Provinces, India, from *Litsea polyantha; L.* orthritis ♂ (p. 545), Fiji Is., type in Brit. Mus.; *Pyroderces stagmatophora*, in Uganda, on *Androphogon sorghum; P.* haemodryas ♀ (p. 546), Malay Peninsula, from *Nipa fruticans; Stagmatophora* niphochrysa ♂ (p. 546), Texas; *Limnoecia* xanthotyla ♂ (p. 546), Solomon Is.; MELANOZESTIS (p. 547), between *Leptozestis* and *Ascalenia*, for *M.* heterodesma ♀ (p. 547), Natal, type in Brit. Mus.; *Mompha trithalama* Meyr., from *Clidemia pustulata* (p. 547); *Batrachedra knabi* Wals. (=*B. enormis* Meyr.). Tineidae: *Tinea* absolutrix ♀ (p. 547), Peru; *T.* isocharis (p. 547), New Guinea; CYNOMASTIX (p. 548), allied to *Mastigostoma* and *Cyathaula*, for *C.* rhothodoxa ♀ (p. 548), New Caledonia, type in Brit. Mus.; *Hypophrictis* spiloglypta ♂ (p. 548), Siam, type in Brit. Mus.; ENDOTHETIS (p. 549), allied to *Tanymita*, for *E.* anomogramma ♀ (p. 549), New Britain; *Themeliotis* projectrix ♂ (p. 549), New Britain; *Melasina* lavata ♂ (p. 550), *M.* zalomorpha ♂ (p. 550), and *M.* melicrana ♂ (p. 550), Sudan; *M.* isopoca (p. 551), Belgian Congo; *M.* obtrectans (p. 551), Kanara, [S. India]; *M.* vorticosa (p. 551), Bombay; *M.* spaniocctenis ♂ (p. 552), Uganda, type in Brit. Mus.; *Acrolophus* empedocles ♂ (p. 552), Brazil; *Tinea allutella* Rebel (=[*T.*] *utcrella* Wals.=[*T.*] *pachyspila* Meyr.); *Hapsifera* platyloxa ♂ (p. 553) and *H.* incrustata (p. 553), Uganda, type of latter in Brit. Mus.; XERANTICA (p. 553), between *Hapsifera* and *Drosica*, for *X.* tephroclysta ♂ (p. 553), Uganda, type in Brit. Mus.; PHILAGRAULA (p. 554), for *P.* punica ♀ (p. 554), Sudan, bred from decaying stem of date palm; *Narycia* crocodilitis (p. 554), Uganda. Xyloryctidae: *Odites* malivora ♀ (p. 555), Manchuria, bred from larva rolling leaf of *Pyrus malus; O.* balanospila ♂ (p. 555), Sierra Leone, type in Brit. Mus.; *Asapharcha* crateropa ♂ (p. 555), Portuguese E. Africa; *A.* nephelomicta ♀ (p. 555), New Mexico; *Antaeotricha* cyprodeta (p. 556) and *A.* serarcha ♀ (p. 556), Brazil; *A.* sortifera ♀ (p. 557), Bolivia; *Stenoma* ogmolopha ♂ (p. 557) and *S.* crypsithias ♀ (p. 558), Brazil; *S.* sciogama ♂ (p. 558), Bahia, bred from larvae feeding on leaves of *Anona squamosa*, type in Brit. Mus.; *S.* hyacinthitis ♀ (p. 559), British Guiana, type in Brit. Mus.; *S.* ulosema ♂ (p. 559) and *S.* macraulax ♀ (p. 559), Brazil; BRYONYMPHA (p. 560), probably allied to *Agriophara* and *Ptilogenes*, for *B.* silvana ♂ (p. 560), Comoro Is. [Mosambique Chan.]; *Agriophara* muscicolor ♂ (p. 560), Brit. New Guinea, type in Berlin Ent. Mus. Scythridae: *Scythris* hydronoma ♀ (p. 561), Sudan; *S.* delodelta ♂ (p. 561), Natal, type in Brit. Mus. Coleophoridae: *Coleophora* castalia ♂ (p. 561) and *C.* echyropis ♂ (p. 562), Kashmir. Hyponomeutidae: *Zelleria* semitincta ♂ (p. 562), Texas; *Pronomeuta sarcopis* (p. 562), bred from larvae skeletonizing leaves of *Hydnocarpus wrightiana;* STICHOTACTIS (p. 562), probably allied to *Homadaula*, for *S.* calamitosa (p. 563), Sudan, bred from *Acacia nilotica* and *A. arabica; Ethmia* hamaxastra ♀ (p. 563), Portuguese E. Africa; *Prodidactis*, transferred from the Tortricidae and characterization as a hyponomeutid given. Pterophoridae: *Trichoptilus* bidens ♂ (p. 564), Assam; *Oxyptilus* scutifer ♀ (p. 564), Ecuador; *O.* indentatus (p. 564), Texas and New Mexico; *O.* intercisus (p. 565), Croatia, type in Berlin Ent. Mus.; *Deuterocopus* deltoptilus ♂ (p. 565), Uganda, type in Brit. Mus.; *Platyptilia* niphadarcha ♂ (p. 566), Uganda, type in Brit. Mus.; *P.* saeva ♀ (p. 566), Peru (9000 ft.); *P.* macrornis ♀ (p. 567), Turkestan; *Alucita* endophaea ♀ (p. 567), Portuguese E. Africa; *A.* dryogramma (p. 567), Croatia, type in Berlin Ent. Mus.; *Adaina* subflavescens (p. 568), Sumatra, bred from flowers of *Pluchea indica; A.* excreta ♂ (p. 568), Peru (9000 ft.); *Pterophorus* excors ♂ (p. 568), Askold Is.; E. Siberia; *P.* jason ♂ (p. 568), Brazil; *P.* nauarches ♂ (p. 569) and *P.* chionophanes ♂ (p. 569), Peru (9000 ft.); *P.* zetes ♀ (p. 569), Bahia; *P.* calais ♂ (p. 570), Pernambuco; *Stenoptilia* megalochra (p. 570), Bulgaria; *S.* philocremna (p. 570), Texas and New Mexico (at 7000 ft.). Adelidae: *Nemotois* photodoxa ♂ (p. 571), New Guinea; *N.* cyanochrysa ♂ (p. 571), New Ireland; *N.* hippophylax ♀ (p. 572), British New Guinea; *Adela* arabarcha ♂ (p. 572), Tunis; *Ceromitia* aphroneura ♂ (p. 572), Portuguese E. Africa. Oecophoridae: STASIXENA (p. 573), for *S.* subagrestis ♂ (p. 573), Brazil; *Gonada* flavidorsis ♂ (p. 573), Brazil; *Borkhausenia* chalcocrates ♂ (p. 574), Croatia; *Eochrois* erebocrossa ♀ (p. 574), Queensland; *Elaphrerga* eucentrota (p. 574), Andaman Is.; *Filinota* vociferans ♀ (p. 574), *Hypercallia* autocrena ♂ (p. 575), *H.* halobapta ♂ (p. 575), and *H.* citroclista ♀ (p. 576), Brazil; *H.* heliomima ♂ (p. 576), Colombia.

11816. STERNEK, JAKOB. Venilia macularia ab. krombholzi nov. *Internat. Ent. Zeitschr.* 25(4): 37-38. 1 fig. 1931.—From Bohemia.

11817. TABATA, IKUO. Some studies on morphology and ecology of Cnaphalocrocis medinalis Guén. [In Japanese.] *Ann. Agric. Exp. Sta. Govt.-Gen. Chosen* 5(2): 127-134. 1930.

NEUROPTEROIDS

F. M. CARPENTER, *Editor*

(See also in this issue Entries 10945, 10946, 11247, 11590)

11818. ANDER, KJELL. Trollsländor-Odonata. 13. In: Insektfaunan inom Abisko Nationalpark. III. Studies under the leadership of Yngve Sjöstedt. *K. Svenska Vetenskapsakad. Skrifter i Naturskyddsärenden* 18. 60-63. 1931.—A list of 6 spp., with locality and distributional notes.

11819. BANKS, NATHAN. Trichoptera from Cape Breton, Nova Scotia. *Bull. Brooklyn Ent. Soc.* 25(3): 127-132. 1 pl. 1930.—A list of 4 Phryganeidae, 16 Limnephilidae, 3 Sericostomatidae, 1 Leptoceridae, 3 Rhyacophilidae, and 4 Hydropsychidae; including the following. Sericostomatidae: ARCADOPSYCHE (p. 129), near *Crunoecia*, based on *A.* prominens* (p. 129); Rhyacophilidae, *Rhyacophila* fairchildi* (p. 130); Hydropsychidae, *Plectrocnemia* aureola* (p. 130); *P.* albipuncta* (p. 131). Types in Mus. Comp. Zool.

11820. BANKS, NATHAN. Some oriental neuropteroid insects. *Psyche* [*Boston*] 38(1): 56-70. 1 pl. 1931.—Corrodentia, Psocidae: *Hageniella* pusilla (p. 56), *Tagalopsocus* hyalinus (p. 58), and *Ectopsocus aethiops* v.

bakeri* (p. 58), Philippines. Neuroptera, Myrmeleonidae: *Stenares* frazeri ♀ (p. 58) and *Nesoleon* perpunctatus (p. 59), India; EOPHANES (p. 60), near *Paraglenurus*, type *E.* formosa* (p. 61), Luzon; *Formicaleo schladeri* Van der Weele is provisionally referred to *Eophanes; Syngenes* palpalis (p. 62), Madras; *Madrasta handlirschi**, redescribed from Luzon material. Ascalaphidae: *Suhpalacsa* reducta (p. 63), Luzon, Samar, and Negros. Chrysopidae: *Chrysopa* obliquata (p. 64), Luzon; *Spilosmylus ceylonensis,* first descr. of ♀. Trichoptera, Sericostomatidae: *Goera* tagalica* ♀ (p. 66), *Gocrinella* minor* (p. 67) and *Anisocentropus* bellus* (p. 67), Luzon. Hydropsychidae: *Macronema* caliptera* (p. 68), Luzon; *Dipseudopsis* spectabilis* (p. 69), Borneo. Rhyacophilidae: *Rhyacophila* carletoni* (p. 69), north India. Types in Mus. Comp. Zool.

11821. **BENGTSSON, SIMON.** Dagsländor-Ephemeroptera. 11; Sjösländor-Plecoptera. 12. In: Insektfaunan inom Abisko Nationalpark. III. Studies under the leadership of Yngve Sjöstedt. *K. Svenska Vetenskapsakad. Skrifter i Naturskyddsärenden* 18. 56-60. 1931. —A list of 16 Ephemeroptera and 15 Plecoptera, with brief notes on locality and distribution.

11822. **CARPENTER, FRANK M.** The biology of the Mecoptera. *Psyche* 38(1): 41-55. 1 fig. 1931.—The writer reviews the history of the knowledge of these insects and discusses their mating and feeding habits, and metamorphosis, emphasizing the fact that relatively little is known of their biology.

11823. **CRAMPTON, G. C.** The genitalia and terminal structures of the male of the archaic mecopteron, Notiothauma reedi, compared with related Holometabola from the standpoint of phylogeny. *Psyche* 38(1): 1-21. 4 pl. 1931.—*Panorpa* hirsuta* (p. 10), India, type in Mus. Comp. Zool. The abdominal structures of *Notiothauma reedi** indicate that this remarkable insect is a remnant of the ancestral Mecoptera and is the nearest living representative of the ancestors of the Panorpidae. The family Notiothaumidae may be placed before the Panorpodidae and Panorpidae. The genitalia of numerous other Mecoptera are figured.

11824. **DESPAX, R.** Description sommaire d'un sous-genre nouveau et de deux espèces nouvelles du genre Leuctra Steph. [Plecoptera]. *Bull. Soc. Ent. France* 1929(19): 298-301. 1929.—PACHYLEUCTRA (p. 298) erected as a new subg. for *Leuctra* (*P.*) montana (p. 299) (type), Pyrenees, Haute-Garonne, and *L.* (*P.*) ribauti (p. 301), Saint-Béat, Haute-Garonne.—*S. B. Fracker.*

11825. **FORSSLUND, KARL-HERMAN.** Nattsländor-Trichoptera. 10. In: Insektfaunan inom Abisko Nationalpark. III. Studies under the leadership of Yngve Sjöstedt. *K. Svenska Vetenskapsakad. Skrifter i Naturskyddsärenden* 18. 46-55. 1931.—A list of the spp. (44) hitherto known from the Abisko region, with distributional notes.

11826. **LAIDLAW, F. F.** Remarks on some Odonata (dragonflies) from Mangalum Island, North-west Borneo. *Bull. Raffles Mus.* 5. [90]-[92]. 1931.—The odonate fauna indicates that this island once formed part of Borneo. An annotated list of 10 spp. is given. *Lestes praemorsa,* new to the Bornean list.

11827. **LESTAGE, J. A.** Études sur les Mégaloptères. VI. Les Austrosialis de la Tasmanie. *Bull. & Ann. Soc. Ent. Belgique* 70(3/4): 107-113. 1930.—A comparative study showing that the fundamental venation, as indicated by Tillyard in his publication on Megaloptera, remains constant; the cross-venation however is subject to great changes which are noticeable to an equal degree in the archaic members of the family Sialidae of the Australian fauna, as well as in the more recently evolved species of the present fauna. The number and importance of these variations are not specific, but are individual. —*C. Zeimet.*

11828. **LIEFTINCK, M. A.** A revision of the genus Epophthalmia Burm. (Odon., Corduliinae), with notes on habits and larvae. *Treubia* 13(1): 21-80. 1 col. pl., 29 fig. 1931.—*Epophthalmia* Burmeister (=*Azuma* Needham not Jordan & Snyder); descriptive key to ♂♂ and ♀♀; the genitalia of each sex are illustrated, *E. elegans* ♂* ♀*, mature larva*, a subsp.? is illustrated in color; *E. frontalis* ♂* in color, and genitalia; *E. vittata vittata* ♂* ♀*, mature larva*; *E. v. cyanocephala* ♂*; *E. v.* sundana (p. 61), ♂* in color, egg*, first larva*, Java, type in Buitenzorg Mus.; *E. australis* ♂* in color; *E. vittigera* ♂* ♀*, mature larva*.

11829. **LUCAS, W. J.** Notes on British Paraneuroptera in 1930. *Entomologist* [*London*] 64(819): 175-179. 1931.—Records of collecting Aeschnidae, Libellulidae, Calopterygidae, Lestidae, and Agrionidae.

11830. **McDUNNOUGH, J.** The bicolor group of the genus Ephemerella with particular reference to the nymphal stages (Ephemeroptera). *Canadian Ent.* 63(2): 30-42. 4 pl.; (3): 61-68. 1931.—*Ephemerella,* key to nymphs and species in *E. bicolor* group; all nymphs are fully described and figured; *E. lutulenta** Clemens (=*E. lineata* Clemens); *E. temporalis** McD., 1st description of nymph; *E.* prudentalis* (p. 40), *E.* minimella* ♂ (p. 63) and *E.* aestiva* (p. 64), Quebec, types in Canadian Natl. Coll. The ♂ genitalia and ♀ subanal plate are illustrated in several spp.

11832. **McDUNNOUGH, J.** The genus Isonychia (Ephemeroptera). *Canadian Ent.* 63(7): 157-163. 6 fig. 1931.—*Isonychia,* key to spp.; *I. arida**, *I.* georgiae ♂* (p. 159), Georgia; *I. sicca**; *I. s.* var. *manca**; *I. s.* var. campestris* (p. 161), Alberta; *I. bicolor**; *I.* rufa* (p. 162), Iowa. Types in Canadian Nat. Coll., Ottawa.

11833. **MORSE, MIRIAM.** The external morphology of Chrysopa perla L. (Neuroptera: Chrysopidae). *Jour. New York Ent. Soc.* 39(1): 1-42. 4 pl. 1931.—A critical study of the sclerites of the adult, with a bibliography on insect morphology of 48 references.

11834. **MORTON, KENNETH J.** Hemerobius perelegans Stephens: A good species. *Entomologist* [*London*] 64(820): 197-201. 1 pl., 3 fig. 1931.—*Hemerobius p.** is removed from the synonymy of *H. subnebulosus.* It is compared with *H. humuli* and *H. orotypus.*

11835. **MOSELY, MARTIN E.** The genus Diplectronella Ulmer (Trichoptera). *Ann. and Mag. Nat. Hist.* 8(44): 195-205. 4 pl., 5 fig. 1931.—*Diplectronella,* redescribed; *D. taprobanes**, wings* and ♂ genitalia*; *D.* indica* (p. 199), India; *D.* afra ♂* (p. 202), Uganda. Types in Brit. Museum.

11836. **MOSELY, MARTIN E.** Apatania arctica Bohem, ♂. *Entomologist* [*London*] 64(813): 34. 1931.—*Apatania palméni* J. Sahlb. may be the ♂ of *A. arctica.*

11837. **MOSELY, MARTIN E.** Trichoptera and Ephemeroptera of British Guiana, with special reference to the Oxford University Expedition to British Guiana, 1929. *Entomologist* [*London*] 64(819): 169-170. 1931. —A list of 21 spp. of Trichoptera and 5 Ephemeroptera from Brit. Guiana.

11838. **MUSGRAVE, PAUL N.** A coleopterous enemy of Corydalis cornuta L. (Anthicidae: Neur.: Sialididae). *Ent. News* 42(7): 202-203. 1931.—*Anthicus heroicus* infested egg masses of *Corydalis cornuta* on the Potomac River in W. Virginia, usually pupating in cells in the soil beneath the egg masses.

11839. **STEGER, ANNE LOUISE.** Some preliminary notes on the genus Ephemerella. *Psyche* 38(1): 27-35. 1 pl. 1931.—Contains descriptions and illustrations of stages in the life cycle of *Ephemerella cornuta**, *E. dorothea*, *E. rotunda,* and *E. septentrionalis**; all collected at Ithaca, New York.

11840. **TJEDER, BO.** Nätvingar-Neuroptera. 9. In: Insektfaunan inom Abisko Nationalpark. III. Studies under the leadership of Yngve Sjöstedt. *K. Svenska Vetenskapsakad. Skrifter i Naturskyddsärenden* 18. 42-46. 1931.—This paper is based on material belonging mainly to Naturhist. Riksmus., Stockholm, consisting of 36 specimens, representing 7 spp. which are here listed, with notes on locality and distribution.

11841. **TRAVER, JAY R.** The ephemerid genus Baetisca. *Jour. New York Ent. Soc.* 39(1): 45-64. 1 pl. 1931. —*B.* carolina* (p. 52), N. Carolina; *B.* callosa* (p. 57), W. Virginia.

ORTHOPTEROIDEA

A. N. CAUDELL, *Editor*

(See also in this issue Entries 9175, 9182, 10883, 10908, 10910, 11247, 11588)

11842. ANDER, KJELL. Rätvingar-Orthoptera. 14. In: Insektfaunan inom Abisko Nationalpark. III. Studies under the leadership of Yngve Sjöstedt. *K. Svenska Vetenskapsakad. Skrifter i Naturskyddsärenden* 18. pp. 64-69. 1931.—An account of the Orthoptera collected in the Abisko region, represented by 1 cockroach and 2 grasshoppers.

11843. BERLAND, L., et L. CHOPARD. Remarques sur Diponthus cribatus Serville (Orthoptère Acridien), et sur les types de Serville en général. *Bull. Mus. Nation. Hist. Nat. [Paris]* 1(2): 143. 1929.—*Diponthus* cribatus (*Acridium cribratum* Serv.).

11844. CRAMPTON, G. C. The affinities of Grylloblatta indicated by a study of the head and its appendages. *Psyche* 33(3): 78-85. 1 fig. 1926.—The writer believes that *Grylloblatta* is practically a living protorthopteron, very closely related to the common stock from which sprang the Tettigonioid and Grylloid Orthoptera. Outside of the true Orthoptera, the next of kin of the Grylloblattids are the Dermaptera, with the Phasmidae more remotely related. The head capsule of *Grylloblatta* is forficuloid; the maxillary lacinia and galea resemble those of *Gryllotalpa;* the labium is typically orthopteroid; the mandible resembles that of *Gryllotalpa;* the antennae resemble those of *Embia.*

11845. KARNY, H. H. Die Gryllacriden von Neu-Guinea. In: *Nova Guinea, Resultats Exped. Sci. Nouvelle Guinée* 15(4): [1]-[44]. Map, 1 col. pl., 20 fig. E. J. Brill S. A., Leiden, 1930.—Gryllacrinae: GLENOGRYLLACRIS (p. 3) described as a new genus with "*Glenogryllacris pretiosa* n. sp." as type, but on p. 4 is used as a subgenus. *Gryllacris* (*Gl.*) pretiosa ♀* (p. 4); *Gryllacris* griseola ♀* (p. 8); *G.* (*Papuogryllacris*) *ligata*; G.* (*P.*) *dimidiata,* key to 6 subspp., including chalybeata ♀* (p. 12) and signicollis ♂* (p. 14); *G.* (*P.*) *trianguligera** and its subsp. dimidiatipes ♀* (p. 17); *G.* (*P.*) *diluta* v. *huoniana*; G.* (*P.*) piceicollis ♀* (p. 19); *G.* (*P.*) *purarica* spp. brachyura ♀* (p. 22); *G.* (*P.*) parvolaminata ♀* (p. 23); *G.* (*P.*) leeuweni* (p. 26); *G.* (*P.*) *vidua*; G.* (*P.*) circumdata ♀* (p. 30); *G.* heurnii ♀* (p. 32); *G. giulianettii,* first descr. of ♂*; *G. multicolor* v. nigropicta ♀* (p. 37); *G. ebneri*; G. punctipennis*; G. urania**. Henicinae: *Papuaistus pallicrus* descr. of ♀ allotype. Rhaphidophorinae: *Rhaphidophora* alpha ♂* (p. 41), and *R.* beta ♂ (p. 41). Types in Buitenzorg Mus.

11846. RAMME, W. Beiträge zur Kenntnis der palaearktischen Orthopterenfauna (Tettig. et Acrid.). *Mitteil. Zool. Mus. Berlin* 17(1): 165-200. 1 pl., 13 fig. 1931.—Tettigoniidae: *Poecilimon gracilis* is distinguished from *P. schmidti; P. brunneri* Friv. (=*P. berlandi* Uv.); P. poltoratskyi (*Isophya p.* Uv.) (p. 166); *P.* neglectus* (p. 167), Asia Minor; *Isophya* brevicauda* (p. 168), Jugoslavia, type in Berlin Mus.; *I. bivittata* Uv. (=*I. transcaucasica* Ramme); *I. modestior* Br. (=*I. fusconotata* Br.); *Barbitistes serricauda* occurs on *Alnus glutinosa;* notes on *B. ocskayi* and *B. yersini; Ancistrura* nigrovittata (*Barbitistes nigrovittatus* Br., =*B. brunneri* Panč., *Ancistrura truncata* Uv.); METAPLASIA (p. 172), near *Barbitistes* and *Ancistrura,* type *M.* oertzeni* (*B. o.* Br.) (p. 174); *M.* pulchripennis* (*B. p.* Costa) (p. 175); *M.* ornata* ♂ (p. 174), Greece, type in Berlin Mus.; *Leptophyes albovittata,* descriptive note; *Drymadusa* ornatipennis (*Paradrymadusa o.* Ramme); *Pholidoptera* ebneri* (p. 177), Albania; *Platycleis romana* descr. notes; *P. eversmanni* (Kitt.) (=*P. dubia* Uv., *P. falzfeini* Ramme); *Metrioptera coracis** and *M. dofleini* descr. notes; *M.* kuntzeni* (p. 181), Istria; *M. oblongicollis* (Br.) (=*Pholidoptera albanica* Čsiki); *Decticus verrucivorus** is compared briefly with *D. annaelisae*; Psorodonotus fieberi* ssp. *fieberi** is compared with *P. f.* ssp. macedonicus* (p. 184), Macedonia; *P. uvarovi*, P. illyricus* Ebner is removed from *P. fieberi* and raised to species rank. Acrididae: *Stenobothrus* posthumus* (p. 188), Montenegro, type in Berlin Mus.; *Stauroderus* eisentrauti* (p. 190), Austria; *Euchorthippus* angustulus* (p. 191), Balearic Isls., compared with *E. pulvinatus*; Oedipoda fuscocincta* ssp. portugalensis* (p. 193), Portugal; *Pamphagulus* uvarovi ♀* (p. 193), Mauretania, type in Paris Mus.; *P.* vicinus ♀* (p. 195), Tunis, type in Paris Mus.; *Podisma emiliae,* descr. notes; *P. schmidti* ssp. rubripes (p. 197), Rumania; *P. alpina* f. leisleri (p. 197), Austria; *Conophyma fedtschenkoi* ssp. ornatum* (p. 198), South Turkestan, type in Hamburg Mus.

11847. UVAROV, B. P. Notes on the genus Iris, Saussure (Orthoptera, Mantidae). *Ann. and Mag. Nat. Hist.* 8(45): 234-238. 1 pl. 1931.—*Iris* radians ♂* (p. 234), Punjab, type in Imp. Inst. Ent.; *I. oratoria* coeca ♂* (p. 235), Sudan; *I. o.* polystictica (*Mantis p.* Fischer-Waldheim=*Iris tiflisina* Giglio-Tos) (p. 236); a catalogue and key of spp. is given.

11848. WILLEMSE, C. A new species of Aucacris from Chile. (Orthopt., Cyrtacanthacr.) *Mitteil. Deutschen Ent. Ges.* 2(2): 22-24. 1 fig. 1931.—*A.* hebardi ♀* (p. 22), type in Mus. Hamburg.

11849. ZEUNER, FRIEDRICH. Ein Massenflug von Calliptamus italicus L. (Orth. Acrid.) *Mitteil. Deutschen Ent. Ges.* 2(2): 26-27. 1931.—Report of great destructive swarms of locusts, at Darmstadt, not only *Calliptamus italicus,* but also several other spp.

11850. ZEUNER, FRIEDRICH. Beiträge zur deutschen Orthopterenfauna. *Mitteil. Deutsch. Ent. Ges.* 2(5): 75-78. 1931.—Remarks on *Stauroderus vagans* and 4 closely related spp. *Tettix kiefferi, Tettigonia caudata, T. viridissima,* and *T. cantans; Gampsocleis glabra; Podisma alpina* and *Isophya pyrenaea.*

SMALLER ORDERS OF INSECTA

(See also in B. A. 6(2): Entries 3311, 3328, 4661, 5779, 6043; 6(3): 6369, 7799, 8632, 8647, 8655, 8659; and in this issue 10914, 11820)

11851. AHRENS, WILLI. Ueber die Körpergliederung, die Haut und die Tracheenorgane der Termitenkönigin. (Fauna et Anatomia ceylanica, 4. Nr. 8). *Jenaische Zeitschr. Naturwiss.* 64(3): 449-530. 2 pl., 20 fig. 1930.—A detailed description is given of both gross and fine anatomy of the head*, thorax*, abdomen*, and tracheal organ* (Exsudatorgane of Holmgren) of a termite queen (*Termes redemanni*) based on material from Ceylon. Retrogression in the 1st abdominal sternite and initial stages in reduction of the following 3 segments are apparent from histological research. The hypodermis* (epidermis) of the abdominal integument is rich in glands below the brown pigment of the sclerites, in which region cell walls have disappeared giving a syncytial appearance of the tissue. Elongate, unicellular glands which open to the exterior contain tricogens. In the intersegmental membrane, however, glandular elements are entirely lacking and the cells are regular in shape and uniformly arranged. In areas with especially heavily chitinized cuticula, a characteristic degeneration occurs.

Typical apodemes distinguished by their manifold ramifications, arise from the basement membrane and give support and strength to the protoplasmic fibrillae. A significant differentiation in the cuticula occurs at the periphery where a dark border consisting, apparently, of dark-staining nuclei or small rods (secretion centers) lying in a denser zone of protoplasm, may be observed; not infrequently in place of these rod-like bodies a row of alveoli is found. The dermis is composed of dark and light lamellae, the former due, possibly, to protoplasmic changes, the latter formed from secretions; none of the dermal layers are definitely barred or striated. The tracheal epithelium has, as pointed out by Bugnion, an influence on the blood composition. The author therefore proposes to speak of it as a tracheal rather than as an excretory organ, since its relation to other excretory organs is not proved. Since the tracheal organ does not develop from the fat body as supposed by Holmgren, it may be assumed to have no influence on caste differentiation.—*W. Ahrens (transl.)*.

11852. BATHELLIER, JEAN. Contribution à l'étude systématique et biologique des termites de l'Indochine. 240p. 13 pl. 113 fig. Societe d'Editions Geographiques, Maritimes et Coloniales: Paris. 1927. Pr. 80 fr. [See B. A. 3(7/8): entry 16763.]

11853. CHAPMAN, PAUL J. Corrodentia of the United States of America: I. Suborder Isotecnomera. *Jour. New York Ent. Soc.* 38(3): 219-290; (4): 319-403. 10 pl. 1930.—Keys to the families, subfamilies, and genera of Isotecnomera in the U. S. Peripsocinae: *Peripsocus,* key to 5 spp.; *P.* **stagnivagus** ♀* (p. 376), N. Carolina (type), and S. Carolina. Many other previously known spp. are described and illustrated.

11854. DENIS, J. R. Notes sur les Aptérygotes. Le dimorphisme sexuel d'Archisotoma besselsi (Pack.) *Bull. Soc. Zool. France* 51(1): 16-19. 2 fig. 1926.

11855. HANDSCHIN, EDUARD. Collembola from Mexico. *Jour. Linnean Soc. London Zool.* 36(247): 533-552. 35 fig. 1928.—Treats of *Hypogastrura armata* Nic., *H. matura* v. **mexicana*** (p. 535); *H. copiosa* Fols., *Schöttella* **nodiseta*** (p. 536); *Xenylla nitida* Tull., *Pseudachorutes complexus* McG., *Achorutes muscorum* Templ., *A.* **barberi*** (*A. quadrioculata** Fols.) (p. 537), *Tullbergia collis* v. **mexicana*** (p. 538), *Proisotoma* **intermixta*** (p. 539), *Isotoma minor* Schäf., *I. viridis* Bourl., *Tomocerus flavescens* v. *americanus* Schtt, *Isotomurus palustris* Müll., *Entomobrya decemfasciata* Pack., *Lepidocyrtus cyaneus* Tull., *Lepidocyrtinus mexicanus* Fols., *L.* **semicoloratus*** (p. 544), *Heteromurus* **mexicanus*** (p. 545), *Sminthurinus aureus quadrilineata* Tull., *S. quadrimaculatus* Ryd., *Ptenothrix testudineatus* Fols. The close affinity of the Mexican collembolan fauna to that of N. Amer. is noted. The author presents arguments in favor of using the name *Hypogastrura.* Collembola of: (1) Hot and semi-desert regions; (2) mountain-forests; and (3) snow-regions are discussed. *J. W. Folsom.*

11856. HOOD, J. DOUGLAS. Two Urothripidae (Thysanoptera) from Florida, with keys to the known genera and the North American species. *Bull. Brooklyn Ent. Soc.* 24(5): 314-322. 1 pl. 1929.—Consideration of group characters and key to genera; **TRACHYTHRIPS** (p. 317), near *Bebelothrips,* type *T.* **watsoni*** (p. 317); *Stephanothrips,* key to spp.; *S. occidentalis* H. & W., new to U. S. A.

11857. JACKSON, C. H. N. The Collembola of Wicken Fen, Cambridgeshire. *Nat. Hist. Wicken Fen* 4. 300-307. 1 pl. 1928.

11858. KEILIN, D., and G. H. F. NUTTALL. Iconographic studies of Pediculus humanus. *Parasitology* 22 (1): 1-10. 18 pl. 1930.—This series of beautifully executed plates presents in detail the internal and external anatomical structures of *P. humanus* with exception of the mouthparts. The plates are fully explained, and include one of *Phthirus pubis* for comparison. Attention is directed to the priority of *P. humanus* race corporis de Geer, 1778 over *P. h.* race *vestimenti* Nitzsch, 1818. *Phthirus* (not *Phthirius*) is the correct spelling for the genus as established by Leach.—*A. E. Miller.*

11859. SILVESTRI, F. Contributions to a knowledge of the Indo-Malayan Japygidae (Thysanura). *Rec. Indian Mus.* 32(4): 439-489. 51 fig. 1930.—A preliminary account of the Japygidae from the region is given. The material dealt with includes 26 spp. and varieties of which 7 are provisionally referred to the genus *Japyx* Hal., 16 (varieties included) to *Indjapyx,* 2 to *Burmjapyx,* and 1 to *Parajapyx.* The author believes that the true form of *Japyx indicus* Oud. is confined to Sumatra and that specimens taken elsewhere, but hitherto grouped together as *J. indicus,* actually constitute other species, subspecies, and varieties. The folowing are described in Latin: *Japyx syriacus* v. **inferior*** (p. 439) and *J.* **evansi*** (p. 440), Mesopotamia; *J.* **beccarii*** (p. 442), Borneo, type in Sarawak Mus.; *J.* **greeni*** (p. 444), Ceylon; *J.* **immsi*** (p. 447), India; *J.* **murudensis*** (p. 449), Borneo; **INDJAPYX** (p. 451), type *I.* **indicus*** (*Japyx i.* Oud.) (p. 451), Sumatra, with varieties: **separata*** (p. 454), Riouw Arch., **javana*** (p. 456), Java, **divisa*** (p. 458), Flores Is., Dutch E. Indies, **birmana*** (p. 459), Burma, **borneensis*** (p. 462) and **bidicola*** (p. 463), Borneo; *I.* **ceylonicus*** (p. 465), Ceylon; *I.* **kraepelini*** (p. 467), Java, type in Mus. Hamburg; *I.* **heteronotus*** (p. 469), India; *I.* **annandalei*** (p. 471), with var. **bituberculata*** (p. 473), Bombay; *I.* **seymourii*** (p. 475), *I.* **pruthii*** (p. 477) and *I.* **gravelyi*** (p. 479) (type in Madras Mus.), India; *I.* **taprobanicus*** (p. 481), Ceylon; **BURMJAPYX** (p. 483), type *B.* **oudemansi*** (*Japyx o.* Parona) (p. 484); *B.* **paronae*** (p. 487).—*S. Ribeiro.*

11860. SJÖSTEDT, YNGVE. Eine neue Termite aus Katanga, Belg. Kongo. *Ent. Tidskr.* [*Stockholm*] 48(3): 169. 1 fig. 1927.—*Megagnathotermes* **katangensis*** (p. 169), Soldier, type in Mus. Stockholm.

11861. STACH, JAN. Zwei neue Collembolen aus Ungarn. *Ann. Mus. Nat. Hungarici* 24: 81-86. 1 pl. 1926. —*Xenylla* **birôi*** (p. 81), resembling *X. börneri* Axels.; *Deuterosminthurus* **fenyesi*** (p. 82), resembling *D. pallipes* (Lubb.). A synoptic table of all *Deuterosminthurus* spp. in which the unguiculi are alike on all feet, is given. —*J. Stach (transl. by J. W. Folsom).*

11862. [TIFLOV, V. E.] ТИФЛОВ, В. Е. Блохи водяных крыс (Arvicola amphibius) Юго-Востока РСФСР. (The fleas of water rats. (A. amphibius) in the southeast of the RSFSR.) Вестник Микробиологии,

Эпидемиологии и Паразитологии (*Rev. Microbiol., Épidémiol. et Parasitol.*) 9(2): 263-268. [English summary p. 288.] 2 fig. 1930.—Out of 829 fleas taken from 136 water rats and 32 nests in the province of Orenburg, 87% were *Ceratophyllus walkeri* Roth., and the remaining 12.53% were *C. penicilliger, C. mustelae, C. consimilis, Ctenophthalmus wagneri, C. breviatus, C. orientalis,* and *Hystrichopsylla talpae.* The author stresses the fact that *C. walkeri* (described) which so far was known only in Great Britain, was found in Russia.—*G. A. Lebedeff.*

11863. WOMERSLEY, H. Sinella myrmecophila Reut. (Collembola) in Britain. *Ent. Month. Mag.* 64(774): 247. 1928.

CYCLOSTOMATA, ELASMOBRANCHII, AND PISCES

BARTON WARREN EVERMANN, *Editor*

H. WALTON CLARK, *Associate Editor*

(See also in this issue Entries 9114, 9121, 9693, 9760, 9863, 9867, 9879, 9894, 9947, 10021, 10024, 10113, 10153, 10218, 10460, 10461, 10474, 10475, 10477, 10601, 10771, 10799, 10940, 11222, 11252, 11262, 11297, 11306, 11464, 11466, 11467, 11488, 11524, 11526)

11867. BLAKE, ISOBEL. The external disinfection of fish ova with reference to the prophylaxis of furunculosis. *Fishery Board for Scotland, Salmon Fisheries, 1930,* No. II. 10pp. 1931.—The introduction discusses the general theory of the actions of disinfectants; this is followed by tables giving methods and results of the determination of lethal concentrations of germicides (acriflavine, brilliant green, chlorine, phenol, and potassium permanganate) for *Bacillus salmonicidus.* The effect of the above-mentioned germicides on the viability of trout ova and the practical application of acriflavine as a disinfectant of ova are discussed. A summary and references to literature are given. The author's conclusions are as follows: Ova may be regarded as a possible means of spread of furunculosis; *B. salmonicidus,* if carried by ova, is on the surface and not in the interior of the ova; ova may be disinfected without injury by application of certain germicides; acriflavine has been found to be a suitable disinfecting agent. At a concentration of 1 in 2000, this substance destroys *B. salmonicidus* and is practically non-injurious to ova, when applied for 20-30 minutes. The germicidal effect of acriflavine is not greatly diminished by the presence of organic matter in the water; disinfection by acriflavine is easily carried out, and the cost is relatively small.—*Evermann and Clark.*

11868. BRYANT, WILLIAM L. Supplementary note on Coccosteus angustus. *New York State Mus. Bull.* 286. p. 153. 1931.—*C.* **involutus** (*C. angustus* Bryant, preoc.).

11869. BURKE, VICTOR. Revision of the fishes of the family Liparidae. *U. S. Nation. Mus. Bull.* 150. 1-204. 110 fig. 1930.—A taxonomic report based chiefly on a comparative study of material in the Amer. Mus., the Mus. of Comparative Zool., the U. S. Nat. Mus., the U. S. Bureau of Fisheries, and the Stanford Univ. Zool. Mus. Accounts of species not examined, but recognizable from descriptions, are also included. The author examined about 830 specimens representing 90 spp. Altogether 13 genera and 114 spp. are recognized. The first part of the paper contains a discussion of the various characters used in classification, their modifications, and the probable lines of phylogenetic development; the structure of the dorsal fin; the geographical and vertical distribution of these fishes, from shallow tide pools to great ocean depths. It also contains directions for collecting and preserving these soft-bodied fishes; a brief historical account of the family; and an account of their bionomics. The 2nd part contains descriptions of the genera and species, beginning with a discussion of the probable relationship of the genera. Under each of the 3 genera (*Liparis, Careproctus, Paraliparis*) containing numerous species, a rather lengthy discussion of the structural characters used in classification and the distribution of the species, are given, similar to that of the first part which treats of the family as a whole. Dichotomus keys to the genera and species are given. The paper contains many figures, mostly outline drawings of teeth, which are of importance in identification. *Liparus mucosus* Ayres (=*Neoliparis florae* Jordan & Starks); *L.* **rhodosoma** (p. 81), Okhotsk Sea, 75 fathoms; *Careproctus* **abbreviatus*** (p. 128), south of Alaska Pen., 625 fathoms; **TEMNOCORA** (p. 146), type *T.* **candida** (*Careproctus candidus* Gilbert & Burke) (p. 146); *Careproctus* **jordani** (*C. gilberti* Jordan & Thompson preocc.) (p. 192); types of new sp. in Stanford Univ. Zool. Mus. The author questions the propriety of referring *Gymnolicodes edwardsi* Vaillant to the Discoboli. A partial bibliography is appended.—*I. Ginsburg.*

11870. CAPRA, F. Osservazioni sul Percus strictus e forme affini. *Ann. Mus. Civ. Storia Nat. Genova* 52: 181-190. 1925/1928.—*Percus strictus* v. folchinii (Dodero i. l.) (p. 188), Asinara Isl. Catalogue of the subspp., vars. and synonyms of *Percus strictus.*

11871. LAVERDIÈRE, J. W. Description d'une plaque osseuse d'Heterosteus (groupe des Arthrodira) du Frasnien de Trélon (Nord de la France). *Ann. Soc. Geol. du Nord* 55: 61-70. 1 pl. 7 fig. 1930.—Several plates, including an anterior dorso-lateral plate, from the basal upper Devonian, are described and referred to the genus *Heterosteus.* This is the first reported account of the fossil from the Baltic region and also the first record of occurrence so high up in the Devonian.—*W. Berry.*

11872. LEBER, A. Über Tetrodonvergiftung. *Hamburg Univ. Abhandl. Gebiet Auslandsk.* 26: 641-643. 2 pl. 1927.—A case of violent poisoning following the ingestion of some flesh of the fish *Tetrodon* (probably *immaculatus*) is reported. The symptoms and successful treatment are described.—*L. W. Butz.*

11873. NICHOLS, J. T. Speculations on the history of the Ostariophysi. *Copeia* 1930(4): 148-151. 1930.—The suckers are considered more primitive than and more or less ancestral to the true carps, the whole group

of carp-like fishes to have pemanently lost oral dentition by passing through the sucker form. Southern Asia, perhaps more specifically China, seems to have been the recent center of differentiation and dispersal for this group. The loaches, though somewhat catfish-like superficially, are thought to have no near relationship with the catfishes, but to be a modern derivative from the true carps. The carps are unquestionably more recent than catfishes or characins, and their distribution has been from the north. The earlier distribution of catfishes and characins has presumably followed the same course. Resemblances in species of these 2 groups in Africa and S. Amer. are superficial, and their evolutionary diversification in the respective continents seems to have been entirely independent. Structurally catfishes are more specialized than characins, and ancestral Ostariophysi should have been characin-like, but there is some evidence that the distribution of modern catfishes was earlier than that of modern characins. The Ostariophysi seem to be a Tertiary group, existing and perhaps in much their present form throughout the Tertiary, but with closer relationships to more primitive pre-Tertiary fishes uncertain. They seem always to have been continental fresh-water fishes, a few catfishes only having become marine, these marine forms now occurring in salt water, and also having relatives in Australian fresh waters.—*J. T. Nichols.*

11874. PEYER, B. Rochen-Eikapseln aus den Horwerschichten (unteres Stampien) von Grieigen, Kt. Luzern. *Eclogae Geol. Helvetiae* 21(2): 407-413. 1 pl. 1928.—The author describes and figures 4 new-found egg-cases and compares them with *Raia helvetica.*—*W. Berry.*

11875. PIETSCHMANN, VICTOR. Remarks on Pacific fishes. *Bernice P. Bishop Mus. Bull.* 73. 24p. 4 pl. 4 fig. 1930.—Since the publication of Fowler's comprehensive work on the Fishes of Oceania a number of undetermined fishes have been received at Bernice P. Bishop Mus., some from the Honolulu fish market, others from various parts of Oahu. Notes or descriptions are given of 41 spp., including *Echinorhinus* **cookei*** (p. 4), Kauai; *Cypselurus* **gregoryi*** (p. 7), Pearl and Hermes Reef; *Ptenonotus* **melanogeneion*** (p. 8) and *Ichthyocampus* **edmondsoni** (p. 8), Waikiki Reef, Honolulu; types in Bernice P. Bishop Mus. In the synonymy of *Thalassoma purpureum* are included *T. umbrostigma* (Rüppell) and *T. berendti* Seale, which a comparison of many specimens show to be the same. *Crayracion manillensis* Bleeker is the young of *Tetrodon immaculatus* Bloch & Schneider.—*Evermann & Clark.*

11876. PRUVOST, PIERRE. Sur un poisson fossile trouvé dans le terrain houiller de l'Escarpelle. *Ann. Soc. Geol. du Nord* 53: 296-298. 1928.—Discusses the occurrence of *Rhadinichthys planti* from the coal regions of Escarpelle, northern France.—*W. Berry.*

11877. REY, LUIS LOZANO. Los "Dentex" de España y del Marruecos español. [The species of Dentex of Spain and Spanish Morocco.] *Trab. Mus. Nacion. Cien. Nat. Zool.* 55. 1-24. 2 pl., 2 fig. 1930.—The author gives a systematic account of the 4 Mediterranean spp., including a key, synonymies, common names, descriptions, distribution, economic value, and figures of each.

11878. RIMSKY-KORSAKOFF, V. N. The food of certain fishes of the Lake Champlain watershed. (III of A biological survey of the Champlain watershed.) *Suppl. to 19th. Ann. Rept. New York Conserv. Dept.* 1929. p. 88-104. 1930.—This paper is based upon examination of the alimentary tracts of 2,465 fishes taken in summer. Tables show the percentage of the various kinds of food taken by individuals of stated length, and also give the identification of the food items (often to genus, and sometimes to species). The small fishes are in no way selective as to the kind of Crustacea they feed upon, both Copepoda and Cladocera being taken in about equal amounts. Comparatively few species (*Coregonus clupeaformis* and *Catostomus commersonnii*) feed mostly upon mollusks. Mayfly nymphs, midge larvae, and caddisfly larvae are the most important kinds of insect food. Practically no fish eggs were found in the alimentary tracts. The most important constituents in the diet of fish-eating species were: *Perca flavescens, Boleosoma nigrum olmstedi, Osmerus mordax, Notemigonus crysoleuca,* minnows (Cyprinidae), and sunfishes (Centrarchidae). *Lepisosteus osseus* was found to be the most predacious fish-eating species.

11879. ROULE, LOUIS. Les attitudes des Hippocampes. *Bull. Mus. Nation. Hist. Nat.* [*Paris*] 1928(5): 313-315. 1928.—Swimming, resting, and feeding attitudes and mating behavior are described.

11880. ROULE, LOUIS. Présentation d'un squelette de Lampris luna L.-Gm. *Bull. Mus. Nation. Hist. Nat.* [*Paris*] 1(2): 133. 1929.—The elongations of the dorsal and pelvic fins are less pronounced in large individuals than in small ones. The pectoral and pelvic girdles are of considerable size in a small individual.

11881. SANZO, L. Peso specifico in uova de Exocoetus e portata biologica dei filamenti di attacco di esse uova a corpi solidi galeggianti. [Specific gravity of eggs of Exocoetus and biological significance of their adhering filaments to floating bodies.] *Boll. Soc. Ital. Biol. Sperim.* 5(6): 1008-1009. 1930.—The specific gravity of eggs of the flying fish *Exocoetus* being greater than that of surface marine water, they are suspended to floating bodies by means of special filaments. Without adhering to these bodies, they would sink deeper in the sea, where the density of water would not correspond to the natural habitat of the developing larvae.—*M. Comel.*

11882. SELLA, MASSIMO. The tuna (Thunnus thynnus L.) of the western Atlantic. An appeal to fishermen for the collection of hooks found in tuna fish. *Internat. Rev. Ges. Hydrobiol. u. Hydrograph.* 25(1/2): 46-67. 2 maps, 8 fig. 1931.—The seasonal and geographical occurrence and the economic importance of *T. thynnus* in Canada and the U. S. A. are discussed. Accurate morphological comparisons of the European and western Atlantic tuna would probably not only settle the questions of the affinity and taxonomic status of the European and American forms, but would also afford evidence as to whether tuna actually cross the Atlantic or not. The migrations of these fish were formerly considered as limited to the Mediterranean and Spanish waters. Both eastern and western tuna are classified as *Thunnus thynnus* L., since the American species, *T. secundodorsalis*, was apparently based on characters which are not distinguishable from those of *T. thynnus.* A special appeal is made for hooks found in tuna, with view to settling, if possible, the mooted question of migrations of tuna across the Atlantic.—*M. Sella.*

11883. SCHMIDT, P. A revision of the genus Hemilepidotus Cuvier (Pisces, Cottidae) and of the allied genera. Ежегодник Зоологического Музея, Академия Наук Ленинград (*Ann. Mus. Zool. Acad. Sci. Leningrad*) 30 (3): 359-369. 1929.—This paper is based upon a collection made by the Hydrographic Exped. of the Pacific Ocean. *Hemilepidotus, Melletes,* and *Calycilepidotus* form a separate group of the Cottidae, characteristic of the north Pacific. A key to the 6 forms is given. The account of each form includes synonymy, taxonomic remarks, and distribution. *Hemilepidotus hemilepidotus* **jordani** (*H. jordani* Bean) (p. 362).

11884. SCHMIDT, P. On the Japanese shark Halaelurus torazame (Tanaka). Доклады Академии Наук СССР., Сер. A. (*Compt. Rend. Acad. Sci. URSS., Sér. A.*) 1930(9): 223-227. 2 fig. 1930.—*H. torazame** (Tanaka) (=*Scylliorhinus rudis* Pietsch.) redescribed.

11885. SCHMIDT, P., and G. LINDBERG. A list of fishes, collected in Tsuruga (Japan) by W. Roszkowski. Известия Академии Наук СССР., Отделение Физико-Математических Наук (*Bull. Acad. Sci. URSS., Cl. Sci. Phys.-Math.*) 1930(10): 1135-1150. 1 fig. 1930.—This is a report on 84 spp. belonging to 48 families; among them are 15 spp. that occur also near Vladivostok. Northern spp. are completely absent. The systematic account includes records of locality, date, and length, with descriptive notes on some spp.

11886. SCOTT, WILLIAM BERRYMAN. On certain Silurian fish-like forms from Norway. *Proc. Amer. Phil. Soc.* 69(6): 391-396. 1930.—The recent discovery by Kiaer of an abundance of Silurian Anaspida fossils in Norway, helps considerably in clearing up the obscured phylogenetic status of the Cyclostomata. They show that the unpaired olfactory organ, the pouched gills, absence of jaws, true teeth and of paired fins date back to the Silurian. The sucking, disc-like mouth, set with rows of horny teeth, may be regarded as a unique specialization.—*J. H. Wales.*

11887. [SOKOLINSKIĬ, N. N.] СОКОЛИНСКИЙ, Н. Н. Новый подвид усача Barbus capito serratus subsp. n. [A new subsp. of barbel.] Известия Азербайджанского Государственного Университета имени Ленина, Отдел Естествознание и Медицина (*Annals V. I. Lenin State Univ. Azerbaijan, Sect. Nat. Hist. & Med.*) 6: 173-176. 1927.—*B. c.* serratus (p. 173), Caspian Sea.

11888. STEKHOVEN, J. H. SCHUURMANS, Jr. Einige Beobachtungen über die Bewegungen der Seenadel. *Zool. Anz.* 92(5/6): 141-146. 1930.—An aquarium collection of pipefish, *Syngnathus typhle,* from 10-12 cm. long was studied at the Netherlands Zool. Station at Helder. Their normal resting position in aquarium was not horizontal, but with the tail curving dorsally and the body slanting vertically upward. In swimming only the pectorals are used, the dorsal held rigid and the tail dragged as a rudder, the fore part of the body oblique, the dorsal surface approximately parallel to the surface of the water. If the tail is irritated, the animal moves its dorsal fin and swims away from the irritant in a horizontal position. Thus disturbance of the tail is seen to set up an escape reflex in the dorsal fin. The author agrees with Weber, who experimented on seahorses, that this is a cerebral reflex. Observations, and experiments with amputating greater or less portions of the tail showed following results: The tail is the anchor enabling *Syngnathus* to stay on or near the bottom. The tail never rolls up ventrally as in *Hippocampus.* Grasping does not belong to the normal behaviour of this animal as it does to the seahorse. The horizontal position assumed in escape is not its normal position. The tail when incited or injured moves away from the irritant, instead, like *Hippocampus,* of toward it. Thus reflexes in the pipefish in many respects, such as releasing movements of the dorsal fin, use of the tail as steering apparatus, of the pectoral fins in forward progression, resemble those of the seahorse, but the tail movements and reflexes causing them are different due to the entirely different structure of the 2 animals. —*F. LaMonte.*

11889. THOMPSON, DAVID H., and FRANCIS D. HUNT. The fishes of Champaign County. A study of the distribution and abundance of fishes in small streams. *Illinois Dept. Registr. & Educ. Div. Nat. Hist. Surv. Bull.* 19(1): 1-101. 52 map. 1930.—An intensive study of the abundance, distribution, and ecology of fishes resulting in an almost quantitative tabulation of data due to the restricted area of investigation. Physical characteristics of streams vary as functions of seasonal change, and parallel variations occur in streams of the same size. About 32 or so common aquatic plants have been observed in the streams of Champaign County. There were 132 quantitative collections made ranging through the entire year of 1928 and including 28,905 specimens represented by a water area of 9,535 sq. yds. Nine type habitats occur in the county: (1) vernal rivulets, (2) kettle holes at mouths of tile drains, (3) oxbow ponds along small streams, (4) permanent headwater streams, (5) stretches of shallow, sluggish water, (6) gravelly and sandy riffles, (7) rocky rapids and riffles, (8) moderately deep, smoothly flowing stretches, and (9) long, deep pools. One of the 74 spp, reported from the county is represented by 6,440 specimens, while 12 others are represented by a single specimen each. This extreme variation of abundance becomes explicable only through a thorough study of ecology. Soil fertility indirectly affects the number of fish in the neighboring region. Species reaching greatest abundance at certain points in a stream also reach greatest abundance in other streams at points with the same drainage area regardless of distance from source. Number of fish is inversely proportional to the amount of pollution; lack of sufficient oxygen content in the water being the cause. *Semotilus atromaculatus* was most tolerant to sewage. Distribution depends largely upon 3 factors: (1) Vegetation, (2) depth of water, and (3) kind of bottom and rate of flow. There exists a close correlation between morphological adaptations and habitat. Migration in small streams is a definite procedure with many fish, referable to the time of year and spawning habits. Of the 74 spp. taken within the county, there are 17 that are absent from one or more of the 6 stream systems. Most of these, however, when introduced into streams from which they were originally absent often become well established. The explanation for the association of different species of fish probably lies in similar environmental predilections, that of *Notropis cornutus* and *Hybopsis kentuckiensis* being the most extraordinary. Analytical keys together with data on distribution and abundance for each species are given.—*J. Piatt.*

11890. VINCIGUERRA, D. Sopra una collezione di pesci della Palestina. *Ann. Mus. Civ. Storia Nat. Genova* 52: 210-226. 1925/1928.—Descriptive data on 16 spp., including *Barbus* continii (p. 221), Palestine.

11891. VINCIGUERRA, D. Enumerazione di alcune specie di pesci della Somalia italiana raccolte dal March. Saverio Patrizi. *Ann. Mus. Civ. Storia Nat. Genova* 52: 246-259. 2 fig. 1925/1928.—Records and remarks on 16 spp. including *Labeo* grammipleura (p. 248) and *Fundulus* patrizii ♂* ♀* (p. 254). Types in Mus. Civ. Genova.

11892. [VORONTSOV, E. M.] ВОРОНЦОВ, Е. М. Материалы по ихтиофауне Днепровского бассейна. II. Рыбы и рыболовство среднего течения р. Десны. [Ichthyofauna of the Dnieper Basin. II. Fishes and fishing in the middle part of the River Desna.] [German summary.] Смоленский Государственный Университет, Научные Известия (*Universität Smolensk, Wiss. Mitteil.*) 5(1): 63-76. 1928.—An annotated list of 36 spp. A table shows the distribution of spp. in this and other parts of the Dnieper Basin.

11893. WHITE, E. GRACE. The whale shark, Rhineodon typus. Description of the skeletal parts and classification based on the Marathon [Florida] specimen captured in 1923. *Bull. Amer. Mus. Nat. Hist.* 61(4): 129-160. 9 pl., 12 fig. 1930.—A critical review of the classification of the different groups of sharks based on anatomical characters. The author gives external measurements of the specimen, and discusses the occipital region of the cranium; the characters of the trunk vertebrae, including a cross section; the visceral arches; the dental bands, and the detailed morphology of the claspers (myxopterygia). Different authors have held varying views of the relationship of the whale shark. Regan considered it allied to the nurse sharks (Orectolobidae); Müller and Henle, and Jordan and Evermann assigned its relationship to the isuroids. On the basis of available data the author assigns it to the latter position. She gives an analysis of its characters with other indications of relationships grouped under class, subclass, etc. Characters of suborders of sharks are compared with corresponding characters of *Rhineodon.* A bibliography is included.

AMPHIBIA AND REPTILIA

G. K. NOBLE, *Editor*, Amphibia
KARL PATTERSON SCHMIDT, *Editor*, Reptilia

(See also in this issue Entries 9196, 9863, 11247, 11252, 11452, 11526)

GENERAL

11894. BOND, HARLEY D. Some amphibians and reptiles of Monongalia County, West Virginia. *Copeia* 1931(2): 53-54. 1931.—Annotated list of 19 amphibians and 16 reptiles.

11895. BURT, CHARLES E. A report on some amphibians and reptiles from New York and New Jersey. *Jour. Washington Acad. Sci.* 21(9): 198-203. 1931.—Locality data and ecological notes on 6 salamanders, 2 toads, 7 frogs, 2 lizards and 3 snakes.

11896. CORRINGTON, JULIAN D. Abnormal herpetological specimens from Syracuse, New York. *Amer. Naturalist* 65(696): 77-85. 1931.—A spotless *Ambystoma maculatum*, a white-bellied *Storeria occipito-maculata*, and an albino *Necturus maculosus*.

11897. LOGIER, E. B. S. A faunal investigation of Long Point and vicinity, Norfolk County, Ontario. IV. The amphibians and reptiles of Long Point. *Trans. Roy. Canadian Inst.* 18(1): 229-236. 1931.—An annotated list of 6 amphibians, 6 snakes, and 6 turtles. This area is noteworthy for the apparent absence of *Ambystoma, Plethodon*, all Hylidae, *Rana clamitans*, and *R. sylvatica*, for the scarcity of *Bufo americanus*, and for the abundance and pronounced melanistic tendency of *Thamnophis s. sirtalis*. The abundance of the last sp. probably accounts for the scarcity of amphibians.

11898. POPE, T. E. B. Wisconsin herpetological notes. *Trans. Wisconsin Acad. Sci. Arts and Lett.* 26: 321-329. 1931.—Distributional notes on about 40 spp. of Amphibia and Reptilia.

11899. SLEVIN, JOSEPH R. Range extensions of certain western species of reptiles and amphibians. *Copeia* 1931(3): 140-141. 1931.—*Eleutherodactylus augusti* new to Arizona: *Dermochelys schlegelii*, range on Pacific coast extended north to Marin County, California; slight range extensions of several other spp. noted.

11900. SMITH, MALCOLM A. The Reptilia and Amphibia of the Malay Peninsula from the Isthmus of Kra to Singapore including the adjacent islands (A supplement to Dr. G. A. Boulenger's Reptilia and Batrachia, 1912). *Bull. Raffles Mus.* [*Singapore*] 3. 149p. 13 fig. 1930.—This report supplements G. A. Boulenger's Fauna of the Malay Pen. (Reptilia and Batrachia), adding to his list of spp. 1 turtle, 16 lizards, 12 snakes, and 18 amphibians. Keys for many genera and species are provided and complete descriptions are given of all those added since 1912. Attention is also directed to the curious discontinuous distribution of a considerable number of species found in the northern part of the peninsula and in the Malay Arch., but not in the southern part of the peninsula. The list includes a crocodile, a turtle, several lizards, snakes (including sea snakes), and amphibians. *Rana cancrivora* **raja** (p. 97), "Patani town." A bibliography of 41 titles, mostly recent literature dealing with the fauna of the Malay Pen. is added.—*S. C. Bishop.*

11901. SMITH, MALCOLM A. (Introduction by F. N. CHASEN.) The herpetology of Mt. Kinabalu, North Borneo, 13,455 ft. *Bull. Raffles Mus.* [*Singapore*] 5. 3-32. 2 pl., 3 fig. 1931.—In the introduction the faunal zones and collecting stations are described. The systematic report, dealing with 600 specimens collected by F. N. Chasen and H. M. Pendlebury, is divided into 3 parts. The first part is a list of the spp. arranged according to the altitudes at which they were collected. The second part is a systematic account of the collection, with locality records, descriptive notes, and taxonomic remarks. *Leptobrachella*, emended diagnosis; *L.* **baluensis*** (p. 12), 7200 ft.; *Nectophryne* **altitudinis*** (p. 14), 7200-10,200 ft.; *Phrynoglossus* Peters (=*Oreobatrachus* Blgr.); *Ooeidozyga* Kuhl & v. Hasselt (=*Osteosternum* Wu); *Philautus* Gistel (=*Nyctixalus* Blgr.); *P.* **amoenus*** (p. 18), 7200 ft.; *P. pictus* (Peters) (=*Rhacophorus anodon* van Kampen); *P. margaritifer* (Blgr.) (=*Ixalus flavosignatus* Bttg.); *P. aurifasciatus* (Schlegel) (=*Nyctixalus robinsoni* Annandale); *P.* **spiculatus*** [labeled *P. spiculosus* on pl. 1] (p. 20); *Lygosoma kinabaluensis* Bartlett is maintained as distinct from *L. variegatum*, and an emended description is given; *Natrix murudensis* M. A. Smith and *Oreocalamus hanitschi* Blgr., emended descriptions; *Calamaria* **pendleburyi** (p. 27); *C. grabowskyi* Fischer (=*C. baluensis* Blgr., *C. moultoni* Dunn); *Trimeresurus* **chaseni*** (p. 29). The third part lists the spp. known to inhabit the mt. above 3000 ft. Types of new spp. in Brit. Mus.

11902. STRECKER, JOHN K. Field notes on the herpetology of Wilbarger County, Texas. *Contrib. Baylor Univ. Mus.* 19. 3-9. 1929.—Annotated list of 9 amphibians, 8 lizards, 14 snakes, and 5 turtles.

11903. STRECKER, JOHN K. A preliminary list of the amphibians and reptiles of Tarrant County, Texas. *Contrib. Baylor Univ. Mus.* 19. 10-15. 1929.—Annotated list of 12 amphibians, 10 lizards, 20 snakes, and 6 turtles. The spp. belong to the fauna of eastern Texas rather than of western Texas.

AMPHIBIA

11904. BARBOUR, THOMAS. Another introduced frog in North America. *Copeia* 1931(3): 140. 1931.—*Hyla septentrionalis* at Key West, Florida, presumably introduced from Cuba.

11905. CAMPBELL, BERRY. Notes on Batrachoseps. *Copeia* 1931(3): 131-134. 1931.—The range of *B. a. attenuatus* is found to overlap those of *B. a. major* and *B. a. pacificus*. The forms of this genus, recently regarded as conspecific, are therefore separated into 2 spp., each with 3 subspp.: *B. a. attenuatus; B. a. caudatus; B. a. leucopus; B. pacificus pacificus; B. p.* **major** (*B. m.* Camp.) (p. 133); and *B. p.* **catalinae** (*B. c.* Dunn) (p. 133).

11906. FEDOROWICZ, Z. Żaba zwinka (Rana agilis Thom.) z Nieświeża. [R. agilis in NE. Poland.] [With German summary.] *Kosmos* [*Lwów*] 55(3/4): 737-738. 1930(1931).—The northern limit of the range of *R. agilis* in Central Europe is extended to 53° 15′ N. in Poland.

11907. KLAUBER, L. M. An addition to the fauna of Lower California. *Copeia* 1931(3): 141. 1931.—*Bufo californicus*.

11908. LOYER, M. Les crapauds d'Ouargla [Algeria]. *Rev. Hist. Nat. Pt. 1. B. Aquicult., Ent., Aquar. et Terrar.* 10(12): 410-416. 1929.—Description of habits of *Bufo pantherinus* and *B. viridis*.

11909. MOFFAT, C. B. December tadpoles. *Irish Nat. Jour.* 3(11): 230-231. 1931.—Notes on the continuance of frog tadpoles in the tadpole stage into Dec. and Jan., in Ireland.

11910. MOHR, CHARLES E. Observations on the early breeding habits of Ambystoma jeffersonianum in central Pennsylvania. *Copeia* 1931(3): 102-104. 2 fig. 1931.—First description of the spermatophore* of this sp. The courtship behavior, also described, is similar to that of *A. maculatum*.

11911. MYERS, GEORGE S. The original descriptions of Bufo fowleri and Bufo americanus. *Copeia* 1931(3): 94-96. 1931.—The authorship of *B. fowleri*, generally credited to Garman (1884), is shown to belong to Hinckley (1882). *B. americanus* Holbrook is considered a composite sp., and the name is restricted to the sp. cur-

rently known as *B. americanus*, instead of to the one now known as *B. fowleri*.

11912. **OYAMA, JUNJI.** Note on the color pattern of Hynobius stejnegeri Dunn. *Copeia* 1931(3): 86. 1931.

11913. **PIATT, JEAN.** An albino salamander. *Copeia* 1931(1): 29. 1931.—*Plethodon glutinosus*, in Indiana.

11914. **SCHMIDT, KARL P.** A new toad from Korea. *Copeia* 1931(3): 93-94. 1 fig. 1931.—*Bufo* stejnegeri* (p. 94), type in Field Mus. Nat. Hist.

11915. **SMEDLEY, N.** Notes on the giant frog, Rana macrodon. *Bull. Raffles Mus.* 5. [59]-[62]. 1931.—Two forms of this sp., one broad-headed and the other narrow-headed, are found in the Indo-Malayan region. The former seems absent in Sumatra and the latter in Java, but otherwise both forms occur throughout the western part of the Malay Arch. Measurements of a series of specimens are given.

11916. **SVIHLA, ARTHUR.** An extension of the range of Dicamptodon ensatus. *Copeia* 1931(3): 143. 1931.—To eastern Washington.

11917. **VAN KAMPEN, P. N., and L. D. BRONGERSMA.** Notes on a small collection of Amphibia from Sumba. *Treubia* 13(1): 15-18. 1931.—An annotated list of 5 spp. *Rana papua*, new to Sumba.

REPTILIA

11918. **BROOM, R.** Notices of some new genera and species of Karroo fossil reptiles. *Rec. Albany Mus.* [*Grahamstown*] 4(1): 161-166. 1931.—Therocephalia: **CYNARIOGNATHUS** (p. 161), erected for *C.* **platyrhinus** (*Pristerognathus p.* Broom) (p. 161); **ICTIDOSTOMA** (p. 161), erected for *I.* **hemburyi** (*Ictidognathus h.* Broom) (p. 161); **ICTIDOSUCHOIDES** (p. 162), erected for *I.* **longiceps** (*Ictidosuchus l.* Broom) (p. 162); *Whaitsia* **major** (p. 162), Orange Free State, type in author's coll.; **LYCIDEOPS** (p. 162), allied to *Whaitsia*, erected for *L.* **longiceps** (p. 162), Orange Free State, type in author's coll.; **EUCHAMBERSIA** (p. 163), resembling *Whaitsia*, erected for *E.* **mirabilis** (p. 163), Cape Province. Cynodontia: **CYRBASIODON** (p. 163), erected for *C.* **boycei** (p. 163), Natal, type in Durban Mus.; **CYNOSUCHOIDES** (p. 164), erected for *C.* **whaitsi** (*Cynosuchus w.* Haughton) (p. 164); *Lycaenognathus* **kannemeyeri** (p. 164), locality not stated, type in Albany Mus. Gorgonopsia: *Aelurosaurus* **breviceps** (p. 165), Cape Province, type in Am. Mus. Nat. Hist. Bauriamorpha: **MICROHELODON** (p. 165), erected for *M.* **eumerus** (*Microgomphodon e.* Seeley) (p. 165). Anomodontia: **CERATAELURUS** (p. 166), allied to *Pristerodon*, erected for *C.* **mirabilis** (p. 166), Cape Province, type in Am. Mus. Nat. Hist.; **MEGACYCLOPS** (p. 166), allied to *Eocyclops*, erected for *M.* **whaitsi** (p. 166), locality not stated, type in Cape Town Mus.

11919. **BURT, CHARLES E.** On the occurrence of a throat-fan in Callisaurus ventralis gabbii and two species of Crotaphytus. *Copeia* 1931(2): 58. 1931.—Apparently first record of this structure in these spp. Courtship display of *Callisaurus ventralis gabbii* described.

11920. **[CHERNOV, S. A.]** ЧЕРНОВ, С. А. О дальневосточных и китайских черепахах р. Amyda. [Far eastern and Chinese turtles of the genus Amyda.] Доклады Академии Наук СССР., Сер. А. (*Compt. Rend. Acad. Sci. URSS., Sér. A.*) 1930(10): 251-255. 1930.—Comparative study of *A. sinensis*, *A. schlegeli*, and *A. maacki* leads the author to assume that the last 2 spp. are merely young forms of *A. sinensis*.

11921. **DOLLFUS, ROBERT PH.** Notules herpétologiques marocaines. I. *Bull. Soc. Sci. Nat. Maroc* 9 (7/8): 112. 1929.—*Emys orbicularis*, *Hemidactylus turcicus*, and *Boodon lineatus* are new to Morocco.

11922. **DREVERMANN, FRITZ.** Das erste Skelett des Pflasterzahns Placodus, ein Geschenk Arthur V. Gwinner's. *Natur u. Mus.* [*Frankfurt a/M*] 61(4): 150-156 6 fig. 1931.—Account of the finding and preparation of a fairly complete skeleton of *Placodus** from the Muschelkalk of Germany, with a description of its chief characteristics. In the author's opinion this reptile, like the modern *Amblyrhynchus*, lived on the land but sought its food in the sea.

11923. **FORCE, EDITH R.** Habits and birth of young of the lined snake, Tropidoclonion lineatum (Hallowell). *Copeia* 1931(2): 51-53. 1931.—This sp. is abundant under debris near Tulsa, Oklahoma. It feeds upon earthworms. Broods of 2-12 individuals, from 70 to 130 mm. long, are born in August.

11924. **GRANT, CHAPMAN.** Notes on the Ameivas of Porto Rico. *Copeia* 1931(2): 61-62. 1931.—Coloration and habits of *A. exsul* and *A. wetmorei* described.

11925. **HARTWEG, NORMAN.** Apparent ovoviviparity in the Mexican skink, Eumeces lynxae Wiegmann. *Copeia* 1931(2): 61. 1931.—No previous record of ovoviviparity in this genus.

11926. **NOPCSA, FRANCIS.** On Troödon, a reply to Dr. C. W. Gilmore. *Ann. and Mag. Nat. Hist.* 43(8): 70-72. 1931.—The author refers the type skull of *Troödon* to the Acanthopholinae, but considers that the body skeleton described as *Troödon* belongs to another animal and will require a new generic name.

11927. **POPE, C. H.** A list of reptiles known to occur in Fukien Province, China. *Nat. Hist. Soc. Fukien Christian Univ. Foochow, China* 2: 20-22. 1929.—Six turtles, 16 lizards, and 62 snakes are listed.

11928. **VAN HYNING, O. C.** Reproduction of some Florida snakes. *Copeia* 1931(2): 59-60. 1931.—Notes on 8 spp. The distinctness of *Natrix sipedon fasciata* and *N. s. pictiventris* is questioned.

11929. **WETTSTEIN, OTTO.** Neue oder wenig bekannte Eidechsen. *Zool. Anz.* 95(11/12): 280-291. 5 fig. 1931.—*Lacerta sicula* **mertensi*** (*L. serpa major* Mertens not *L. viridis* v. *major* Blgr.) (p. 280); *L. sicula* **ragusae*** (p. 282), Dalmatia, type in Mus. Wien; *Ommateremias* Lantz, a subg. of *Eremias*, is not considered valid; several forms of *Eremias multiocellata* are reviewed, and an emended description of *E. m. planiceps* Strauch is given.

[Second definite capture of S. crepidatus in Trentino.] *Studi Trentini Sci. Nat.* 10(3): 203-209. 1 fig. 1929.—Record of one specimen, Oct. 26, with a review of the literature on the occurrence of the species in Italy.

11938. CHAPMAN, FRANK M. The bird life of Mt. Duida, Venezuela. *Science* 71(1846): 517. 1930.—Abstract.

11939. COMTE, A. Notes et observations biologiques sur les oiseaux des environs de Genève. Année 1929. *Bull. Soc. Zool. Genève* 4(2): 141-151. 1930.—Chiefly nesting notes on about 32 spp.

11940. CONNELL, CHARLES G. The black-necked grebe—first breeding records for Scotland. *Scottish Nat.* 1930(184): 105-109. 1930.—*Podiceps nigricollis* in the Forth area, in 1930.

11941. CORAINVILLE, COSTREL de, et al. Notes et faits divers. *Rev. Hist. Nat. Appliquée Pt. 2. Oiseau et Rev. Franç., Ornithol.* 11(6): 377-378. 1930.—De Corainville gives an account of the capture of the red-necked grebe (*Podiceps g. griseigena* Boddaert) in Calvados. L. BATIOT reports *Falco rusticolus candicans* Gm. on the coast of Vendée. MARCEL LEGENDRE presents notes on the birds of Paris. M. DAUPLAY reports the recovery of banded birds in Indo-China.

11942. CORLETT, GEOFFREY. The winter status of the Bass Rock Gannets. *British Birds* 24(2): 54-55. 1930.—Few individuals of *Sula bassana* are seen in Dec. and Jan. in the North Sea off Scotland. In Feb. numbers return to the vicinity of their breeding ground on Bass Rock.

11943. COWARD, T. A., et al. Notes from reservoirs and sewage farms. *British Birds* 23(9): 234-241. 1930.—T. A. Coward contributes notes on migration and habits of "Passage waders on a Cheshire sewage farm in the autumn of 1929." (pp. 234-236). A. W. BOYD gives migration data on various water birds in "Notes from Staffordshire reservoirs." (pp. 236-238). H. G. ALEXANDER writes on "Passage migrants at North Worcestershire reservoirs." (pp. 238-240), dealing chiefly with water birds. C. OLDHAM contributes notes on the migration and habits of "Spotted redshank and other migratory waders at Tring." (pp. 240-241).

11944. DOBBRICK, W. Eine neue Brutstelle vom Karmingimpel (Erythrina er. erythrina Pall.) im Danziger Gebiet. *Ornithol. Monatsschr.* 55(2): 29-30. 1930.—Several pairs and young of the Scarlet Bullfinch were found in 1929.

11945. DROST, [R.]. Ungewöhnliche Gäste auf Helgoland im Frühjahr 1929. *Der Vogelzug. Ber. ü. Vogelzugsforsch. u. Vogelberingung* 1(1): 46. 1930.—Hoopoe, cirl bunting, lesser grey and red-backed shrikes, red-footed falcon, *Merops apiaster*, and *Oenanthe hispanica*, were observed as Heligoland in the spring of 1929.

11946. DROST, RUDOLF, und HANS SCHILDMACHER. Zum Vogelzug im Nordseegebiet nach den Ergebnissen der Beobachtungsstationen der Vogelwarte Helgoland. *Der Vogelzug. Ber. ü. Vogelzugsforsch. u. Vogelberingung* 1(1): 34-40. Map. 1930.—The fall migration at Heligoland and neighboring positions of the coast is chiefly in a southwesterly direction. Passage over the sea is influenced by weather and by the form of the coast. Night migrants are much less influenced by coast lines than day migrants. Migration dates are given for several species at various points in 1928.

11947. FALLA, R. A. The Arctic tern (Sterna paradisea Brünnich). An occurrence in New Zealand. *New Zealand Jour. Sci. & Technol.* 12(1): 27. 1930.—Specimen taken near Wellington, Dec. 15.

11948. FLICKINGER, FREDERICK R., and LAWRENCE D. HIETT. Tern-ing around. *Bird-Lore* 32(4): 251-255. 4 pl. 1930.—Study of a nesting colony of common terms* in Ohio.

11949. FRIELING, HEINRICH. Eine Beobachtung an den Frohberger Teichen. [A year of observation on the Frohberg ponds, Saxony.] *Mitteil. Ver. Sächs. Ornithologen* 2(5): 201-208. 1929.—Migration and breeding records of water birds.

11950. GARLAND, H. B. Sabine's gull in Kent. *British Birds* 23(9): 250. 1930.—Sight record, Dec.

11951. GARNETT, R. M. White-spotted Bluethroat in Norfolk. *British Birds* 23(12): 339-340. 1930.—*Luscinia svecica cyanecula*, first record for Norfolk.

11952. GRINNELL, JOSEPH, and RICHARD HUNT. Notes on water birds at Morro Bay, California. *Condor* 31(2): 62-73. 3 fig. 1929.—Habits, dates of occurrence, weights, colors of soft parts, and other details are given for 59 spp.—*T. I. Storer.*

11953. GROTE, HERMANN. Wanderungen und Winterquartiere der paläarktischen Zugvögel in Afrika. *Mitteil. Zool. Mus. Berlin* 16(1): 1-116. 1930.—Most transients go to East Africa, but some western palearctic species visit West Africa. Many birds from west and middle Asia winter in Africa, especially in the northeast, even species from east Asia, as *Falco amurensis* and *F. pekinensis* migrate regularly to S. Africa for the winter. Few species spend the winter in Madagascar, palearctic passerine birds being entirely lacking. A detailed bibliography is given.—*H. Grote (transl. by M. M. Nice).*

11954. HADLEY, ALDEN H. A visit to Cobbs Island. *Bird-Lore* 32(4): 318-320. 1930.—Notes on nesting and migrating water birds on this Virginia island.

11955. HAIGH, G. H. CATON. Red-breasted flycatchers in Lincolnshire. *British Birds* 23(12): 339. 1930.—Two *Muscicapa p. parva* collected, Sept. 18 and 19.

11956. HAIGH, G. H. CATON. Albino pink-footed geese in Lincolnshire. *British Birds* 23(12): 340-341. 1930.—*Anser brachyrhynchus.*

11957. HALE, JAMES R. Ring-ouzel in Kent in July. *British Birds* 24(4): 106. 1930.—*Turdus t. torquatus.*

11958. HARWELL, C. A. Tree swallows of Yosemite. [California.] *Yosemite Nature Notes* 9(5): 35-36. 1930.—20 spp. observed in 1 day's observations, with note on the western bluebird (*Sialia mexicana occidentalis*).

11959. HOFFMANN, BERNH. Von zwei Ornithologen-Fahrten nach Hiddensee. [To be cont'd.] *Ornithol. Monatsschr.* 55(2): 17-24. 1 fig.; (3): 43-48; (4): 51-60; (5): 78-80; (6): 83-94. 1930.—An account of trips in 1928 and 1929 to this island on the coast of Pomerania and to other localities in north Germany. Previous papers on the birds of this island are cited. In the systematic list distribution and habits are discussed, and special attention is given to songs and call-notes.

11960. HOFFMANN, BERNH. Von zwei Ornithologen-Fahrten nach Hiddensee. [Two ornithological trips to Hiddensee Isl., Germany.] *Ornithol. Monatsschr.* 55(7): 100-110; (8): 118-126. [2 fig.] 1930.

11961. HUMPHREYS, G. R. Observations on the migration of birds at Irish light-stations during the year 1928. *Irish Naturalists' Jour.* 3(4): 83-89. 1930.

11962. HUTSON, H. P. W. The birds of Hong Kong. *Hong Kong Naturalist* 1(1): 2-7. 1 col. pl. 1930.—This is the first of a projected series of articles on the birds of the region. The species are rather limited in number though individuals are fairly numerous. The family Sturnidae, represented by 4 species, is treated in this installment, with a key and notes on habitats and habits.

11963. H[UTSON], H. P. W. Ornithology. *Hong Kong Naturalist* 1(1): 35-40. 2 pl., 1 fig. 1930.—*Megalaema virens** is recorded for the first time from Hong Kong, where it nested. Seasonal notes on migrants and nesting specis are given, and suggestions for bird study are made.

11964. **INGERSOLL, S. R.** Bird migration in Volusia County. *Florida Nat.* 3(4): 90-92. 1930.—The author records bird migrations in fall of 1929 and spring of 1930.

11965. **INGRAM, GEOFFREY C. S., and H. MORREY SALMON.** Lesser black-backed gulls in Glamorgan. *British Birds* 23(9): 250-252. 1930.—Breeding birds, *Larus fuscus affinis*, are present in this region from March to Nov. In winter some of the Scandinavian race, *L. f. fuscus*, have been observed, and apparently a few of the form *intermedius*, of Denmark and southern Norway.

11966. **JENSEN, J. K.** Nesting of the Piñon Jay, Cyanocephalus cyanocephalus, in New Mexico. *Oologists' Rec.* 10(2): 37. 1930.

11967. **JESPERSEN, P.** Distribution of some oceanic birds in the waters east of New Zealand. *Nature* [*London*] 126(3173): 280-282. 3 maps. 1930.—This paper is based upon observations of the Dana expedition in Dec., 1928, and Jan., 1929. Latitude 44° S. appeared to be the approximate line of demarcation between the distribution of certain birds breeding on North Isl. or farther north and that of certain other species breeding on South Isl. or farther south. In this connection it is noted that there is a rapid decrease in surface temp. from 17° to 14° C. between lat. 42° and 44° S., and also a great difference in the composition and kind of plankton. Thus the surface temp., by affecting the food for the birds, becomes an important factor in their distribution.

11968. **JOHNSTON, T. L.** Sabine's gull in Cumberland. *British Birds* 23(9): 250. 1930.—Specimen found dead, Dec.

11969. **JORDAN, K. H. C.** Zum Vorkommen des Haselhuhnes, Tetrastes bonasia rupestris (Brehm), in der sächsischen Oberlausitz. *Mitteil. Ver. Sächs. Ornithologen* 2(5): 209. 1929.—Record of one shot.

11970. **JOURDAIN, F. C. R.** First record of stock dove breeding in Bute. *Scottish Nat.* 1930(184): 126. 1930.—*Columba oenas*, in 1897.

11971. **KNAPP, G. ARTHUR.** Lapland longspur in Connecticut. *Bird-Lore* 32(3): 200. 1930.—Flock on March 30, sight record.

11972. **LODGE, S., and A. M. BAILEY.** Brewer's blackbird in the Chicago area. *Progr. Activities Chicago Acad. Sci.* 1(3): [10-11]. 1930.—First report of *Euphagus cyanocephalus* in this area.

11973. **LUNDSTRÖM, LLOYD V.** Fynd av storlabb (Stercorarius skua Brünnich.) vid Skälderviken. [Finding of S. skua in Skälderviken.] *Fauna och Flora* [*Stockholm*] 1930(2): 81-84. 1 fig. 1930.

11974. **MACPHERSON, A. HOLTE.** Birds of inner London. *British Birds* 23(10): 266-268. 1930.—Brief notes on a number of spp. supplementing a previously published list.

11975. **MASEFIELD, JOHN R. B.** Marsh-harrier in Staffordshire. *British Birds* 23(12): 340. 1930.—*Circus aeruginosus*, first specimen for Staffordshire.

11976. **MASEFIELD, JOHN R. B.** Glossy ibis in Staffordshire. *British Birds* 23(12): 341. 1930.—*Plegadis f. falcinellus.*

11977. **MEESON, P. M.** Breeding of the spotted crake in Somersetshire. *British Birds* 24(2): 56. 1930.

11978. **MEESON, P. M.** Breeding status of the garganey in Essex. *British Birds* 24(4): 108-109. 1930.—*Anas querquedula* an uncommon but regular breeder.

11979. **MEYER, VIKTOR.** Unsere Brutvögel auf Oehe-Schleimünde 1929. *Ornithol. Monatschr.* 55(5): 65-78. 2 maps. 1930.—A study and census of nesting water birds in a preserve on the coast of Schleswig-Holstein. A map shows the recovery of banded young *Larus canus* in other parts of Germany and in Netherlands, France, and England.

11980. **MEYLAN, O.** Notes sur les oiseaux des environs de Genève. 2me année-1929. *Bull. Soc. Zool., Genève* 4(2): 100-122. 1930.—This is a compilation of the notes of several observers on the distribution and habits of numerous birds of Switzerland.

11981. **MICHAEL, ENID.** Bird survey at el Portal. [California.] *Yosemite Nature Notes* 9(5): 38-40. 1930.

11982. **MICHAEL, ENID.** The common nesting birds of Yosemite Valley. *Yosemite Nature Notes, Spec. Bird No.* 9(6): 41-64. 19 fig. 1930.—Notes on 20 summer visitants and 16 permanent bird residents in Yosemite Valley, with chart showing first arrivals.

11983. **MICHAEL, ENID.** Yosemite bird report for June, 1930. *Yosemite Nature Notes* 9(8): 79-80. 1930.—A list of 50 birds with nesting notes.

11984. **MILLAR, G. R.** Nesting of the goosander in Selkirkshire. *Scottish Nat.* 1930(183): 87. 1930.—First record of the nesting of *Mergus merganser* south of the Firth of Forth in Scotland.

11985. **MOLTONI, EDGARDO.** Cattura di un rondone pallido (Apus murinus brehmorum Hart.) in Piemonte. [A. m. brehmorum taken in Piedmont, Italy.] *Atti Soc. Italiana Sci. Nat. e Mus. Civico Stor. Nat. Milano* 69(1): 42-45. 1 pl. 1930.

11986. **MÜNCHBERG, PAUL.** Die in den letzten Jahren in den Kreisen Landsberg und Schwerin (Grenzmark) beobachteten seltenen Durchzügler und Wintergäste aus der Vogelwelt. [Rare bird migrants and winter visitors recently observed about Landsberg and Schwerin, Germany.] *Helios* 30: 138-147. 1930.—Notes on numerous spp.

11987. **NASH, J. KIRKE.** Bird-life on Cramond Island. *Scottish Nat.* 1930(184): 111-115. 1930.—A general account of the birds of this small island in the Firth of Forth.

11988. **NELSON, Mrs. EARL.** The upland plover in Minnesota. *Bird-Lore* 32(3): 184-186. 1 pl. 1930.—Notes on song, call, and habits.

11989. **NICE, MARGARET MORSE.** The Harris Sparrow in central Oklahoma. *Condor* 31(2): 57-61. 1929.—*Zonotrichia querula* arrives Oct. 27-Nov. 1 and departs May 3 to 12. On Christmas censuses 82 to 450 were recorded in an eight-mile tract of diversified country. Harbor is taken in brush; food includes ivy berries, elm blossoms and seeds. The adult plumage through the winter shows no change save on the cheeks which go from buffy to gray. The black crown is in process of acquirement by March 1; only 5 to 10% of the autumn population has the black hood. There are 3 different individual notes uttered by members of the species under differing circumstances, besides the song (here described in detail).—*T. I. Storer.*

11990. **O'DONOVAN, M. J. W.** Occurrence of the white-fronted goose (Anser albifrons albifrons) in the United Provinces. *Jour. Bombay Nat. Hist. Soc.* 33(3): 716. 1929.—A note.

11991. **ORR, J. W.** A robin flight. *Bird-Lore* 32(3): 203. 1930.—Tens of thousands passing southeastward in Virginia, Jan. 22.

11992. **PERSSON, CARL.** Anteckningar om fågellivet i sydvästra Jämtland. [Notes on birds of Southwest Sweden.] *Fauna och Flora* 1930(3): 97-122. 8 fig. 1930.—Notes on 103 spp.

11993. **PITMAN, C. R. S.** The nesting of the Little Grebe, Poliocephalus ruficollis capensis (Salvad.), on Lake Bunyonyi in the Kigesi District of S. W. Uganda. *Oologists' Rec.* 10(2): 25-26. 1930.—Note.

11994. **PONCY, R.** Liste des 40 espèces de Palmipèdes observés dans le Port de Genève de 1890-91 à 1929-30. *Bull. Soc. Zool. Genève* 4(2): 164-165. 1 fig. 1930.—With notes on their relative numbers.

11995. **PONCY, R.** L'Hirondelle de mer tschegrava et les Sterniens dans le port de Genève (Alt. 375 m.) *Bull. Soc. Zool. Genève* 4(2): 168-170. 1930.—Notes on the occurrence and habits of 5 spp.

11996. **PYNNÖNEN, ALPI.** Mitteilungen über die Vögel Nord-Kareliens. *Ann. Soc. Zool.-Bot. Fennicae, Vanamo* 8: (7)-(18). 1929.—An annotated list of about 65 forms, many of which had not been recorded previously from northern Karelia, Finland.

11997. **RALFE, P. G.** Ornithology in the Isle of Man, 1929. *North West. Nat.* [*Arbroath, Scotland*] 5(2): 96-104. 1930.—Bird records, with notes, including recoveries of ringed birds and migration notes, compiled from reports furnished to the Manx Mus.

11998. **RINTOUL, LEONORA JEFFREY, and EVELYN V. BAXTER.** Bird notes from Skye. *Scottish Naturalist* 1930 (183) : 85-87. 1930.—A list of 23 of the more interesting species observed in May and June, 1930. Greenfinch, first record of breeding on Skye; tree-pipit, white wagtail, wood-warbler, and redstart, new to Skye.

11999. **ROBERTS, THOS. S.** Some changes in the distribution of certain Minnesota birds in the last fifty years. *Univ. Minnesota Mus. Nat. Hist. Occ. Papers* 3. 9-12. 1930.—Sixteen species have extended their ranges in Minnesota within this period. At first rare and irregular, most of them now occur regularly and breed. Eleven have come from the south,—red-bellied woodpecker, cardinal, Louisiana water-thrush, barn owl, prothonotary, blue-winged, and cerulean warbler, Bewick's and Carolina wrens, tufted titmouse, and blue-gray gnatcatcher. Six have come from the west,—Brewer's blackbird, western kingbird, burrowing owl, lark bunting, and McCown's longspur. The eastward movement of the last 2 species was finally stopped entirely by the extensive cultivation of the prairies.

12000. **ROCARD, M.** Contribution a l'étude de la faune ornithologique de l'ile de Noirmoutier [France]. *Rev. Hist. Nat. Appliquée Pt. 2. Oiseau et Rev. Franç. Ornithol.* 11 (6) : 351-360. 1930.—Notes on 31 birds of the Island.

12001. **ROGERS, NELL A.** Two unusual flocks of swans. *Science* 72 (1857) : 116. 1930.—Report of 2 large flocks of the rare *Cygnus columbianus* in Wisconsin.

12002. **ROWAN, WILLIAM.** Notes on Alberta waders included on the British list. Part 8. The nesting of the greater yellowshank. *British Birds* 24 (4) : 90-93. 2 fig. 1930.—Account of the nesting habits of *Tringa melanoleuca*, illustrated with the first known photograph of its nest.

12003. **RUSSELL, GEO. W.** Pink-footed goose as winter visitor to Shetland. *Scottish Naturalist* 1930 (183) : 68. 1930.

12004. **SCHAECK, F. de.** Sur un ouvrage manuscrit d'un avifauniste Genevois, Daniel Le Clerc, junior, de la deuxième moitié du XVIIIe siècle. *Bull. Soc. Zool. Genève* 4 (2) : 155-163. 1930.—This original work in Latin, recently brought to light, was a systematic treatise for the determination of the local species of birds. It is noteworthy for the local names, most of which are no longer in use, for the brief but precise data on habitats, migration, and food, and for records of rare species. In this review the local names are copied, and some of the rarer and more interesting records are quoted.

12005. **SCHARLEMAN, N.** Kreuzschnäbel und Tannenhäher in der Ukraine 1929. *Der Vogelzug* 1 (2) : 94-95. 1930.—Large numbers of crossbills began to appear about the 1st of June. At first the flocks consisted mostly of young birds, but by fall adults predominated. *Nucifraga c. caryocatactes* appeared in small numbers from Sept. to Nov.

12006. **SCHOUTEDEN, H.** Mes récoltes ornithologiques au Katanga. I. Environs d'Elisabethville. *Rev. Zool. & Bot. Africaines* 18 (3/4) : 277-290. 1930.—The avifauna of this region resembles in part that of the forest region of the central Congo, and in part that of the savanna region of East Africa and Rhodesia. A briefly annotated list of 148 forms is presented. *Plocepasser rufoscapulatus* Bütt. and *Notiospiza angolensis* Gmel. had not been previously recorded from the Congo.

12007. **SCHUZ, [E.].** Vom Frühjahrszug 1929 in Rossitten. [The spring migration of 1929 at Rossitten, East Prussia.] *Der Vogelzug. Ber. ü. Vogelzugsforsch. u. Vogelberingung* 1 (1) : 45-46. 1930.—Data on several unusual or noteworthy birds.

12008. **SEHLBACH, FR.** Ornithologische Beobachtungen aus dem Wesertale während des kalten Winters 1928-29. *Ornithol. Monatsschr.* 55 (1) : 4-11. 1930.—This extreme winter evidently reduced the numbers of certain species such as linnet, serin, nuthatch, tree creeper, dipper, kestrel, buzzard, barn owl, little owl, moorhen, kingfisher, and partridge. Other spp. seem to have been little affected.

12009. **SHARP, W. M.** The starling in West Virginia. *West Virginia Univ. Bull., Proc. West Virginia Acad. Sci.* 3 : 77-81. 1929.—This introduced *Sturnus vulgaris* began its invasion of the state in 1918-20 and practically completed it by 1926; though still unknown in some mountainous parts. The first flocks appeared in winter and departed northward for the summer. Now the species is a permanent resident. Food, relations with native birds, and future status are discussed.

12010. **SHULPIN, L.** Zosterops erythropleurus Swinh. im Ussuriland. *Jour. Ornith.* [*Berlin*] 78 (1) : 72-75. 1930.—This bird proves to be a fairly regular migrant and probable nester in the region. It appears in flocks in late May and in Aug. Notes on habits, color, and measurements are given.

12011. **S[OWERBY], A. de. C.** Peregrine falcon in Shanghai. *China Jour.* 13 (2) : 92-93. 1930.—*Falco peregrinus harterti* making its headquarters on a tower.

12012. **STEVENS, H.** [A recent trip in western China.] *Bull. British Ornith. Club* 50 (339) : 46-54. 1930.—The author describes his travels in Yunnan and Szechwan in 1928-29 as a member of the Kelley-Roosevelts Expedition of the Field Mus., and gives notes on numerous birds met with.

12013. **STRESEMANN, ERWIN.** Eine zweite Vogelsammlung aus Kwangsi. *Jour. Ornith.* [*Berlin*] 78 (1) : 76-86. 1930.—This is a report on specimens collected by S. S. Sin in the Yao-shan in 1928 and 1929. The species now known from the region number 181. The systematic list includes dates, wing measurements, and taxonomic remarks. There is a supplementary list of 63 forms, compiled from 2 recent papers published in Chinese by S. S. Sin.

12014. **STRESEMANN, ERWIN.** Eine dritte Vogelsammlung aus Kwangsi. *Jour. Ornith.* [*Berlin*] 78 (3) : 301-308. 1930.—This is a report on about 36 forms collected in the Yao-shan Mts. in 1929 by S. S. Sin. The treatment includes a list of specimens (with dates), wing measurements, and notes on manner of occurrence and on taxonomy.

12015. **SWAN, GRACE.** Arkansas Kingbirds in eastern Washington. *Bird-Lore* 32 (4) : 272-273. 1 pl. 1930.—Notes on nesting and other habits.

12016. **TANTZEN.** Die Verbreitung des Weissen Storches im Landesteil Oldenburg. *Jour. Ornith.* [*Berlin*] 78 (1) : 106-112. 2 maps. 1930.—Here, as elsewhere in Germany, the white stork is decreasing. This is not due to shooting nor to lack of nesting sites, but to drainage of marshes. The fertility of the species seems subject to fluctuation. In 1928 more than a quarter of the local storks reared no young. The nests abandoned since 1900 and those occupied in 1928 are indicated on maps.

12017. **THOMAS, J. F.** Redshanks breeding in Carmarthenshire. *British Birds* 24 (1) : 32. 1930.—*Tringa t. totanus*, first breeding records in that county.

12018. **TICEHURST, N. F.** Gadwall in Kent. *British Birds* 24 (4) : 108. 1930.—*Anas strepera*, first record in April.

12019. **URNER, CHARLES A.** The birds of Union County, New Jersey, and its immediate vicinity—a statistical study. *Abstr. Proc. Linnaean Soc. New York*, Nos. 39/40. 44-98. 2 map. 1927/28 (1930).—This paper presents the results of field studies on the seasonal occurrence of birds, chiefly during the period of 1916-1927. There are brief notes on the varying topography of this area, and conditions of bird life in 2 major types of habitat, salt marshes and uplands, are compared throughout. As a result of the increasing human population and industrial development, there has been a general decline in the bird life. Tables show the relative numbers of individuals of the various bird families among the breeding population; the numbers of each species nesting on a 236-acre tract; and the total number of species observed each month during a 12-year period. An an-

notated list of 276 forms includes extreme dates of occurrence, periods of average occurrence, the maximum number of each species seen on any one trip during each month, and the average number seen per trip during June.

12020. **WAGSTAFFE, R.** The birds of Great Saltee Island. *Southport Soc. Nat. Sci.* 24th Rept. 6-7. 1929/1930.—Summary of a lecture on the birds of this island off the Irish coast. The nesting of the hooded crow and the gannet, and the presence of a chough, were noteworthy.

12021. **WAHBY, ALY.** Les oiseaux de la région de Stamboul et ses environs. *Bull. Soc. Zool. Genève* 4(2): 171-175. 1930.—The author lists, with localities and dates, the species collected or observed since 1919, and adds migration notes on some of them.

12022. **WHISTLER, HUGH.** The birds of the Rawal Pindi District, N. W. India. *Ibis* 6(1): 67-119. 1930.—Annotated systematic list.—*W. W. Bowen.*

12023. **WILLIAMS, LAIDLAW.** Notes on the feeding habits and behavior of the California Clapper Rail. *Condor* 31(2): 52-56. 7 fig. 1929.—Observations on *Rallus obsoletus* on marshes of San Francisco Bay near Dumbarton Bridge showed that one particular bird had a regular forage route. The principal item of food was a clam, *Macoma balthica*, which was dug out, washed and then swallowed, entire in the case of small individuals the larger ones piecemeal.—*T. I. Storer.*

12024. **WITHERBY, H. F.** New British birds and alterations to the British List. *British Birds* 24(1): 22-25. 1930.—*Oenanthe deserti deserti* and *Phalacrocorax carbo sinensis* are added to the list. Three changes of names, already dealt with in previous literature, are discussed.

12025. **WITHERBY, H. F.** [An ornithological expedition in eastern Spain.] *Bull. British Ornith. Club* 50 (342): 74-79. 1930.—Includes notes on distribution, nesting, and taxonomy of various species.

12026. **WOHLFARTH, GERHARD.** Das Vogelleben um Frankfurt a. d. Oder. *Helios* 30: 73-137. 1930.—A list of 214 forms, with notes on status, migration, habitat, and habits.

12027. **ZDOBNITZKY, FRANZ.** Zweiter Beitrag zur Kenntnis der Vogelwelt der Brünner Umgebung und des südlichen Mährens. Verarbeitete Beobachtungen von 1910-1924 im Lichte der trinären Nomenklatur. *Verhandl. Naturforsch. Ver. Brünn* 61: 151-176. 1927/1929 (1930).—This installment includes 4 Alaudidae, 9 Motacillidae, and 2 Fringillidae, with notes on distribution, seasonal occurrence, habits, and taxonomy. A few observations by the author in Siberia are also included.

12028. **ANONYMOUS.** The bustard in China. *China Jour.* 12(3): 170-171. 2 pl. 1930.—*Otis dybowskii* winters abundantly in Chihli, Shansi, and Shensi, where the natives hunt it by means of decoys and blinds. The feathers are used for fans.

12029. **ANONYMOUS.** Invasion of crossbills from the continent. *Scottish Nat.* 1930(184): 109-110. 1930.—An extensive flight in Scotland in July and Aug., 1930.

12030. **ANONYMOUS.** Leach's fork-tailed and storm-petrels inland. *British Birds* 23(9): 253-254. 1930.—Records of a number of *Hydrobates pelagicus* and of *Oceanodroma l. leucorrhoa* in England, picked up dead or dying after stormy weather.

MAMMALIA

GERRIT S. MILLER, *Editor*

REMINGTON KELLOGG, *Associate Editor*

(See also in this issue Entries 9095, 9196, 10443, 10747, 11234, 11247, 11295, 11296, 11304, 11327, 11343, 11352, 11374, 11375, 11398, 11484)

12031. **ANTONIUS, OTTO.** Streitfragen zur Phylogenie der Equiden. *Verhandl. Zool.-Bot. Ges. Wien* 78 (1): 4-18. 2 fig. 1928.—Answering the criticism of J. U. Duerst, the author maintains the geological position of *Equus abeli* as that of the Early Quaternary and its phylogenetic position as nearest that of the Taubach horse. He considers Spain the center of origin of the heavy domestic horse with a long, small skull and ram-like head. He criticizes Schwarz's use of trinomials and acceptance of the law of priority in paleontology. He maintains the distinctness of the extinct tarpan of south Russia from the oriental domestic horse. He points out Matthew's error in considering the "pli caballin" absent in the upper molars of the ass, and discusses other details of Matthew's recent work.

12032. **ATHANASIU, SAVA, and D. M. PREDA.** Stratigrafia basinului inferior al Trotuşului. II. Elephas meridionalis din Pliocenul Superior dela Pralea-Căiuţi (Distr. Bacău). [E. meridionalis in the Upper Pliocene of Pralea-Căiuţi.] [French summary.] *Anuar. Inst. Geol. României* 13: 65-84. Map, 2 pl., 1 fig. 1928(1929).—From the lignite beds associated with fragments of *Rhinoceros* cf. *etruscus*, 3 incomplete molars are described.

12033. **BLACK, DAVIDSON.** Interim report on the skull of Sinanthropus. *Bull. Geol. Soc. China* 9(1): 7-10. 6 pl. 1930.—Probably not far removed from the type from which evolved both the extinct Neanderthaler and the modern *Homo sapiens*.

12034. **BOBRINSKOJ, N.** Bats of Central Asia. Ежегодник Зоологического Музея, Академия Наук СССР. (*Ann. Mus. Zool., Acad. Sci. URSS.*) 30(2): 217-244. 5 fig. 1929.—22 spp. and sspp. are listed with notes on distribution and systematics; synonymy is given, and comparative measurements in 5 tables. Diagnoses of *Myotis mystacinus przewalskii** Bobr.; *M. m.* **kuk**-norensis *Balekut-gomi* on Huang-ho R. to the south from Lake Kuku-nor (p. 221); *Eptesicus caucasicus pallescens** Bobr.; *E. alashanicus** Bobr.—*G. Maydell.*

12035. **CABRERA, ANGEL.** Más sobre los leopardos africanos. *Bol. R. Soc. Española Hist. Nat.* 28(1): 79-94. 1928.—The author disagrees with J. A. Allen's conclusion, and supports Thomas in fixing the type locality of Linnaeus' *Felis pardus* as the Nile valley of Egypt, instead of Algeria, so that the northeastern race, *Panthera nimr*, recognized by Allen, becomes a synonym of *pardus*. The author admits that the leopard he named *Panthera pardus reichenowi* in 1918, from northern Cameroon, is a ♀ and not a ♂, thus accounting for its small size, as at first supposed, but maintains the probability that the name is valid for the open country form; whereas for the forest region from Lake Kivu to the West Coast there is but a single recognizable ssp., to which *Felis pardus centralis* Lönnberg is applicable, except that the name is preoccupied by *Felis centralis* Mearns (1901) for a race of Central American jaguar. The correct name for the forest leopard of central Africa is, therefore, *Panthera pardus ituriensis* J. A. Allen, the next name available. The author points out, further, the absurdity of recognizing distinct spp. of leopard in East Africa, to which the names *fortis*, *chui*, and *suahelica* have been given, but admits the probability that in various parts of the range, the forest-living leopards differ subspecifically from those of open country.—*G. M. Allen.*

12036. **COOK, HAROLD J.** New rhinoceroses from the Pliocene of Colorado and Nebraska. *Proc. Colorado Mus. Nat. Hist.* 9(4): 44-51. 7 pl. 1930.—*Paraphelops* **yumensis*** (p. 44), ? *Peraceras* **ponderis*** (p. 45), and *Aphelops malachorhinus* **longinaris*** (p. 45), Colorado, types in Colo. Mus. Nat. Hist.; **MESOCERAS** (p. 49), n. subg. of *Teleoceras*, erected for *T.* **thomsoni*** (p. 49), Ne-

braska, type in author's coll.; also including *T. mediocornutus* Osburn.

12037. [FLEROV, K. K.] ФЛЕРОВ, К. К. Очерк фауны млекопитающих долины реки Чороха. [Mammal fauna of the valley of the river Chorokh.] Ежегодник Зоологического Музея, Академия Наук СССР. (*Ann. Mus. Zool., Acad. Sci. URSS.*) 28(1): 63-71. 1927.—Notes on 24 spp. of mammals with a table of comparative measurements.—*G. Maydell.*

12038. GRANDIDIER, G., et G. PETIT. Étude d'un mammifère insectivore malgache, le Geogale aurita A.M.E. et A. G. In: Faune Colonies Françaises 4(4): 441-493. 20 fig. 1930.—The varying opinions of zoölogists on the systematic position of this rare mammal* are cited. On the basis of new material, the present authors furnish a detailed comparative study of its external and internal morphology. The typical form is restricted to the western part of the island, and a new ssp., *G. aurita* orientalis (p. 446), is described from the east coast; type in coll. G. Grandidier. The sp. shows affinities with both the Oryzoryctinae and the Centetinae (subfamilies of the Centetidae), and it may constitute a separate subfamily intermediate between the other two.

12039. HELLER, FLORIAN. V. Palaeozoologie, Vertebrata. Murmeltierreste aus dem jüngeren Löss von Nebra [Saxony]. *Leopoldina* 6: 581-586. 2 pl. 1930.—Two well preserved marmot skulls are described, with the hope of settling the relationships of diluvial marmots. The author believes that these forms should be classed with *A. primigenius* rather than with *Arctomys bobac* or *A. marmotta*. The smaller skull was broken, presumably by a bird of prey.—*F. Heller* (*transl. by A. E. Wood*).

12040. HOARE, W. H. B. Conserving Canada's musk-oxen. Being an account of an investigation of Thelon Game Sanctuary 1928-1929 with a brief history of the area and an outline of known facts regarding the musk-ox. [With appendix B: "Notes on the musk-ox and the caribou" by R. M. ANDERSON.] 53p. Illus. Published by Canada Dept. Interior, Northwest Territories & Yukon Branch, 1930.

12041. KAVANAGH, E. N. The Roosevelt elk, Cervus roosevelti Merriam. *Jour. Forest.* [*Washington*] 28(5): 659-663. 1930.—The taxonomic and ecological characteristics of the Roosevelt elk, inhabiting the Olympic Peninsula in northwestern Washington, are given.—*P. C. Wakeley.*

12042. KELLOGG, REMINGTON. The history of whales—their adaptation to life in the water (concluded). *Quart. Rev. Biol.* 3(2): 174-208. 13 fig. 1928.—A detailed osteological comparison of the skulls of extinct and contemporary whales, by families. Morphological peculiarities of the mysticetes. Anatomical and physiological adjustments of the body to meet the needs of aquatic existence. Detailed discussions of the eye and cerebellum and of the olfactory apparatus and olfactory lobes.—*P. Bonnot.*

12043. KOCH, W. Über angebliche Anzeichen von Domestikation am Skelett von Rindern. *Zeitschr. Wiss. Biol. Abt. A, Morph. u. Ökol. Tiere* 7(3): 444-471. 6 figs. 1927.—Domestication of Bovinae does not always lead to decrease in size. There is no notable difference in size between *Bos taurus primigenius* Boj. and large modern domestic cattle; nor between wild and large domesticated specimens of *Bos grunniens*. Great weight and firmness and roughness of the skeletal surface are no signs of wildness, but of age. Existing differences in the skeleton, especially in cervical and thoracic vertebrae, are attributable to influence of size of horns. Furrowings and varying surface structure of the frontal peg or occurrence of bony accretions at the base, are not characters differentiating wild and domestic forms; they are signs of age. On such basis, age can be determined very well. No generally valid points of differentiation between wild and domesticated cattle have hitherto been found. Determination occasionally rests largely upon differences in size and form of horns. The alleged primitive stock of the domesticated form (*Bos europeus* Adametz) is denied, as the wild type can not be ascertained. *Bos taurus primigenius* Boj. is indicated for the first time for southern Bavaria.—*W. Koch* (*transl. by E. W. Count*).

12044. KOCH, W. Das Gehörn der Schraubenziege (Capra falconeri Wagn.). *Zool. Anz.* 93(7/10): 275-278. 2 fig. 1931.—In direction of spiral winding, in basal outline, and other characters, the horns of the markhor, *C. falconeri**, are the reverse of those of *C. hircus**. Since intermediates are impossible, the latter can not have been derived from the former species.

12045. KOLLER, OTTO. Säugetiere aus Tunis, gesammelt von Alfred Weidholz, 1912. *Ann. Naturhist. Mus. Wien* 44: 1-4. 1930.—An annotated list of 17 spp. from the Mus. Nat. Hist., Wien.

12046. KRIEG, HANS. Biologische Reisestudien in Südamerika. XVI. Die Affen des Gran Chaco und seiner Grenzgebiete. *Zeitschr. Wiss. Biol. Abt. A, Morph. u. Ökol. Tiere* 18(4): 760-785. 14 fig. 1930.—The genera *Callithrix*, *Callicebus*, *Aotes*, *Alouatta*, *Cebus*, *Saimiris*, and *Ateles* are considered. The treatment is mainly of a zoogeographical-ecological nature, especially of what can be observed of the animals in their natural environment. As in the author's previous work on this expedition, the environment and climate are described, in which the animals live. The main types are the flood region of the eastern Chaco, the dry bush of the western, the wooded region of the eastern slope of the Bolivian Andes, the Amazon-type tropical rain forests which bound the Chaco on the northwest, and the Chiquitos region which is especially interesting zoogeographically and which bounds the Chaco plain on the north. This region is transitional between tropical virgin forest and the dry region lying to the south of it. The relations between mode of life and body proportions of the monkeys observed are given. Members of the genera *Callithrix*, *Aotes*, and *Callicebus*, which all have long flexible tails [Schlaffschwänze], must be definitely classed as "jumpers." This is well seen in the much greater length of the hind limbs as compared with the fore limbs. In opposition to this, *Alouatta* and *Ateles* have the tail formed into a gripping organ, and the forelimbs into long gripping hooks, while the hind limb is relatively short and the jumping mode of progression is completely absent or nearly so. A mean between the two types is *Cebus*, in which the tail is a facultative gripping organ, and the limb proportion approaches the "jumper" type.—*H. Krieg* (*transl. by R. M. Bond*).

12047. KUNTZE, ROMAN. Przyczynek do znajomości fauny Ssaków południowej Polski. [Notes on mammals of southern Poland.] [German summary.] *Kosmos* [*Lwów*] 55(1/2): 219-232. 1 fig. 1930.—The distribution and ecology of several spp. are discussed. *Putorius lutreola*, supposed extinct here for 30 years, is recorded in 1914 and 1924. *Glis glis* occurs chiefly in the foothills of the Carpathians. *Dyromys nitedula* occurs in the Carpathians up to 1300 m. and also spreads over the lowland to northeastern Poland. *Muscardinus avellanarius* is recorded up to 1000 m. in the Carpathians. *Evotomys glareolus* consumed about 80% of the beech and oak mast on 3 ha. In a plague of *Microtus arvalis*, leucistic (white-haired, black-eyed, epidermally pigmented) individuals were observed. *Microtus agrestis* is recorded from 1400 m. in the Carpathians—the second known locality for the sp. in Poland.

12048. LAGRANGE, E. L'autotomie de la queue chez un mammifère (Acomys cahirinus). *Arch. Internat. Physiol.* 33(3): 225-228. 1931.—*Acomys cahirinus*, a small Egyptian rodent, when seized by the tail, escapes, leaving the skin of the tail in the captor's hands; later the tail dries up and drops off. Experiments showed that this "autotomy" does not occur before the 6th week of life. The tail of the young rodent shows a distinct constriction, which disappears as the mechanism of autotomy becomes established. A weight of 400-500 gm. or more (the animal itself has an average weight of less than 40 gm.) was necessary to pull the skin off the tail by force in 10-20 sec. Burning or pinching the tail did

not produce detachment. The author concludes that the act is voluntary and coordinated especially with fear and the desire to escape; not with that of avoiding pain.

12049. **LIEBUS, ADALBERT.** Quartäre Säugetierreste aus der Barrande-Grotte. *Naturwiss. Zeitschrift Lotos.* 76(8/12): 347-350. 1 fig. 1928.—Discovery of the Barrandegrotte in Srbsko near Berau (Bohemia) led to the finding of a number of scattered bones, presumably of recent origin. The author identified the following: *Gulo luscus**, left mandible, right femur, a fragment of the first phalanx of the 5th toe; exact measurements are given of the mandible and of the femur; *Mustela martes*, 2 skulls, 1 mandible; *Lupus spelaeus*, 1 calcaneum and a fragment of the proximal end of the femur. In addition, remains of Artiodactyla, 1 ungual phalanx, 1 phalanx, and 2 fragments of molars, were also identified. —*A. Liebus (transl.)*

12050. **LINDSAY, HELEN M.** Scientific results from the mammal survey. No. 48. Indian shrews. *Jour. Bombay Nat. Hist. Soc.* 33(2): 326-340. 1929.—Habitat and character analysis of 24 spp. and sspp. of the genus *Suncus*, including *S. niger* malabaricus (p. 334), Coorg and Cochin, at 3000 ft. altitude.—*J. T. Nichols.*

12051. **MILLER, FREDERIC W.** A new Colorado pocket gopher of the genus Thomomys. *Proc. Colorado Mus. Nat. Hist.* 9(3): 41-43. 1 fig. 1930.—*T. talpoides* macrotis* (p. 41), along the Cherry Creek bottoms in Douglas Co., Colorado.

12052. **MURR, ERICH.** Zur Erklärung der verlängerten Tragdauer bei Säugetieren. *Zool. Anz.* 85(5/8): 113-129. 1 map, 2 fig. 1929.—The extended period of gestation, in agreement with their closest relatives, of many indigenous mammals (martin, roe, badger, bear, bat), which has been elucidated for the martin in the North American fur farms, is looked upon as an expression of a great physiological age, as the retention of primitive characters (Prell 1927). Comparative investigations with consideration of climate and geographic relations show that more or less prolonged periods of gestation seem to occur in numerous relatives of these animals, and make it much more probable that low temperatures of the present or earlier habitat, because of periodic lack of food, and other factors, have tended to prolong the intrauterine development (labile homoiothermism). By such a transition from the historical to the physiological point of view, the problem becomes accessible to experimental treatment; at the same time the direct influence of the endocrine glands might be considered.—*E. Murr (transl. by J. E. Lynch).*

12053. **NELSON, J. W.** The Columbian black-tail deer of the California National Forest. *Jour. Forest. Washington* 28(5): 664-667. 1930.—Notes on food and habitat are given.—*P. C. Wakeley.*
